The presence of one part of oxygen in ten million parts of hydrogen can be detected by means of the pressure changes which accompany the point discharge.

When nitrogen is present with oxygen in hydrogen, even in large excess, the combination which takes place is chiefly, and perhaps entirely, between the oxygen and the hydrogen. H. M. D.

Does the Law of the Action of Mass Hold for the Silent Electrical Discharge? Max Le Blanc and John H. Davies (Zeitsch. Elektrochem., 1908, 14, 361—366).—When dry ammonia gas is exposed to the silent discharge at constant temperature and constant current, the rate of decomposition is nearly proportional to the pressure. Temperature has a comparatively small influence on the rate of decomposition; a rise of 100° nearly doubles it. An increase of the current of one-third nearly doubles the rate of decomposition. The presence of excess of hydrogen diminishes the rate of decomposition, whereas nitrogen increases it. The luminosity of the discharge is much increased by nitrogen, but not by hydrogen. The final condition of equilibrium attained is found to be very little affected by the strength of current used. The ratio $[\text{N}_2]/[\text{H}_2]^3/[\text{NH}_3]^2$ for different mixtures of hydrogen and nitrogen is not even roughly constant. The law of mass action therefore does not hold. Apparently, it is only true when the temperature is so high that the reactions occur under the influence of heat alone.

T. E.

Volatilisation of Cathodes in Attenuated Gases. Franz Fischer and Otto Hähnel (Zeitsch. Elektrochem., 1908, 14, 366—367).—The authors have compared the volatilisation of different cathodes with the same current by using two discharge tubes in series. With the same metal and gas, the volatilisation is approximately inversely
proportional to the gas pressure and directly proportional to the square of the current density. The volatilisation in argon and hydrogen is the same; it is less in air than in hydrogen. The order of volatility of the metals is aluminium, iron, nickel, copper, platinum, silver. If the tubes are in parallel, the current passes more readily through argon than hydrogen, and the volatilisation in the argon tube is greater. Kohlschütter and Goldschmidt (this vol., ii, 457) find that different gases favour volatilisation in the order of their atomic weights. This is not in agreement with the present experiments, and is also contradicted by Kohlschütter and Goldschmidt's results when these are calculated for equal quantities of electricity.

Electrocapillary Measurements by the Method of Large Drops. Léon G. Gouy (Compt. rend., 1908, 148, 1374—1376).—The present paper deals with absolute measurements by means of a modified capillary electrometer. In order to obtain a rigorously hemispherical drop, the mercury is contained in a glass vessel, optically worked, and of 40 mm. radius. Results are given for solutions of hydrogen sulphate, sodium sulphate, hydrogen chloride, potassium bromide, and potassium iodide.

Determination of the Dielectric Constant of Helium. Ernst Hochheim (Ber. deut. phys. Ges., 1908, 6, 446—448).—The author has measured the dielectric constant of helium by the electrostatic null-method of Hopkinson-Lebedeff. The mean value reduced to 0° and 760 mm. pressure is \( D = 1.000074 \pm 0.000004 \). If the mean value \( n \) of the refractive index of helium is taken from the measurements of Scheel and Schmidt, Ramsay and Travers, and of Rayleigh, the relationship of Maxwell, \( D = n^2 \), is found to be satisfied.

Electrical Conductivity of Solid Cuprous Iodide. Karl Bädeker and E. Pauli (Physikal. Zeitsch., 1908, 9, 431).—The electrical conductivity of cuprous iodide, which is abnormally high for a transparent substance, is found to diminish with time. By subjecting a very thin film of copper to the action of iodine vapour in a suitable apparatus, an initial maximum specific resistance equal to 0.01 ohm, was obtained for the iodide. In an atmosphere saturated with iodine vapour, the conductivity remains unchanged, but falls immediately when the iodine vapour is removed by a current of hydrogen or air. On saturating again with iodine vapour, the original high value of the conductivity is attained, and the transformation can be repeated with the same specimen of cuprous iodide as often as desired.

A Peculiar Type of Electrical Conductivity. Karl Bädeker (Physikal. Zeitsch., 1908, 9, 431—433. Compare preceding abstract).—The rise of the electrical conductivity of cuprous iodide which is observed when the substance is brought into contact with saturated iodine vapour or a saturated iodine solution takes place asymptotically; approximately four-fifths of the total increase is observed in the first minute. The increase in the conductivity is accompanied by a slight darkening of the colour and by an increase in weight. The maximum
increase in weight of the substance when in an atmosphere of iodine corresponds with the addition of 0.00333 gram of iodine per gram of cuprous iodide. The proportion of absorbed iodine depends on the temperature and also on the pressure of the iodine vapour, or on the concentration of the iodine in the solution with which the cuprous iodide is in contact. Extremely small iodine vapour pressures or concentrations are, however, very active. The conclusion is drawn that the conductivity induced by the absorption of iodine is metallic in nature; the resistance is the same whether measured by direct or alternating currents, and prolonged passage of a direct current produces no change in the conductivity. The increase in conductivity observed when cuprous iodide is acted on by light is attributed to the separation of traces of iodine.

H. M. D.

Binary Electrodes and Electrochemical Adsorption. Leonor Michaelis (Zeitsch. Elektrochem., 1908, 14, 353—355).—By a binary electrode the author means a substance which sends out positive and negative ions when it dissolves. An acid of small solubility and high molecular weight sends out hydrogen ions and also anions; it may possibly continue to send these out after the solution is saturated; the ions will re-combine, and the undissociated molecules produced will separate out in the solid form. Owing to the different rates of diffusion of the hydrogen ions and the anions, the former will tend to escape from the surface of the solid, leaving it negatively charged. It therefore behaves like a hydrogen electrode, and the difference of potential between it and the solution depends on the concentration of the hydrogen ions in the solution. The addition of an acid diminishes the potential difference, and therefore increases the surface tension of the solid particles. The precipitation of a suspension of mastic by acids is explained in this way. The precipitation by a basic colouring matter, such as methyl-violet, is explained by the formation of a salt on the surface of the mastic particles. This diminishes the tendency to send out hydrogen ions, and so diminishes the potential difference and increases the surface tension. This theory is the opposite of that which explains adsorption as a pure surface effect due to the tendency of all substances to take on the form with the smallest surface tension.

T. E.

Thermodynamics of Liquid Cells. P. Henderson (Zeitsch. physikal. Chem., 1908, 63, 325—345. Compare Abstr., 1907, ii, 426).—The formula deduced in the earlier paper (loc. cit.) has been tested by measurements of the P.D. between equally concentrated solutions containing bivalent ions, such as $\text{SO}_4^-$, Ba, Cd, &c. The agreement between the observed and calculated values is fair. In respect to ease of manipulation, the author’s formula is superior to Planck’s, and the results which it gives are quite as satisfactory. An extension of the formula to concentrated solutions is deduced, and tested by measurements of the E.M.F. of the cell:

<table>

J. C. P.
Change of Free Energy Accompanying the Formation of Some Fused Salts of the Heavy Metals. Richard Lorenz and M. G. Fox (Zeitsch. physikal. Chem., 1908, 63, 109—120). —The authors describe a form of chlorine or bromine electrode suitable for use at high temperatures, consisting of a hollow carbon tube kept charged with the halogen, and show that this electrode is reversible. The variation of E.M.F. with temperature has been determined for a number of cells containing fused salts, and the results are represented by the following formulae: in these $e_{AB}$ means the E.M.F. of the cell $A | AB | B$, $AB$ being the fused salt formed from the elements $A$ and $B$.

$$e_{PbCl_2} = 1.263 - 0.00679 \ (t - 498^\circ)$$ for the temperature-interval 498—660°;  
$$e_{CaCl_2} = 1.258 - 0.00750 \ (t - 560^\circ), \text{ valid between } 560^\circ \text{ and } 740^\circ;$$  
$$e_{PbBr_2} = 1.0945 - 0.000714 \ (t - 367^\circ), \text{ valid between } 367^\circ \text{ and } 640^\circ;$$  
$$e_{CaBr_2} = 1.045 - 0.000742 \ (t - 580^\circ), \text{ valid between } 580^\circ \text{ and } 720^\circ$$

J. C. P.

Thermodynamics of Cells with Fused Electrolytes. Richard Lorenz and M. G. Fox (Zeitsch. physikal. Chem., 1908, 63, 121—125. Compare preceding abstract). —The Gibbs-Helmholtz formula is applied to the cells referred to in the preceding abstract, and the heats of formation of lead chloride and bromide and cadmium chloride and bromide are calculated. The values so found for the four salts are respectively 82.4, 71.5, 86.8, and 77.3 Cal. These figures represent the heats of formation at constant pressure in the temperature-intervals recorded in the previous abstract. So far as comparison is possible, the agreement with the values deduced thermochemically is fair.

J. C. P.

Differences of Potential at the Contact of Two Electrolytes. Nernst's Theory. J. Guyot (J. Chim. Phys., 1908, 6, 424—491). —Although the general formula for the potential difference at the contact of two electrolytes have not yet been obtained, it is shown theoretically that the calculation is not only possible for binary electrolytes with univalent ions (Nernst, Planck), but also for any two electrolytes of the same type (for example, BaCl$_2$, CaCl$_2$), as well as for electrolytes with a common ion when the total ionic concentration is the same for the two solutions. Direct experimental verification of the formula is not possible, owing to the fact that no single potential difference is known with accuracy; in particular, it is pointed out that the Helmholtz-Ostwald method for determining single potential differences, depending on electrolycapillary phenomena, is not trustworthy.

Measurements have therefore been made with "liquid chains," in which two solutions are in contact with each other and with mercury electrodes, forming cells of the type $M|S_1|S_2|M$. The total E.M.F. of such a cell is the algebraic sum of the potential differences at the two junctions metal|solution, and that at the junction of the two solutions $S_1|S_2$. As the former can be calculated for electrodes of the same metal by the usual formula $E = RT/nF\log_{p_2}/p_1$, the E.M.F. $S_1|S_2$ is readily obtained. For solutions of salts of the same type, measurements were made with alkali sulphates against sulphuric acid.

J. C. P.
and against each other, and for solutions of salts of different types such couples as HCl, BaCl₂, H₂SO₄|CuSO₄, and Na₂SO₄|ZnSO₄ were used. A few measurements were also made with liquid chains with identical extremities, for example,

\[ 0.1 \text{NK}_2\text{SO}_4 \cdot 0.2 \text{MLi}_2\text{SO}_4 \text{ and } 0.02 \text{NH}_2\text{SO}_4 \cdot 0.1 \text{NK}_2\text{SO}_4 \]

the E.M.F.'s at the junction metal|solution being thus eliminated. In all cases, the observed and calculated values were in satisfactory agreement.

G. S.

A Method for the Calculation of Ionic Concentrations from Measurements of Potential in Concentration Cells. WARREN KENDALL LEWIS (Zeitsch. physikal. Chem., 1908, 63, 171—176).—A method is given for calculating the dissociation of an electrolyte from potential measurements in concentration cells. Applied to the experimental determinations of Cumming with silver nitrate (this vol., ii, 253), very close agreement is obtained. New determinations with lead nitrate and chlorate are also given, the value for the normal lead electrode obtained being 0·402. The advantage of the method in the case of multivalent ions is that it is unnecessary to make any assumption as to dissociation in successive stages.

C. H. D.

Electrochemical Equivalent of Silver, Especially in Reference to the So-Called Anode Liquid. FRIEDRICH KOHLRAUSCH (Ann. Physik, 1908, [iv], 26, 580—596).—The author has made experiments to ascertain whether the value obtained for the electrochemical equivalent of silver by F. and W. Kohlrausch in 1881, and 1883, requires correction in the light of recent researches on the properties of the anode-liquid. According to these, oxidation products are formed in the solution at the anode, and this leads to inaccurate values for the equivalent. Using the original pieces of apparatus and duplicates of these, the new experiments show that the arrangement of the electrodes is such that the abnormal properties of the anode-liquid do not exert any influence on the result obtained. The correction which might be applied to the value 0·01183 given by the older experiments is at any rate less than 0·002%.

H. M. D.

A Lecture Voltameter. R. PITONI (Nuovo Cim., 1908, [v], 15, 426—428).—The voltameter is of the Hofmann pattern, but the three tubes are of equal diameter and in the same plane. Each is fitted with an electrode, and the centre tube also has an outlet tube and tap at the lower end. In the electrolysis of water, the central electrode may be made the anode, and the two outer ones cathodes; the volume of gas collected in each tube is then equal. The application of the voltameter to polarisation experiments is also described.

C. H. D.

Relation between the Ionising Power and the Dielectric Constants of Solvents. HERBERT N. MCCOY (J. Amer. Chem. Soc., 1908, 30, 1074—1077).—Walden has shown (Abstr., 1906, ii, 149) that when solutions of an electrolyte in various solvents have the same degree of dissociation, the product of the dielectric constant and the
cubic root of the dilution for such solutions is a constant, or \( \epsilon^3 \sqrt{V} = \) const. Kohlrausch's equation \( \Lambda = \Lambda_\infty - k \sqrt[3]{C} \), where \( \Lambda \) is the equivalent conductivity at concentration \( C \), \( \Lambda_\infty \) the conductivity at infinite dilution, and \( k \) is a constant, may be written \( \Lambda/\Lambda_\infty = 1 - k/\Lambda_\infty \sqrt[3]{C} \) or \( a = 1 - K \sqrt[3]{C} \) (1), where the degree of ionisation \( a = \Lambda/\Lambda_\infty \) and \( k/\Lambda_\infty = K \), a constant. From equation (1) the expression \( K = (1 - a) \sqrt[3]{V} \) (2) is obtained. The data for sodium chloride are tabulated, in which the values of \( a \) are calculated by equation (1). Similar calculations have been made for about thirty other salts. The differences between the observed and calculated values of \( a \) do not exceed the probable experimental error. It is shown that equation (1) applies fairly accurately to many solutions in inorganic solvents, and the values of \( K = (1 - a) \sqrt[3]{V} \), \( \epsilon \), and \( K \epsilon \) for tetraethylammonium iodide in various solvents are calculated from Walden's data. The results are also given for potassium iodide in water, ethyl alcohol, and acetone trile, and for lithium nitrate in water, methyl alcohol, and 50% methyl alcohol. In the case of potassium iodide, the value of \( K \epsilon \) is nearly the same for ethyl alcohol as for water, but is abnormally large in acetone trile. For lithium nitrate, \( K \epsilon \) has the same value for water and for methyl alcohol.

Electrolytic Rectification of Alternating Currents. Günther Schulze (Zeitsch. Elektrochem., 1908, 14, 333—347).—The author's experiments with direct current (Ann. Physik, 1906, 21, 929; 1907, 22, 543; 23, 226; 24, 43; 1908, 25, 775) have shown that the active electrode in an electrolytic rectifier is covered with a porous, non-conducting skin. The pores next to the metal are filled with gas, and the remainder are full of the electrolyte. When the electrode is cathode, negative corpuscles pass from it through the gas layer to the electrolyte without much resistance; when the electrode is anode, however, the carriers of the current in the electrolyte are anions which cannot pass through the gas layer. In the anode direction, the gas layer has a resistance of the order of 500 ohms per sq. decimetre; it also has a capacity of the order of 5 microfarads per sq. decimetre, and with alternating current of 50 periods per second, this allows the same current to pass as a resistance of 640 ohms. The resistance of the electrolyte is negligible compared with this, so that the current in the anode direction is conditioned by the resistance and capacity of the gas layer. In the cathode direction, the resistance of the gas layer and of the electrolyte are each of the order of 10 ohms per sq. decimetre; the capacity of the gas layer is therefore negligible. The theoretical shape of the current and E.M.F. curves are deduced from these considerations. A large number of curves are taken by means of an oscillograph, using electrodes of all the active metals known. The curves agree well with the theoretical forms. As a criterion of the relative values of the cells, the ratio of their apparent resistances in the cathode and anode directions is used. With aluminium in solutions of salts of potassium or sodium, the ratio is small, but the active layer soon breaks down. The danger of breakdown is smaller with ammonium salts, but the ratio is larger. Breakdown is never observed with
tantalum, but the ratio is much too large; its ability to resist E.M.F.'s of 1000 volts is of no use in practice, because of the very dilute solutions required. Magnesium has a very small ratio of resistances, but the active layer is very sensitive to rise of temperature. Since the liability to breakdown and a small ratio of resistances appear to be both due to the same cause (solubility of the solid skin in the electrolyte), it is improbable that a satisfactory electrolytic rectifier will be discovered.

T. E.

Theory of Dulong and Petit's Law. II. FRANZ RICHARZ (Zeitsch. anorg. Chem., 1908, 59, 146—160. Compare this vol., ii, 562).—A theoretical discussion of the causes which lead to deviations from Dulong and Petit's law. The author's theory, which requires that the product of the atomic weight and the specific heat at constant volume should be equal to 6·012, cannot be tested directly by ordinary experimental data. That elements of small atomic weight and small atomic volume represent exceptions is anticipated by the author's theory. In accordance with this, it is also found that of two allotropic modifications, the one with the smaller atomic volume has the smaller specific heat.

H. M. D.

Equation of Condition for Metals. MAX THIESEN (Ber. deut. phys. Ges., 1908, 6, 410—415, 415—417. Compare Grüneisen, this vol., ii, 563).—A discussion of conclusions regarding the equation of condition, which may be drawn from the relationship pointed out by Griineisen, that for a number of metals the quotient of the coefficient of expansion by the specific heat is almost independent of the temperature. The significance of this relationship depends on whether the equation of condition for a solid, crystalline substance is different from the equation for the same substance in the liquid condition or in another crystalline form, or whether the same equation of condition holds for all forms of the substance. In the first case, the relationship may be strictly true for certain crystalline forms, but in the second case the relationship can only be regarded as approximately valid for a finite portion of the curve of condition.

H. M. D.

Specific Heat and Molecular Magnetic Field of Ferromagnetic Substances. PIERRE WEISS and PAUL N. BECK (Arch. Sci. phys. nat., 1908, iv, 25, 529—548).—The energy transfer when ferromagnetic substances are magnetised or demagnetised by alterations in temperature is of the same order as the energy required to effect the temperature change itself.

The authors endeavour to show that the anomalies exhibited by the specific heats of magnetic metals (Pionchon, Abstr., 1887, 201) can be quantitatively explained as due to variations in the magnetic energy content.

Assuming each molecule to be a magnet producing lines of force, the energy of complete demagnetisation of iron is calculated to be 16·8 cal. per gram at 20°, becoming less as the temperature rises, and finally disappearing at 753°, at which temperature the iron loses its magnetic properties. The energy of demagnetisation of nickel varies
from 4·3 cal. at 22° to zero at 376°, whilst the corresponding values for magnetite are 14·4 cal. at 15·2° and zero at 588°.

At the ordinary temperature the magnetic phenomena should account for one-twentieth of the specific heat of iron, whilst in the neighbourhood of 753° the proportion would be as much as 43%. Thus the specific heat of iron undergoes an abrupt diminution at 753°.

Calorimetric measurements of the specific heat of iron, nickel, and magnetite over a wide range of temperatures show striking agreement with the results calculated from the magnetic properties. The specific heat of iron alters by 0·112 at 758°, whereas the figures calculated from the magnetic properties are 0·136 at 753°. Values for nickel and magnetite are in still better agreement with the theory.

R. J. C.

The Solid State. W. A. Kurbatoff (J. Chim. Phys., 1908, 6, 337—354).—The melting points and equal fractions of the absolute melting points are to be regarded as corresponding temperatures for solids. It is shown by an examination of the available experimental data that at such temperatures the electrical conductivities, divided by the conductivities at the melting points, are equal for different metals, and that both electrical and thermal conductivity are periodic functions of the atomic weight. At corresponding temperatures, the law of Dulong and Petit holds rigorously, even for boron, carbon, and silicon. The evidence indicates that the molecules of solid metals are monatomic, those of solid non-metals being more complex. The molecules of sulphides, oxides, and other compounds with metallic lustre are non-associated.

C. H. D.

The Heat-contents of Binary Systems. Gustav Tammann (Zeitsch. physikal. Chem., 1908, 63, 129—140).—The thermal equilibrium of binary mixtures may be represented advantageously by means of a three-dimensional model. The ordinary temperature-concentration diagram is used as the base of the model, and perpendiculars are then erected, the heights of which are proportional to the heat-content of unit mass, the upper surfaces then being constructed by means of these perpendiculars. Sections perpendicular to the concentration axis give the variation of heat-content with temperature for a given composition. Photographs of a number of such models, with the corresponding temperature-concentration diagrams, are given for each of the cases discussed by Roozeboom.

In order to construct the model, cooling curves of the mixtures must be taken under similar cooling conditions, and the duration of each arrest determined, as in Tammann’s method of thermal analysis (Abstr., 1904, 113).

C. H. D.

Correction of the Ideal Melting-point Curves of Binary Alloys. Domenico Mazzotto (Nuovo Cim., 1908, 15, 401—422).—The author applies two corrections to the ideal melting-point curve, one depending on the heat of mixture, and the other on the association of the dissolved metal. The data for the former correction are obtained from the author’s determinations (Rend. R. Ist. Lombardo,
1888, [iia], 18, 165), and those for the latter from the atomic depressions measured by Heycock and Neville (Trans., 1889, 55, 666; 1890, 57, 376, 656, 1892, 61, 888; 1894, 65, 31; 1897, 71, 383; Abstr., 1897, ii, 245). The application of these corrections to the melting points of alloys of bismuth and tin, lead and tin, and lead and bismuth, gives curves approximating very closely to the ideal curves. The method fails when the two components form a solid solution, as in the case of tin dissolved in zinc, or when chemical combination takes place, as in lead amalgams. The following coefficients of polymerisation were determined: Bi in Sn, 1·25; Bi in Pb, 2·2; Sn in Pb, 3·8; Zn in Sn, 1·15.

C. H. D.

A Cryoscope. M. C. Dekhuyzen (Biochem. Zeitsch., 1908, 11, 345—381).—The true freezing point of a solution can be expressed by the equation \( t_w = t_s + k_a/K_e(t_s - t_c) \), where \( t_w \) is the true freezing point, \( t_s \) the apparent (actually read) freezing point, and \( t_c \) the “convergence temperature,” that is, the temperature which the solution will attain when congelation does not take place. \( k_a \) is a constant depending on the rate at which the equilibrium of temperature between the freezing vessel and cooling bath is attained. \( K_e \) is a number, by means of which the rate can be calculated at which the ice in the supercooled liquid is formed or dissolved. The above formula is due to Nernst and Abegg. The constant \( k_a \) can be directly determined, the equation \(-\frac{dt}{dz} = k_a(t - t_c)\), where \( z \) represents time, denoting the rate of temperature change of the liquid. From this equation,

\[ k_a = \frac{1}{(t_0 - z_1)\log\text{nat.}(t_1 - t_c)/(t_2 - t_c)}, \]

where \( t_c \) represents the temperature of the cooling mixture. To determine \( K_e \), the following formula was evolved:

\[ \frac{dt}{dz} = K_e(t_w - t_s) - k_a(t_s - t_c). \]

A practically constant cooling bath can be obtained by applying the principles that ice and salt solution attain temperature equilibrium with very small velocity if the surface of the ice and the stirring of the liquid be reduced to the lowest possible limits.

The apparatus employed consists of an inner cooling vessel with ground flange, fitted into a somewhat large cooling vessel, also with ground flange; the two ground surfaces are clamped together. This is covered with an ebonite plate, into which fit two tubes, one of which contains mercury, for quick cooling, and the other tube is a Dewar vessel, formed from two concentric test-tubes with an evacuated space between. A special arrangement made for transferring the vessel containing the liquid under investigation (with the Beckmann thermometer) from the quick-cooling to the Dewar tube is described, and also the methods for determining the values of \( k_a \) and \( K_e \).

S. B. S.

aqueous solutions of a number of electrolytes. The conductivity measurements were made at $0^\circ$ and $99.4^\circ$.

In general, the rise of the boiling point produced by one gram equivalent has a minimum value at a concentration of $0.5$ to $1.0$ gram equivalent per litre. For higher concentrations than that corresponding with this minimum, the rate of increase of the equivalent boiling-point elevation gradually diminishes, and in certain cases a maximum can be observed.

From a comparison of curves which represent the variation of $\mu_e/\mu_\infty$ with the concentration of the dissolved electrolyte, the conclusion is drawn that the degree of ionisation is greater at $0^\circ$ than at $100^\circ$ in the case of dilute solutions, whereas concentrated solutions are more dissociated at the higher temperature.

Assuming that the ionisation can be obtained from conductivity data, and that the elevation of the boiling point (or depression of the freezing point) produced by a gram molecule or gram ion is independent of the concentration of the solution, the experimental data are used to calculate the degree of hydration of the dissolved electrolyte on the assumptions (1) that molecules and ions are hydrated; (2) that the ions only are hydrated, and (3) that the undissociated molecules only are hydrated. The fact that the values obtained on the first assumption are in some cases constant for a series of concentrations is regarded as evidence of hydration of both the undissociated molecules and the ions. For other electrolytes, hydration of the molecules or of the ions alone is assumed.

H. M. D.

Theoretical Determination of the Vapour Pressure of Solid and Liquid Carbon Dioxide. E. Falck (Physikal. Zeitsch., 1908, 9, 433—437).—The validity of Nernst's thermodynamic formula for the variation of vapour pressure with temperature has been examined for liquid carbon dioxide between $-10^\circ$ and $-60^\circ$ and for the solid between $-60^\circ$ and $-154^\circ$. The agreement between the calculated and experimental values is very good, except in the neighbourhood of $-100^\circ$ to $-130^\circ$. A similar deviation for an intermediate range of temperature was found by Naumann in the case of iodine.

The molecular heats of liquid and solid carbon dioxide are given by the formulae $C_l = 3.8 + 0.077T$ and $C_s = 3.8 + 0.032T$ respectively. At all temperatures above absolute zero, liquid carbon dioxide has therefore the greater specific heat.

The free energy and the heat change for the passage of solid carbon dioxide into the liquid form at various temperatures are calculated. The curves representing these values are symmetrical and tangential to a straight line parallel to the axis of temperature.

H. M. D.

Mutual Action of Dissolved Substances as Deduced from their Vapour Pressures. Adam Wroczynski (J. Chem. Phys., 1908, 6, 500—504).—Remarks on Konowaloff's recent papers (Abstr., 1907, ii, 334, 602). It is shown that several of Konowaloff's formulae can be deduced from the general Duhem-Margules formula for the vapour pressures of binary mixtures with the help of Raoult's law. It follows that, contrary to Konowaloff's view, there is no proof of
chemical combination under the conditions of experiment in many of
the binary mixtures studied by that author.

G. S.

**Vaporisation I.** Hanns von Jüptner (Zeitsch. physikal. Chem.,
1908, 63, 355—366. Compare Abstr., 1906, ii, 522 ; 1907, ii, 742).—
The values of \( f \) calculated by the empirical equation
\( \Delta f = \rho_0 - \rho_0 + b/(1 - \theta) \) (see loc. cit.) are in the neighbour-
hood of the critical temperature greater than those derived directly from observation. The
author now shows that when the third term on the right-hand side of
the foregoing formula is multiplied by the factor \( 1 - \theta/\rho(1 - \theta) + 1 \),
where \( \rho \) is a constant, a better agreement is secured, as shown by
figures for fluorobenzene, carbon dioxide, and ammonia.

By combining this modified equation with the Clapeyon-Clausius
formula, an expression is obtained for the latent heat of vapori-
sation.

According to Mathias, \( (D_v + D_o)/2D_b = 2 - \theta \), where \( D_l \) and \( D_v \) are
the densities of liquid and saturated vapour respectively, and \( D_b \)
is the critical density. The agreement between the experimental
figures and the values calculated by this formula is in general very
good, but, according to the author, the expression \( 1 + a'(1 - \theta) \) on
the right-hand side, where \( a' \) is a constant for each substance,
gives even better results, as shown by figures for fluorobenzene
and ammonia. A formula is also developed for calculating the
difference between the densities of liquid and saturated vapour, and
is tested with satisfactory results by the available data for fluoro-
benzene and ammonia. Formulae are further deduced for calculating the
densities and volumes of liquid and saturated vapour in terms of \( \theta \)
and the various constants quoted above.

**Sources of Error in the Ebulloscopic Method and Attempts
to Remove Them.** Ernst Beckmann [With Otto Liesche and
Theodor Klopper] (Zeitsch. physikal. Chem., 1908, 63, 177—215).—
An elaborate series of experiments has been made to determine the
sources of possible error in ebulloscopic determinations. The influence
of the external temperature is discussed, and is shown to be least for
concentrated solutions; it is less than in the case of cryoscopic ex-
periments. Direct electrical heating by means of a thin platinum
spiral is very suitable for non-electrolytes, especially when the boiling
point of the solvent is high. Electrolytes give abnormal results, even
when an alternating current of high frequency is employed.

A method is described by which satisfactory measurements can be
obtained with the bulb of the thermometer immersed only in vapour.
The device employed keeps the bulb of the thermometer free from
liquid, a layer of boiling liquid forming a jacket round the vapour
space. In another form of apparatus, the bulb is immersed in liquid
free from vapour, jacketed with the vapour from the same solution.

The influence of the nature and quantity of filling material (garnets
or platinum tetrahedra) is also discussed.

T. aniline ture benzoic dissolution acetate yellow and benzoate 0.08 temperature acetic rend., benzoate which (if/8 volumes neutralisation rend., Aniline rubber the the benzene acids and base wears-and-tear fuse-thread, wear-and-tear can be introduced after weighing without disturbing the pastille.

Heat of Neutralisation of Acetic and Benzoic Acids by Aniline in Benzene Solution. Léo Vignon and Évieux (Compt. rend., 1908, 146, 1316—1318).—The molecular heats of dissolution of acetic acid, benzoic acid, and aniline, in benzene at M/4 dilution are \(-0.51\) Cal., \(-3.54\) Cal., and \(-1.09\) Cal. respectively. When equal volumes of M/4 solutions of acetic acid and aniline are mixed, a fall of temperature (0.054°) is observed corresponding with an absorption of \(-0.16\) Cal. per molecule. On the other hand, the formation of aniline acetate directly from the acid and base results in the development of heat, whilst the heat of dissolution of aniline acetate in benzene (M/8 dilution) is \(-3.63\) Cal., from which the value +1.87 Cal. is deduced for the molecular heat of combination of acetic acid and aniline.

Similarly, by mixing equal volumes (200 c.c.) of M/4 solution of benzoic acid and aniline in benzene, a very slight elevation in temperature (0.024°) is produced, corresponding with a development of 0.08 Cal. per molecule. Aniline benzoate, however, has a heat of dissolution of \(-9.4\) Cal. at M/8 dilution in benzene, giving the value +4.77 Cal. for the heat of formation.

Determinations of the molecular weights of aniline acetate and benzoate by the cryoscopic method give the values 111 and 151—153, which more nearly agree with those calculated for mixtures of the acid and base than for the salts.

The conclusions are drawn that aniline does not combine with acetic and benzoic acids in benzene solution, and that aniline acetate and benzoate are dissociated by dissolution in benzene.

Heat of Neutralisation of Picric Acid by Different Aromatic Bases in Benzene Solution. Léo Vignon and Évieux (Compt. rend., 1908, 147, 67—69).—Picric acid differs from benzoic and acetic acids (preceding abstract) in that it combines with aromatic bases in benzene solution.

The molecular heat of dissolution of picric acid in benzene at 20° and M/8 dilution is \(-3.8\) Cal. The following are the heats of neutralisation of picric acid by various bases, and the characters of the salts formed. By aniline, +14.75 Cal.; aniline picrate forms small, yellow crystals, of which 100 parts of water dissolve 0.54 part and 100 parts of benzene 0.078 part at 22°. \(\alpha\)-Toluidine, +16.45 Cal.;
o-toluidine picrate is precipitated as orange-yellow flocks, which quickly change into yellowish-white crystals. m-Toluidine, +15.98 Cal.; p-toluidine, +18.15 Cal.; m- and p-toluidine picrates form clear, yellow crystals. Methylaniline, +11.07 Cal. (solid salt); methylaniline picrate forms a golden-yellow, crystalline powder, m. p. 134°. Dimethyl-aniline, +14.1 Cal. (solid salt); dimethylaniline picrate is a granular, yellow powder, m. p. 142°. Ethylaniline, +12.6 Cal. (solid salt); ethylaniline picrate forms a clear yellow, crystalline powder, m. p. 132°. Dimethyl-o-toluidine, +9.45 Cal. (salt dissolved); the golden-yellow solution, after twenty-four hours' standing, deposits clear yellow crystals of dimethyl-o-toluidine picrate, m. p. 116—117°, of which 100 parts of benzene at 25° dissolve 1.35 parts. Phenylhydrazine, +19.03 Cal. (solid salt); phenylhydrazine picrate forms a bright yellow powder, m. p. 148—149°.

The molecular heat of dissolution of o-nitroaniline at 22° and M/8 dilution is -5.51 Cal., and its heat of neutralisation by picric acid is -0.35 Cal. The heat of dissolution of o-nitroaniline picrate, a brick-red, crystalline powder, in benzene at 22° and M/16 dilution is -8.40 Cal., whence the heat of formation in benzene solution is -1.2 Cal. A cryoscopic determination of the molecular weight in benzene solution also shows that no combination has taken place.

These results are an example of salt formation without ionisation. The electrical conductivity of the solutions either before, during, or after admixture is inappreciable.

Benzene solutions of phenol, nitrobenzene, and m-dinitrobenzene do not react with a benzene solution of p-toluidine.

The conclusions are drawn that (1) salt-formation in benzene differs from that in water, (2) that benzene having no appreciable ionising power is particularly useful for the thermal study of the formation of certain salts, (3) that the presence of several nitro-groups in the benzene nucleus greatly intensifies the acidic power of the hydroxyl group, and (4) that the acidity of picric acid becomes zero towards certain bases, such as o-nitroaniline.

Other acids, such as trichloroacetic acid, in which the acidic character is intensified by the presence of the three chlorine atoms, behave similarly to picric acid.

—Lactose can be crystallised from solution in two forms, the monohydrate and the β-anhydrous modification. When the hydrate is heated at 125°, it is converted into the α-anhydrous form. Hudson (Abstr., 1904, i, 974) has determined the rate at which equilibrium is established between the hydrate and the β-modification, and the proportions of the two forms finally present. A study has now been made of the heats of solution of the three forms of lactose, keeping in view the fact that the solution of any one form is complicated by a second heat effect due to the change into the stable mixture of hydrate and β-form. The following terms are employed: The "initial heat of solution" is the heat produced when any form of the sugar is dissolved under such conditions that the change into the
mixture of hydrate and $\beta$-form is greatly retarded. The "final heat of solution" is the total heat developed when any form of the sugar dissolves to yield a solution containing the stable mixture. The "heat of passage" of one form into the other is the heat produced when a given quantity of one form changes in solution into an equivalent quantity of the other. The final heat of solution is thus the sum of the initial heat of solution and the heat of passage. The following results have been obtained by means of calorimetric measurements.

The initial heats of solution in gram-calories are: hydrate, $-12.0$; $a$-form, $+7.3$; $\beta$-form, $-2.3$. The final heats of solution are: hydrate, $-11.4$; $a$-form, $+7.9$; $\beta$-form, $-2.7$. The heats of passage to the $\beta$-form are: hydrate, $+1.0$; $a$-form, $+1.0$. The equality of the heats of passage of the hydrate and the $a$-form support the view that in solution the $a$-form instantly changes into the hydrate, which is then slowly converted into the $\beta$-form. The initial heat of solution of the hydrate increases about 0.1 gram-cal. per degree rise in temperature. On diluting strong lactose solutions (0.5 molal), a slight development of heat occurs, but the heat of solution is independent of the concentration when this is less than about 0.3 molal. The pure $\beta$-form has been prepared, and has $D_{20}^{\circ} 1.59$, whilst the hydrate has $D_{20}^{\circ} 1.54$. The thermochemical data now obtained show that the crystalline substance precipitated from aqueous solutions of lactose by alcohol and ether is a mixture of the hydrate and $\beta$-modification, the two forms being present in approximately the same proportions in which they occur in stable solutions. Observations of the rotatory power of stable solutions of the sugar indicate that the hydration is slightly increased with rise of temperature from 0° to 100°. The final heat of solution of the hydrate, calculated from the solubilities at 15° and 25°, is $-11.5$, which agrees closely with the calorimetric determination at 20°.

New Instrument for Reducing Gas Volumes to Standard Conditions. Grant T. Davis (J. Amer. Chem. Soc., 1908, 30, 971—973).—An apparatus is described for so adjusting the pressure on a gas that its volume is reduced to that which it would occupy under standard conditions of temperature and pressure, calculation being thus avoided. The pressure is applied by means of a column of water, and the method is therefore only suitable for gases which can be collected over water. For details, the description and diagram in the original must be consulted.

E. G.

Orthobaric Densities of Homologous Liquids. G. Ter-Gazarian (J. Chim. Phys., 1908, 6, 492—499).—From the author’s determinations of the densities and critical temperatures of acetonitrile and propionitrile, and from the corresponding determinations of Young for pentane, isopentane, hexane, heptane, and octane, it is shown that the difference between the temperatures of equal densities for two homologous liquids is equal to the difference of the critical temperatures of the same liquids. Hence, if the density curve (liquid) and the critical temperature of a single member of the
The Unit-Stere Theory: Demonstration of a Natural Relation between the Volumes of the Atoms in Compounds under Corresponding Conditions and that of Combined Hydrogen. II. Gervaise le Bas (Phil. Mag., 1908, [vi], 16, 60—92. Compare Abstr., 1907, ii, 754).—The volume relationships of carbon and hydrogen in the liquid hydrocarbons of the olefine and acetylene series, and in aromatic and hydroaromatic compounds, have been examined in the light of the theory put forward in the earlier paper on the basis of data for the liquid normal paraffins.

At the melting point and at temperatures equally removed therefrom, the molecular volumes of the olefines may be represented by the expression: molecular volume \( C_nH_{2n} = 6nS - 2\cdot62 = W'S - (\equiv) \).

Similarly, the molecular volumes of the acetylenes are given by:

\[
\text{molecular volume } C_nH_{2n-2} = 6nS - 2S - 3 = W'S - (\equiv). \]

In these expressions, \( S \) is the value of the unit-stere = 2·97, \( W \) is the total number of valencies of the atoms in the hydrocarbon molecules, and the bracketed symbols represent the volume values corresponding with the unsaturated linkages.

At the boiling point, the molecular volumes of the olefines and acetylenes are given by the formulæ: molecular volume \( C_nH_{2n} = 6nS \) and molecular volume \( C_nH_{2n-2} = 6nS - 2S \) respectively. The value of \( S \) is approximately 3·7, but appears to vary slightly from one compound to another.

The data for aromatic compounds indicate that the atomic volumes in the nuclei are always less than the volumes of the same atoms in straight-chain molecules. The relative volumes of atoms are, however, the same in both cases. The atoms in aliphatic side-chains of aromatic compounds have the same volume as in the paraffins.

In the case of benzene and its homologues, it is shown that the critical coefficients are also subject to the valency law. H. M. D.

Torsional Elasticity of Liquids. L. Lauer and Gustav Tammann (Zeitsch. physikal. Chem., 1908, 63, 141—150).—An apparatus is described by means of which a known torque of short duration could be applied to a glass sphere immersed in the liquid to be examined. The duration of the impulse varied from 0·00000163 to 0·01956 second, and was regulated and measured by means of a Helmholtz pendulum. In other experiments, a steel rod of elliptical section was substituted for the glass sphere.

The liquids investigated were water, glycerol, and undercooled betol containing 1·5% sucrose. The last two gave positive indications of torsional elasticity, increasing with falling temperature. The temperature at which elasticity becomes marked is independent of the duration of the impulse, and almost independent of the moment of torsion. This

—Morgan and Stevenson (this vol., ii, 356) have shown that the weight of a drop of liquid falling from the properly cut end of a glass capillary tube is proportional to the surface tension of the liquid, and can be employed for calculating the molecular weight and critical temperature.

In the present paper, an account is given of experiments which have been carried out with a bevelled tip similar to that used by Morgan and Stevenson, but attached to a burette of smaller diameter than that previously employed. The drop weights of carbon tetrachloride and the liquids studied in the earlier work have been determined at or near the temperatures at which their surface tensions have been measured by the rise of the liquids in a capillary tube. The results are tabulated. They confirm those obtained previously, and show that, for the determination of relative surface tensions, the drop-weight method is more accurate than the ordinary method depending on capillary rise, and, also, that the molecular coefficient of drop weight is a true constant. The drop-weight method is therefore the most accurate available for the determination of molecular weights, except that for permanent gases, which is based on the density. It is also shown that critical temperatures can be more readily and accurately calculated from drop weights than from capillary rise.

E. G.

New Formulæ Correlating the Various Constants for Non-associated Liquids. Eric Higgins (J. Amer. Chem. Soc., 1908, 30, 1069—1074).—Morgan and Stevenson (this vol., ii, 356) and Morgan and Higgins (preceding abstract) have described a method of determining the volumes (and hence the weights) of drops of non-associated liquids delivered from the specially cut end of a capillary tube.

Since the drop volume is proportional to the surface tension, it is shown that $\nu M/T = K$, where $M$ is the molecular weight of the substance in the liquid state, $\nu$ the drop volume, and $T$ the absolute temperature of the b. p. By means of these drop-volume constants of certain non-associated liquids (benzene, pyridine, chlorobenzene, aniline, and quinoline), the following can be calculated from a knowledge of the b. p., molecular weight, and density: the surface tension, critical temperature and pressure, vapour pressure at any temperature, latent heat of evaporation, and the value of $a$ and $b$ in van der Waals' equation. It is also shown that the drop weight and b. p. of a liquid enable its molecular weight to be ascertained, and hence all the constants already enumerated can be calculated.

E. G.

—In earlier papers (Abstr., 1907, ii, 744; this vol., ii, 464), it has
been suggested that the cations of an electrolyte lower the viscosity of a solvent, whilst the anions and non-ionised molecules increase it. It has been considered desirable to test this hypothesis by working with non-aqueous solutions in which the degree of ionisation is less than in water. For this purpose, a study has been made of solutions of potassium iodide in methyl and ethyl alcohols, ethylene glycol, glycerol, furfuraldehyde, acetone, and pyridine. The density of the solutions at 25°/4°, the absolute viscosity, and the ratio of the absolute viscosity of the solutions to that of the solvents are recorded.

The results show that all the solutions, except that in glycerol, exhibit positive viscosity. The negative viscosity of the glycerol solution is attributed to the association of the solvent. The value of the ratio of absolute viscosity to molecular volume has been calculated for fifty non-associated organic liquids, and found to be approximately constant for members of the same class of compounds in the same series. From this ratio, it is inferred that the degree of association of glycerol exceeds that of water. The conclusion that the cation of the electrolyte and the association of the solvent determine negative viscosity is confirmed.

E. G.

Critical Opalescence. Victor Rothmund (Zeitsch. physikal. Chem., 1908, 63, 54—52. Compare Abstr., 1898, ii, 503; also Friedländer, Abstr., 1901, ii, 643).—Mixtures of n-butyric acid and water, for a short interval above the critical solution temperature, exhibit a peculiar bluish opalescence or turbidity. This opalescence is very markedly diminished by dextrose, as well as by a number of salts, but is increased by naphthalene.

The temperature-coefficients of viscosity of these ternary mixtures about the critical solution temperature have been determined, and it is found that in this respect there is no essential difference between dextrose and the salts, on the one hand, and naphthalene, on the other. The influence of these substances on the critical opalescence must therefore be optical in its nature.

According to Donnan (Chem. News, 1904, 90, 139), the interfacial tension at temperatures slightly above the critical solution temperature is still positive for very small radii of curvature, but negative for all ordinary curvatures. If this is so, then the critical opalescence is due to the presence of very fine drops, and a mixture may be really non-homogeneous above the critical solution temperature. The author accepts this explanation, and suggests that the influence of a third substance in diminishing or increasing the opalescence observed in mixtures of n-butyric acid and water is due to an alteration of the refractive index of one of the phases. The nearer the refractive indices of the two phases the more difficult will it be to detect the opalescence, and any substance which brings the index of the one phase nearer to that of the other will apparently diminish the opalescence.

J. C. P.

Cause of the Decoloration of Coloured Liquids by means of Various Charcoals. Fritz Glassner and Wilhelm Suida (Annalen, 1908, 361, 353—362).—It was shown previously (Abstr., 1907, ii,
932) that lampblack, although free from nitrogen and ash, decolorises certain, especially basic, dyes. As this is not in agreement with the behaviour of charcoals in general, the authors have further studied the decolorising action of two specimens of lampblack and one of acetylene-black, all of which were free from nitrogen and ash, and were in a state of fine division.

When boiled with water, lampblack has an odour of camphor; the evaporation residue, as also that from the alcoholic extract, does not absorb dyes. The benzene extract, on the other hand, contains an oil, which has a terpene- or camphor-like odour, and is partly volatile with steam; the evaporation residue absorbs basic dyes from aqueous solutions. The lampblacks differ from animal charcoals in that absorbed dyes are readily dissolved by dilute acids, alkalis, or alcohol, although not by water. As it was observed that the amount of dye absorbed by a lampblack varies with its percentage of oxygen, experiments were performed with a large number of phenols, carboxylic acids, and sulphonic acids, and it was found that these have mostly a high absorptive power for basic dyes. Moreover, it is found that aurine, rosolic acid, and hematoxylin form insoluble compounds with acid dyes. It is suggested that, whilst the absorptive power of animal charcoals results from the presence of substances containing the group N·C·N, that of the lampblacks depends on the presence of oxygen compounds, which form phenolic salts with basic, and oxonium salts with acid, dyes. The authors reply to criticisms by Rosenthaler (this vol., ii, 158).

Diffusion of Albumin into Gelatin Jellies. G. Möllhausen (Zeitsch. Chem. Ind. Kolloide, 1908, 2, 325).—When dry egg- or blood-albumin is placed on the top of a column of solidified gelatin solution containing 2—10% gelatin, the albumin forces its way into the jelly. After some days, a crack appears in the jelly, and this gradually increases in length. Rise of temperature favours the phenomenon. The albumin abstracts large quantities of water from the jelly during the diffusion process.

Addition of phenol to the albumin or jelly has no influence on the phenomenon. It also takes place when the albumin is dissolved previously in an equal weight of water, and when the jelly contains 10% of albumin. Diffusion of the mineral constituents and of the yellow colouring matter of the albumin into the jelly precedes the formation of the crack. The phenomenon cannot be ascribed to a tanning action.

Osmotic Pressure of Compressible Solutions of any Degree of Concentration. Part II. Cases in which both Solvent and Solute are Volatile. Alfred W. Porter (Proc. Roy. Soc., 1908, 80, A, 457—465. Compare Abstr., 1907, ii, 743).—The theory previously developed connecting osmotic pressure with vapour pressure in compressible solutions under any hydrostatic pressure is extended to the general case where the solute, as well as the solvent, has an appreciable vapour pressure. By means of a thermodynamic cycle, it is shown that the variation of vapour pressure of the solvent, and
also of the osmotic pressure, with variation of the hydrostatic pressure is expressed by the same equations as in the case where the solute is non-volatile. A simple proof is given that the vapour pressure of a pure liquid increases with hydrostatic pressure, by assuming that membranes can exist permeable to vapour, but not to liquid molecules. This proof cannot be extended to solutions, because a space variation of concentration would be set up by gravity under the conditions of the proof. The increased vapour pressure at a curved surface (Kelvin’s formula), and also at an electrified surface, is supposed to originate in the higher hydrostatic pressure. R. J. C.

Osmotic Pressure of Sucrose Solutions at 10°. Harmon N. Morse and H. V. Morse (Amer. Chem. J., 1908, 39, 667—680).—In view of the fact that the osmotic pressures of sucrose and dextrose solutions at 0° are somewhat in excess of the calculated gas pressures, whereas at 20° the two pressures are in agreement, it was considered desirable to determine the pressures of such solutions at several intermediate temperatures. The results of measurements of the osmotic pressure of sucrose solutions at 5° have already been recorded (Abstr., 1907, ii, 744), and in the present paper an account is given of determinations made at 10°.

It is found that the osmotic pressure of sucrose solutions at 10°, like those at 0° and 5°, considerably exceeds the calculated gas pressure; it diminishes slightly from the 0·1N to the 0·4N solution, and then increases with increasing concentration. On comparing the pressures at 0° and 10°, some indications of a temperature-coefficient are observable, and this fact will be alluded to again when the results obtained at 15° are recorded.

E. G.

Arguments are first adduced to show how osmotic and other properties of solutions may be explained quantitatively as the result of differences in vapour pressure. An equation is obtained connecting vapour pressure with hydrostatic pressure, according to which a hydrostatic pressure of 2000 atmospheres is necessary to increase the vapour pressure of water four-fold at 27° if its compressibility remains constant.

Consideration of the hypothetical vapour sieve apparatus of Poynting (Phil. Mag., 1881, [v], 12, 40) leads to the result that if a solution and the pure solvent, each contained in a vapour sieve tube, are in equilibrium with the same vapour column, they are in equilibrium with one another. The solution is necessarily under greater hydrostatic pressure than the pure solvent in this case. No disturbance will ensue if the solution sieve be actually surrounded by the solvent column, that is to say, the liquids are in osmotic equilibrium also.

A semi-permeable membrane may therefore be considered as a vapour sieve, and osmotic pressure may be defined as the hydrostatic pressure which must be applied to increase the vapour pressure of a solution to
that of the pure solvent. Conversely, liquids in osmotic equilibrium necessarily have the same vapour pressure.

The osmotic pressure of a solution is independent of hydrostatic pressure only if the solvent occupies the same volume in the solution as in the pure state. In a column of solution, the increase in vapour pressure downwards will be the difference between the increase due to hydrostatic pressure and the decrease due to the concentration of the solute by gravity, so that the gravity effect can be evaluated in the case of sucrose solutions from Berkeley and Hartley's vapour pressure measurements.

All the foregoing relationships can be simply established by equating to zero the work done in taking unit mass of solvent round a closed "osmotic circuit," and the author prefers this method to the isothermal cycle method employed by Porter (Abstr., 1907, ii, 743). An equation is obtained connecting hydrostatic pressure with latent heat of vaporisation, from which it appears that a pressure of 42 atmospheres would increase the latent heat of water by 1 cal.

The author's theory of solutions is based upon the hypothesis that the vapour pressure of a solution should be proportional to the ratio of the number of molecules of free solvent to the total number of molecules in the solution, molecular aggregates and hydrates being considered as single molecules. Thus if in a solution of \(n\) molecules of solute in \(N\) molecules of solvent each molecule of solute appropriates \(a\) molecules of solvent, the number of free molecules of solvent will be \((N - an)\), and the total number of molecules will be \((N - an + n)\). If \(p'\) and \(p''\) be the vapour pressure of solvent and solution, \(p''/p' = (N - an)/(N - an + n)\). If sucrose be considered to hold 5 molecules of water of hydration, and if dextrose holds 2 molecules, this equation gives results which agree with Berkeley and Hartley's determinations of the osmotic pressure of these two substances within the limits of experimental error. The calculation must be made on a weight normal basis, and the hydration considered to be constant over the whole range of dilutions.

It is pointed out that the latent heat of fusion of ice has not the same value at temperatures below the freezing point as at 0°, and that the "molecular lowering" of the freezing point of water by a dissolved substance, which depends on the latent heat of fusion of the solvent, must also vary with the temperature; furthermore, the freezing-point lowering is generally tacitly assumed to be directly proportional to the ratio of the difference of vapour pressures of ice and water to the vapour pressure of water. Therefore the author considers that the usual method of comparing the found with the calculated freezing-point depressions is futile in the case of strong solutions with a freezing point far removed from 0°.

Owing to the uncertainty of existing data for the vapour pressure of water below 0°, an exact formula connecting the vapour pressures of water and ice is not possible. A number of possible formulae are obtained by considering an "osmotic circuit," and the author finally adopts as the best approximation the simple expression

\[ \log_e(p'/p) = -2.64t/273, \]

where \(p'\) and \(p\) are the vapour pressures of water and ice respectively, at \(t\)° Centigrade. On this basis, the
freezing-point depressions of sucrose solutions agree very well with the calculated values when the hydration \( (a) \) is taken as 5. The depressions of methyl- and ethyl-alcohol solutions containing upwards of 20 mols. per 100 of solvent agree very well with the theoretical when the hydration is taken as 1. Glycerol appears to have hydration 2, but the freezing-point diagrams of acetone and formic acid lie very near the curve plotted with \( a = -1 \), which suggests that the molecules of these substances associate with each other.

The application of the theory to electrolytes is complicated by questions of electrolytic dissociation. Assuming the number of free ions to be proportional to the conductivity, the following hydrate values are deduced from freezing-point data: \( \text{HCl,5H}_2\text{O} \); \( \text{CaCl}_2,5\text{H}_2\text{O} \); \( \text{MgCl}_2,12\text{H}_2\text{O} \); \( \text{KCl},\text{H}_2\text{O} \); \( \text{NaCl,2H}_2\text{O} \).

When the rise of the boiling point of solutions is considered from the author’s point of view, sucrose appears to have the same hydration at 100° as at 0° (namely, 5\text{H}_2\text{O}) except in the strongest solutions, where it is somewhat less. Potassium and sodium chlorides, on the other hand, are calculated to be more highly hydrated at 100° (\( \text{KCl,4H}_2\text{O} \); \( \text{NaCl,6H}_2\text{O} \)) than at the freezing point.

On thermodynamic principles, the hydration of a substance cannot remain constant on diluting its solutions unless the heat of dilution is zero, as in the case of sucrose. Consideration of the special case of hydrochloric acid with its great heat of dilution indicates that the variation in hydration is not necessarily very great, particularly as the heat developed on dilution may be partly the result of increased dissociation.

The author claims to have made out a good \textit{prima facie} case for a modified form of the hydrate theory of solutions, and compares his results with those obtained by other advocates of the same hypothesis.

R. J. C.

The Solubility Product. \textbf{Julius Stieglitz (J. Amer. Chem. Soc., 1908, 30, 946—954).—This paper contains a discussion of the principle of the solubility product which was enunciated by Nernst (Abstr., 1890, 3). From the data obtained by Arrhenius (Abstr., 1900, ii, 201) on the solubilities of silver acetate, propionate, butyrate, valerate, and chloroacetate in the presence of an excess of the corresponding sodium salt, the values of the solubility product (\( C_{\text{Ag}} \times C_{\text{acid ion}} \)) have been calculated. The results of Nernst’s determinations (loc. cit.) of the solubility of silver acetate in presence of sodium acetate and silver nitrate respectively have also been re-calculated.

The results show that the solubility product has no theoretical foundation, and is only to be regarded as an approximate empirical principle. In the case of the organic silver salts, the principle is sufficiently in agreement with the observed facts to prove of some practical value, and this conclusion confirms the results obtained by other authors on the solubility of a salt in presence of other electrolytes having a common ion.

Relationships between Chemical Composition, Crystalline Form, Hardness, and Density. \textbf{I. Viktor Pöschl (Zeitsch. anorg. Chem., 1908, 59, 102—107).—The author has found certain}
relationships between the crystalline form, hardness, and density of polymorphic minerals. Of two such polymorphic forms, that which has the greater density and the greater crystalline symmetry is never less hard than the second modification. If the modification of a lower degree of symmetry has the greater density, this form is never less hard than the second form.

The densities of a number of mineral sulphides have been compared with those of the constituent elements. In all cases, the density of the mineral is intermediate between the densities of the elements. The former can be approximately calculated from the latter by means of the simple mixture rule. The calculated densities are, in nearly all cases, somewhat smaller than the experimental values. The deviation between the two values is shown to be a periodic function of the atomic weight of the metal. H. M. D.

Relation between the Crystalline Form and Chemical Constitution of the Picryl Derivatives. George Jerusalem and William J. Pope (Proc. Roy. Soc., 1908, 80, A, 557—566).—The theory of Barlow and Pope as to the relation between crystalline form and chemical constitution (Trans., 1906, 89, 1675; 1907, 91, 1150) has been further tested by application to a number of derivatives containing the 1 : 3 : 5-trinitrophenyl or picryl group.

As regards crystalline structure, benzene and its simple derivatives belong to one of two types: one, derived from the closest-packed assemblage of equal spheres of hexagonal type, has the equivalence parameters $x: y: z = 3:101:3:480:2:780$; the other is derived from the closest-packed assemblages of equal spheres of cubic type. The direction of $z$ is perpendicular to the two planes containing the centres of the two sets of hydrogen atoms ordinarily numbered $1 : 3 : 5$ and $2 : 4 : 6$ respectively. Of the thirteen picryl compounds for which data are now available, it is shown that nine belong to the hexagonal type, and that for these compounds the effect of substitution is to alter two of the dimensions only, the third, of relative length 2:780, corresponding with the $z$ dimension of benzene, remaining practically unaltered.

Among the substances belonging to the rhombohedral arrangement are $s$-trinitrobenzene and picric acid. On passing from $s$-trinitrobenzene to the similarly-constituted tribromodinitrotoluene there is practically no change in the equivalence parameters, corresponding with the fact that the valencies of the groups displaced are the same as those of the original groups. G. S.

Dimorphism of Potassium Calcium Chromate. A. V. Rakowski (Bull. Acad. Sci. St. Petersburg, 1908, 10, 905—917).—The object of the research was to test the question whether two polymorphic forms of a substance can belong to the same crystalline system.

The $\beta$- and $\alpha$-forms of potassium calcium chromate,

$$K_2Ca(CrO_4)_2\cdot 2H_2O,$$

the crystalline characters of which are discussed in detail, are prepared by the action of unslaked lime on potassium dichromate, the quantity of each modification formed depending on the pressure and
temperature at which crystallisation occurs, and on the presence of other substances in the solution.

The α-modification belongs to the rhombic system \([a:b:c = 2:3:629:12:0:0946]\), \(D_{15}^\text{ii} = 2.449\) (2.413 for large crystals), molecular heat of solution 6993 Cal. The β-modification belongs to the hemihedral triclinic system \([a:b:c = 0.7591:1:0.8915\); \(a = 86°10'\); \(β = 94°4'; \gamma = 81°40'\], \(D_{15}^\text{ii} = 2.611\) (2.600 for large crystals), molecular heat of solution 5458.8. Solubility curves and tables are given for both varieties, showing that the solubility of each increases with the temperature, and that the α-modification is unstable with reference to the β-form, the transition-temperature of the former being at about 0°.

At 97° the dry salt decomposes, thus: \(K_2\text{Ca(CrO}_4)_2\cdot 2\text{H}_2\text{O} \rightleftharpoons K_2\text{CrO}_4 + \text{CaCrO}_4 + 2\text{H}_2\text{O}\). A solution saturated at 20° becomes cloudy at 55—60°, and the precipitate formed at 90—100° corresponds with the formula \(K_2\text{CrO}_4 + 4\text{CaCrO}_4 + 2\text{H}_2\text{O}\); at 260°, the water in this salt commences to separate.

Theory of Colloids. Eduard Jordis (Zeitsch. Chem. Ind. Kolloide, 1908, 2, 361—367).—A critical examination of the principles underlying a theory of colloids. In this first portion of the paper, the various possible types of homogeneous mixtures which may be classified under the head of solutions are discussed. A hydrosol regarded as a homogeneous mixture of solid and liquid particles is considered to satisfy the requirements of the definition of a solution.

H. M. D.

Diagrammatic Representation of Equilibria between Acids and Bases in Solution. Lawrence J. Henderson (J. Amer. Chem. Soc., 1908, 30, 954—960).—Diagrams have been constructed which express the requirements of the concentration law regarding the equilibrium in solution between strong acids and bases, and between strong bases and acids, of all strengths, but are not suitable for solutions of high acidity or alkalinity. These diagrams accurately define the conditions of equilibrium at all concentrations of hydrogen and hydroxyl ions, between all acids and bases, with the exceptions already mentioned, and in all mixtures of such substances. They also define all isohydric solutions of such substances in which this quality depends only on the equality of the concentration of hydrogen and hydroxyl ions.

E. G.

Calcium Phosphates. III. The System CaO—P_2O_5—H_2O. Henry Bassett, Jun. (Zeitsch. anorg. Chem., 1908, 59, 1—55. Compare Proc., 1906, 315).—By means of dilatometer experiments, the position of quintuple points on the space model of the three-component system CaO—P_2O_5—H_2O has been determined. At these temperatures
changes take place which, on the basis of solubility measurements, can be formulated by the following equations:

- **36°.** \( \text{CaHPO}_4\cdot 2\text{H}_2\text{O} = 0.9985 \text{ CaHPO}_4 + 0.000384 \text{ Ca}_3(\text{PO}_4)_2\cdot \text{H}_2\text{O} + (2.00036 \text{ H}_2\text{O} + 0.00033 \text{ CaO} + 0.00036 \text{ P}_2\text{O}_5) \)

- **21°.** \( \text{CaHPO}_4, 2\text{H}_2\text{O} + 0.138 \text{ CaH}_4(\text{PO}_4)_2\cdot \text{H}_2\text{O} = 1.0747 \text{ CaHPO}_4 + (2.374 \text{ H}_2\text{O} + 0.10007 \text{ P}_2\text{O}_5 + 0.0627 \text{ CaO}) \)

- **152°.** \( \text{CaH}_4(\text{PO}_4)_2\cdot \text{H}_2\text{O} = 0.495 \cdot 2 \text{ CaH}_4(\text{PO}_4)_2 + 0.427 \text{ CaHPO}_4 + (1.80 \text{ H}_2\text{O} + 0.292 \text{ P}_2\text{O}_5 + 0.078 \text{ CaO}) \)

The formulae in brackets represent the composition of the solutions in equilibrium with the solid phases at the various quintuple points.

As the result of measurements of solubility at 25°, 40°, and 50.7°, isothermals have been obtained, on the basis of which the space model for the three-component system has been constructed.

The observation of van't Hoff, that the velocity with which changes in complicated systems take place diminishes with increasing basicity of the acid radicle and increasing valency of the metal, is confirmed by the author's observations.

The paper concludes with certain speculations as to the nature of the calcium phosphates which have been examined, and as to the condition of the phosphoric acid contained in soils.  

**H. M. D.**

—The three-component system has been examined according to the methods of the phase rule. Data are recorded representing the composition of the aqueous solutions in equilibrium with the various combinations of solid phases. Of the various double salts described in the literature, namely, \( \text{HgCl}_2\cdot \text{NH}_4\text{Cl} \); \( \text{HgCl}_2\cdot \text{NH}_4\text{Cl}, \text{H}_2\text{O} \); \( \text{HgCl}_2\cdot 2\text{NH}_4\text{Cl}, \text{H}_2\text{O} \); \( 9\text{HgCl}_2, 2\text{NH}_4\text{Cl} \), and \( 3\text{HgCl}_2, 2\text{NH}_4\text{Cl}, 4\text{H}_2\text{O} \), the first and last do not exist at 30° according to the author's experiments. These, however, indicate the existence of a double salt of the composition \( 3\text{HgCl}_2, 2\text{NH}_4\text{Cl}, \text{H}_2\text{O} \).

Of the various double chlorides, \( \text{HgCl}_2, 2\text{NH}_4\text{Cl}, \text{H}_2\text{O} \) is the only one which can be recrystallised from its aqueous solution.  

**H. M. D.**

Calculation of Hydrocarbon Equilibria.  

H. VON WARTENBERG (Zeitsch. physikal. Chem., 1908, 63, 269—272).—An error having crept into the calculation of the methane equilibrium in the earlier paper (this vol., ii, 26), this calculation is revised, with the result that the deviation between observed and calculated figures is greater than before. No complete explanation of the discrepancy can be expected until the equilibrium has been subjected to further experimental investigation.  

**J. C. P.**

Statics and Kinetics of the Transition which occurs in Liquid Sulphur.  

Heat of Fusion of Monoclinic Sulphur.  

ALBERT WIGAND (Zeitsch. physikal. Chem., 1908, 63, 273—306).—The heat of fusion of monoclinic sulphur has been determined by an electrical method. A weighed quantity of sulphur was put in a glass
vessel inside an oil calorimeter, which in its turn was surrounded by an electric bath kept at 116°. When it was certain that the sulphur had been completely converted into the monoclinic variety, a known amount of energy was added by passing a current through a wire embedded in the sulphur; the added heat was so adjusted as to melt all the sulphur and to raise the temperature of the calorimeter about 5°, more or less. The value so found for the heat of fusion is 10.4 cal. for 1 gram of sulphur, with a possible error of ± 3%.

From this figure, the molecular depression constant for monoclinic sulphur is calculated by van't Hoff’s formula; if further 42.5° is taken as the depression due to a gram atom of the insoluble variety (see Smith, Abstr., 1903, ii, 139) the number of atoms in a molecule of this insoluble sulphur works out to 6.9. The author, however, considers that 8 is more probably the correct number (see Smith, loc. cit.), and $S_8$ is accordingly taken as representing the molecular condition of both the soluble and the insoluble modifications.

The view that the two molecules have the same number of atoms, and that liquid sulphur is subject to a reversible isomeric change, $S_{8\text{sol}} = S_{8\text{insol}}$, is supported by Schaum's figures, which show how the freezing point of a sample of sulphur falls when it is kept for gradually increasing periods at temperatures above 120°. From these figures, it is possible to calculate satisfactory velocity-coefficients for the foregoing isomeric change, and from the values of the coefficient at different temperatures it is calculated that the heat absorbed when 1 gram of liquid soluble sulphur is transformed into the liquid insoluble modification is 21.1 cal.

From all this, it appears that the transition which occurs in liquid sulphur is an intramolecular rearrangement, which does not involve any change in the molecular weight (compare Smith, loc. cit.). J. C. P.

Affinity Constants of Organic Acids determined with the Help of Indicators. Eduard Salm (Zeitsch. physikal. Chem., 1908, 63, 83—108).—The affinity constants of sixty-eight organic acids have been determined by the indicator method already described (Friedenthal, Abstr., 1904, ii, 288; Salm, Abstr., 1904, ii, 536; 1906, ii, 218. Compare also Veley, Trans., 1907, 153, 1246). Solutions of hydrochloric acid were used as standards of comparison, and the indicators employed were dimethylaminoazobenzene, methyl-orange, and tropæolin-00. In the great majority of cases, the affinity constants deduced in this way are in good agreement with the values reached by the conductivity method. In the case of formic and oxalic acids, the value of the expression $a^2/(1 - a)V$ falls off on dilution. J. C. P.

Saponification of Glycerides during Ester Exchanges in Homogeneous System. Milan J. Stritar and Richard Fanto (J. pr. Chem., 1908, [ii], 78, 35—41. Compare Abstr., 1904, i, 843; 1907, i, 277).—The authors have calculated the results of their experiments on the saponification of rape-seed oil, as suggested by Wegscheider (this vol., ii, 165). If it is assumed that at the moment when the saponification is stopped the product is a mixture of diglyceride and ester, the mean partition coefficient for the second VOL. XCIV. ii.
minute of the experiment is found to be 1.88, whilst that for the third minute is 1.02, hence in the second minute about twice as much glyceride as ester is saponified, whereas in the third minute the amounts are approximately equal. If, on the other hand, it is assumed that, at the moment of stoppage of the saponification, the combined glycerol is present as a mixture of tri- and mono-glycerides, the partition coefficient for the second minute is 2.35, and for the third minute, 1.28. Here, again, the saponification of the glyceride decreases in comparison with that of the ester. These results are in agreement with the authors' views as to the mechanism of the saponification of fats.

The remainder of the paper is a reply to Kremann (this vol., i, 120).

G. Y.

Schütz's Rule for Reaction Velocities. Svante Arrhenius (Meddel. K. Vetensk. Nobelinst., 1908, 1, No. 9, 1—17).—The author discusses a relationship pointed out by Schütz (Abstr., 1885, 1147) in connexion with the rate of action of pepsin on albumin. According to this, the quantity of albumin transformed in a given time by different amounts of pepsin is proportional to the square root of the pepsin concentration, provided that the reaction is not allowed to proceed too long. The same relationship has since been found in the action of trypsin and of lipolytic ferments.

It is shown that for the validity of Schütz's rule, the reaction velocity must be inversely proportional to the quantity of substance already transformed. This condition is fulfilled when one of the reacting substances is influenced by one of the products of reaction in such a way that the active mass of the former is inversely proportional to the active mass of the latter.

An example of such a reaction is afforded by the saponification of an ester present in large excess by a weak base, like ammonia. The reacting component to be considered is the OH' ion, and the active mass of this is determined by the dissociation equation

\[ k[NH_4OH] = [NH_4^+][OH^-]. \]

As saponification proceeds, the concentration of the NH_4^+ ions increases proportionally with the amount of ester saponified, and corresponding with the dissociation equation the concentration of the OH' ions diminishes in inverse proportion.

Measurement of the rate of saponification of ethyl acetate by ammonia, under the conditions specified, has shown that Schütz's rule is valid until about half the ammonia has been transformed. From this point, the deviations between experiment and the requirements of the rule increase very rapidly. The progress of the reaction was followed by determination of the electrical conductivity of the solution.

An action similar to that of an ammonium salt on ammonia is supposed to determine the similar progress of the action of pepsin on albumin. The cause of the action is supposed to be the combination of the reaction product with the ferment.
Review of the Various Theories of Passivity. Fresh Observations on the Passivity of Iron, Nickel, and Chromium. **Carl Fredenhagen** (Zeitsch. physikal. Chem., 1908, 63, 1—47. Compare Abstr., 1903, ii, 353; 1906, ii, 76; also Finkelstein, Abstr., 1902, ii, 81; Müller, Abstr., 1904, ii, 610).—The passivity of metals is supposed by some to be due to the formation of a film of oxide on the surface of the metal, and by others to be due to the change of the metal into another modification. The author rejects both these explanations, and argues in favour of the view, previously upheld by him (*loc. cit.*), that in the passive condition the metal is protected by a surface layer of gas.

The experiments recorded in the paper consisted in applying a gradually increasing or a gradually diminishing *E.M.F.* to an iron, nickel, or chromium electrode immersed in sulphuric acid, and determining (1) the *P.D.* at this electrode, and (2) the strength of the polarisation current. The *P.D.* of the metal electrode at the point where passivity or activity sets in is not well defined, and this supports the view that the passivity phenomena do not depend on the formation either of an oxide film or of another modification of the metal, but that they are ultimately related to the rate at which the metal becomes charged with oxygen. Further, the *P.D.* recorded when passivity or activity sets in is markedly affected by slight changes in the strength of the sulphuric acid, and rise of temperature has a notable influence in favouring the active condition. At an iron electrode immersed in sulphuric acid and subjected to anodic polarisation, some reactions take place which lead to the production of oxygen, and others use up oxygen. According to the author, the passive condition is reached when the oxygen polarisation extends uniformly over the whole surface of the electrode, and the reappearance of the active state on lowering the polarisation *E.M.F.* is due to the fact that the reactions which use up oxygen begin to overbalance those which produce oxygen.

J. C. P.

The Excitation and Regulation of Catalytic Pulsations by means of an Electric Current. **Georg Bredig** and **Ernst Wilke** (Biochem. Zeitsch., 1908, 11, 67—81).—Bredig and Weinmayer have shown that the catalytic decomposition of hydrogen peroxide into water and oxygen, a reaction discovered by Thénard, takes place under certain conditions in rhythmical periods. The influence of electrical currents on this rhythm has been studied. The peroxide solution was placed in a vessel, with mercury at the bottom, into which an electrode passed. The other electrode was placed in the peroxide solution. The apparatus was so arranged that the evolution of oxygen could be graphically recorded. It was found that by means of a constant current, alternating current, or induction shock, an a-periodic chemical change could be converted into a period change. Also, that a spontaneous rhythmical catalysis could be modified as regards its pulsation form, its period, or intensity by means either of a constant or alternating current. The relations of these phenomena to certain biological processes, such as nerve stimulation, are discussed. S. B. S.
Catalysis in Heterogeneous Systems. Decomposition of Chromous Chloride by means of Platinum. Casimir Jabczyński (Bull. Acad. Sci. Cracow, 1908, 398—401).—The decomposition of chromous chloride between platinised platinum plates has been examined. Between 25° and 55° the reaction appears to be unimolecular. When smooth platinum foil is used, the velocity is some three times smaller than with platinised plates. The velocity of decomposition varies with the rate at which the liquid is stirred. The temperature-coefficient, 2.75% per 1°, is the same as for ordinary diffusion experiments, so that the velocity appears to depend entirely on diffusion, and the actual chemical reaction proceeds with enormous velocity. The effect of non-electrolytes, for example, alcohol and sugar, on the velocity is exactly the same as for other diffusion experiments.

The velocity depends on the amount of hydrochloric acid present, and is accelerated by the addition of potassium or calcium chloride, but diminished by the addition of chromic chloride. The reaction does not proceed in the presence of potassium chloride unless free acid is also present.

These phenomena are accounted for by the assumption of the formation of an additive compound of chromous and chromic chlorides, which has a slower rate of diffusion. Addition of hydrochloric acid, potassium chloride, or calcium chloride tends to decompose this compound, liberating chromous chloride, whereas increase in the concentration of the chromous chloride, or addition of chromic chloride, increases the amount of the additive compound.

Iodine and mercuric chloride do not affect the decomposition, whereas small amounts of hydrogen sulphide diminish the rate of decomposition; hydrocyanic acid acts less readily.

J. J. S.

Catalysis. VI. Catalysis of Imino-esters. Hermann I. Schlesinger (Amer. Chem. J., 1908, 39, 719—771. Compare Stieglitz, this vol., ii, 167, 168; Derby, this vol., i, 419).—Measurements have been made of the velocity of hydrolysis of the hydrochlorides of methyl and ethyl iminobenzoates in 1/10 and 1/40 molar solutions, and also of the velocity of decomposition of methyl, ethyl, and n- and iso-propyl iminobenzoates, and of methyl m-nitroiminobenzoate, under the influence of varying proportions of barium hydroxide. A study has also been made of the decomposition of methyl iminobenzoate in aqueous solutions. The results are tabulated, and lead to the conclusions which have already been expressed by Stieglitz (loc. cit.).

E. G.

Potential Energy of the Elements. Daniel J. Rankin (Chem. News, 1908, 97, 302—303).—An element is regarded as a system of energy which under normal conditions exist in two states, static or intrinsic energy and potential energy. The intrinsic energy is incapable of being freed, is inert, and is uninfluenced by any ordinary extraneous energy whatsoever. The potential or free existing energy permits of calculation in terms of thermal calories, and this the author has done for seventy-seven elements. In thermochemical measure-
ments, the "heat of formation" is the value of that portion of the potential which is lost or integrated, and the resulting compound undergoes diminution or increase in volume in a fixed ratio to the loss or gain of potential. For most elements the atomic weights of which are below 60, it has been found that the ratio of loss of potential to loss of volume = 1:1, except in the zinc, cadmium, mercury family, where it is 1:0.76, and with sodium, calcium, and potassium, 1:0.65 nearly. Examples are given showing that it thus becomes possible to calculate the density of a substance, such as solid oxygen or chlorine, when existing in a chemical compound; also, the specific gravity of a chemical compound when the heat of formation is given.

J. V. E.

Deduction of Stoicheiometric Laws. F. WALD (Zeitsch. physikal. Chem., 1908, 63, 307—324).—In replying to de Vries (this vol., ii, 366), the author maintains and extends his earlier views as to the possibility of deducing all quantitative chemical relationships from purely qualitative data. The limitations of the atomic hypothesis and of the theory of valency are emphasised. The author shows that of all the facts to which the name "stoicheiometric" can be applied, the most general is this, that a qualitative analysis is possible without a quantitative.

J. C. P.

Safety Apparatus for Ovens, Baths, &c. LOUIS L. DE KONINCK (Bull. Soc. chim. Belg., 1908, 22, 192—195).—A modified form of H. Michaelis' apparatus (Abstr., 1897, ii, 169) devised to automatically cut off the supply of gas to burners placed under baths, &c., provided with constant supply arrangements for water, in case the water supply is temporarily stopped, is described and figured.

T. A. H.

Simple Arrangement for Continuous Extraction with a Solvent of Inconstant Boiling Point. EMIL WÖRNER (Chem. Zeit., 1908, 32, 608).—When using a Zuntz pattern Soxhlet apparatus for extracting with a solvent of no very definite boiling point, such as light petroleum, a mixture of alcohol and chloroform, &c., it is recommended that a wire spiral be placed round the extraction cup instead of the fragile glass tube. In this manner, the solvent of slightly lower boiling point is prevented from accumulating in the upper region of the tube, and by having intermediate porous layers of sand or wadding the extraction takes place quite rapidly.

J. V. E.

Circulation Stirrer for Liquids. ROBERT GOETZE (Chem. Zentr., 1908, i, 1509—1510; from Zeitsch. Chem. Apparatenkunde, 1908, 3, 147).—A tubular glass stirrer having four short, horizontal open limbs is made to revolve rapidly in a flask-shaped vessel containing the liquid, so that the liquid is forced by the revolving limbs up a side-tube situated exactly opposite them, the action being similar to that of a centrifugal pump. The return liquid enters the vessel through the hollow spindle of the stirrer.

J. V. E.
Inorganic Chemistry.

Decomposition of Water Vapour by Electric Sparks. Alfred Holt, jun., and Edwin Hopkinson (Phil. Mag., 1908, [vi], 16, 92—110).—The authors have examined the decomposition of water vapour and carbon dioxide by electric sparks, and the conclusion is drawn that the separation and distribution of the decomposition products noted by previous observers in the case of water vapour is not an electrical phenomenon, but is the result of gaseous diffusion. The decomposition effects cannot be explained by ordinary electrolysis.

When sparks are passed through water vapour contained in an apparatus of the type used by Chapman and Lidbury (Trans., 1902, 81, 1301), hydrogen and oxygen are produced in the path of the spark. On account of its greater rate of diffusion, the hydrogen tends to become uniformly distributed throughout the apparatus, even when a rapid current of vapour is passing through it. The distribution of the oxygen depends on the relative position of the tube, through which the water vapour enters the sparking vessel, in reference to the anode and cathode. When the water vapour enters at the anode, the greater portion of the oxygen will be swept out at the cathode and vice versa. With the entrance tube near the centre of the spark-gap, equal quantities of oxygen are swept towards the separate poles. This view is supported by experimental data, and it is shown that, under like conditions, the products of decomposition of carbon dioxide, corresponding with their nearly equal rates of diffusion, are always distributed symmetrically.

The observation made by Chapman and Lidbury (loc. cit.) that the total quantity of water vapour decomposed, and the extent of the separation of the hydrogen and oxygen, is much greater when the current of water vapour enters the discharge tube in the neighbourhood of the cathode instead of near the anode is confirmed. To explain this, it is supposed that the metallic spray produced by the disintegration of the cathode exerts a catalytic action, which results in a greatly increased union of the products of dissociation. With aluminium electrodes, which do not yield such a metallic spray, the effect is not observed. Using platinum electrodes, the effect diminishes when thicker wires are used, corresponding with diminished disintegration; it is also smaller when the bulbs surrounding the electrodes are made larger.

The behaviour of other metallic electrodes has also been examined. Metals which oxidise when heated in air behave like aluminium; those which do not oxidise or which form a volatile oxide, as in the case of osmium, behave like platinum. Silver and palladium are exceptions. Although silver sprays readily, it does not appear to have any effect on the union of the dissociation products. The behaviour of platinum is traced to its exceptionally high catalytic activity.

On this view, J. J. Thomson's observation, that the pole at which the excess of hydrogen or oxygen appeared in his experiments depended on the length of the spark, can also be explained.

H. M. D.
Activity of the Halogens, Chlorine, Bromine, and Iodine in Relation to the Metals in General. M. C. Schuyten (Chem. Zeit., 1908, 32, 619—620. Compare this vol., ii, 31).—The chlorides of twenty-four metals have been digested with bromine and with iodine, and the bromides of twenty-three metals digested with iodine. After testing the residues from the metallic chlorides and showing the absence of free halogen, they were treated with chloride water and again tested, when it was generally found that some bromine or iodine was liberated. In the case of the bromides digested with iodine, the dry test for iodine generally indicated the presence of small quantities of that halogen. Whether addition or substitution of halogen takes place under these conditions, the author is at present unable to decide.

J. V. E.

Variation of the Surface Tension of Sulphur with Rise of Temperature: \( \text{SA}^1 \) and \( \text{SA}^2 \). Georges Capelle (Bull. Soc. chim., 1908, [iv], 3, 764—767).—Smith has shown (Abstr., 1905, ii, 382, 580) that between the melting point (125°) and 160° a definite liquid form of sulphur (\( \text{SL} \)) exists, and that at 160° this passes into a new form (\( \text{SL}_2 \)). The author confirms and extends this view from observations on the anomalous change in the surface tension of sulphur as the temperature is raised from 125° to 160°. Between 125° and 142° a slight increase in surface tension takes place, and between 142° and 160° a large and rapid increase. At 160° the liquid becomes viscos, and observations cannot be carried further. It is suggested that Smith’s \( \text{SL} \) is divisible into two species, one (\( \text{SL}^1 \)) existing between 125° and 142°, and the other (\( \text{SL}^2 \)) between 142° and 160°, but \( \text{SL}^2 \) may be merely a mixture of \( \text{SL}^1 \) with \( \text{SL}_2 \), the formation of the latter commencing at 142° and becoming complete at 160°.

T. A. H.

Colloidal Sulphur. M. Raffo (Zeitsch. Chem. Ind. Kolloide, 1908, 2, 358—360).—Soluble colloidal sulphur is obtained when a concentrated solution of sodium thiosulphate is added very slowly to cooled concentrated sulphuric acid (D \( 1.84 \)). If the addition of the thiosulphate solution is effected too rapidly, a large proportion of insoluble sulphur is formed. The changes taking place are represented by the equations:

1. \( \text{H}_2\text{S}_2\text{O}_3 = \text{SO}_2 + \text{H}_2\text{O} + \text{S} \) (insoluble);
2. \( \text{H}_2\text{S}_2\text{O}_3 = \text{H}_2\text{S} + \text{SO}_3 \); \( 2\text{H}_2\text{S} + \text{SO}_2 = 2\text{H}_2\text{O} + 3\text{S} \) (soluble).

In order to separate the soluble and insoluble sulphur, the thick, cloudy liquid is diluted somewhat, heated to 80°, and filtered through glass-wool. It is then left in a cool place for twelve hours, again heated and filtered, and these operations are repeated until the whole of the insoluble sulphur has been removed. The end product is a cloudy, yellowish-white mass, which, on warming, yields a perfectly clear yellow liquid. On cooling, the colloidal sulphur separates, and is removed by centrifuging, washed with a little cold water, again centrifuged, and dissolved in the least possible quantity of water. The liquid is neutralised by addition of sodium carbonate, which causes the sulphur to separate, and, after centrifuging, a residue of very nearly pure soluble sulphur is obtained.

On removing the sodium sulphate from the neutralised solution by
dialysis, it is found that the solution became unstable and insoluble sulphur separates. The conclusion is drawn that a pure aqueous solution of colloidal sulphur cannot be obtained. Separation also takes place on addition of various electrolytes. The sulphur precipitated by sodium chloride or nitrate dissolves on warming or on dilution, and that precipitated by potassium chloride, nitrate, or sulphate is insoluble. Precipitation does not take place, in general, on the addition of ammonium sulphate, nitrate, or chloride, or of sodium sulphate. Dilute unneutralised solutions remain clear for long periods, although small quantities of rhombic and monoclinic sulphur are gradually deposited. Concentrated solutions become cloudy in consequence of the separation of insoluble sulphur.

H. M. D.

Spontaneous Oxidation of Sulphur and Sulphides. Egidio Pollacci (Boll. chim. farm., 1908, 47, 363—368).—Moist sulphur in a state of fine division oxidises in the air to sulphuric acid, the action being accelerated by light. In absence of oxygen, sulphur does not decompose water. Pure oxygen or hydrogen peroxide does not bring about the oxidation, and the active agent present in the air is considered to be ozone.

Metallic sulphides also oxidise in a moist state, the first products being the oxide and sulphur, the latter then oxidising to sulphuric acid. Solutions of hydrogen sulphide do not oxidise directly to sulphuric acid, the first process being the production of water and sulphur, followed by oxidation of the latter. The sulphides of iron, manganese, cobalt, gold, silver, platinum, antimony, and titanium oxidise rapidly, those of calcium, barium, strontium, potassium, arsenic, cadmium, mercury, and tin less rapidly, and those of zinc and copper very slowly.

C. H. D.

Preparation of Sulphur Trioxide. Rudolf Frank (D.R.-P. 194879).—One of the chief difficulties of the contact process for sulphuric acid is the sensitiveness of the contact material to impurities in the sulphur dioxide, and another is the maintenance of a definite temperature during the operation in order to avoid a reverse chemical change. These difficulties are overcome by compressing sulphur dioxide and oxygen under a pressure of 100 atmospheres, when a complete condensation to sulphur trioxide occurs. By rapidly releasing the pressure, the trioxide may be obtained in a solid condition without appreciable loss of vapour.

G. T. M.

Preparation of Sulphuric Acid. Oskar Bender (D.R.-P. 195810).—A mixture of oxygen and sulphur dioxide is introduced into a generator furnace in which water-gas is being produced and then burnt. The heat generated induces the combination of these gases to form sulphur trioxide, and the water produced serves to hydrate this substance, forming sulphuric acid. When air is employed, a certain amount of nitric acid is also produced, which exerts its catalytic action on the mixture of gases and increases the formation
of sulphuric acid. The furnace is fed with sulphur or sulphur-containing materials. G. T. M.

Quantitative Vaporisation of Phosphoric Acid from Phosphates in a Current of Chlorine and Carbon Tetrachloride or of Carbon Tetrachloride Only. Paul Janasch and W. Jilke (J. pr. Chem., 1908, [ii], 78, 21—28. Compare Abstr., 1907, ii, 864).—It is now found that phosphoric acid can be distilled quantitatively from calcium, sodium, or potassium phosphate if the phosphate is thoroughly ground with quartz powder and the mixture heated in a current of chlorine which has been passed through carbon tetrachloride. The calcium phosphate was heated for four hours at a dark red, and for two hours at a bright red, heat in a quartz boat, and the sodium and potassium phosphates for nine hours at a bright red heat in a gas-carbon boat, in a glass tube. The phosphoric acid distils the more quickly the slower the current of chlorine and carbon tetrachloride.

Phosphoric acid does not distil, even in traces, when magnesium phosphate is heated alone or in admixture with wood charcoal in a current of dry ammonia at a bright red heat (compare Heraeus, Abstr., 1903, ii, 82). Ammonium phosphate, on the other hand, volatilises partly in a current of ammonia, but does not attack the glass tube as when distilled in a current of carbon dioxide; the ammonium phosphate leaves a residue of vitreous phosphoric acid, which is almost insoluble in water or mineral acids.

When heated in a current of carbon tetrachloride at a moderate red heat, ferric phosphate is completely volatilised; if the cool end of the tube is packed loosely with glass-wool, ferric chloride is here deposited quantitatively, whilst the mixture of phosphorus trichloride and oxychloride, formed according to the equation

\[ \text{P}_2\text{O}_5 + 2\text{CCl}_4 = \text{PCl}_5 + \text{POCl}_3 + 2\text{CO}_2 + 2\text{Cl}, \]

is readily driven over into the receiver. G. Y.

Hydrates of the Phosphoric Acids. Henri Giran (Compt. rend., 1908, 146, 1270—1272).—The freezing-point curve of aqueous solutions of orthophosphoric acid shows two minima and a single maximum. The minima characterise two eutectics of the composition \((\text{H}_3\text{PO}_4,0'135\text{H}_2\text{O})\), m. p. 22°; and \((\text{H}_3\text{PO}_4,3'205\text{H}_2\text{O})\), m. p. —81°. The maximum at 20° indicates the existence of the hydrate

\[(\text{H}_3\text{PO}_4,1\text{H}_2\text{O}),\]

for which Joly found m. p. 27° (compare Abstr., 1885, 482). The freezing-point curve for pyrophosphoric acid is similar in form. The two eutectics correspond with the formulae \((\text{H}_4\text{P}_2\text{O}_7,1'25\text{H}_2\text{O})\), m. p. 23°, and \((\text{H}_4\text{P}_2\text{O}_7,6'87\text{H}_2\text{O})\), m. p. —75°. The maximum characterises the hydrate \((\text{H}_4\text{P}_2\text{O}_7,1'5\text{H}_2\text{O})\), m. p. 26°. This compound has been isolated as unstable needles, readily undergoing conversion into orthophosphoric acid. Measurement of its heat of dissolution proves it to be less stable than the hydrate of orthophosphoric acid.

Only a small portion of the curve for metaphosphoric acid can be studied, since solutions containing less than 63% of water are converted on cooling into a vitreous mass, which refuses to crystallise. W. O. W.
Molecular Weights of the Phosphoric Acids determined by Cryoscopy. Henri Giran (Compt. rend., 1908, 146, 1393—1396).—The molecular weights of metaphosphoric and pyrophosphoric acids in acetic acid solution diminish after a lapse of time, and finally reach a limit depending on the concentration of the solution. From extrapolation in the curve representing variation of molecular weight with age of solution, it is found that at the moment of solution, metaphosphoric acid has a molecular weight corresponding with the formula 5(HPO₃), whilst pyrophosphoric acid has the formula 3(H₃P₂O₇). The molecular weight of orthophosphoric acid varies only slightly with time; the values obtained varied from 111.9 to 127.1, according to the concentration of the solution. The acid should probably be represented by the formula (H₃PO₄)₂. Orthophosphoric and pyrophosphoric acids have the same molecular weights in the liquid as in the solid form.

W. O. W.

The Removal of Arsenic from Liquids and Gases. Chemische Fabrik Griesheim-Elektron (D.R.-P. 194864).—In order to free a liquid, such as concentrated sulphuric acid, from arsenic, it is treated with strong hydrochloric or hydrofluoric acid, and then mixed intimately with benzene. On drawing off the latter liquid, it is found to contain all the arsenic as chloride or fluoride, and, when freed from this impurity by treatment with water, it may be employed in removing arsenic from further quantities of sulphuric acid. Dichlorobenzene may also be employed for this purpose, and, owing to its higher boiling point, is preferably used in the removal of arsenic from gases by allowing it to flow down towers through which the gaseous mixtures are passing.

G. T. M.

Ammoniacal Arsenic Trichloride. Adolphe Besson and Georges Rosset (Compt. rend., 1908, 146, 1266—1267. Compare Abstr., 1890, 1052; Hugot, Abstr., 1904, ii, 559).—When dry, gaseous ammonia acts on arsenic trichloride at —20°, a bright yellow solid, AsCl₅,4NH₃, is formed; this sublimes completely when heated in a vacuum at 200°, forming a yellow, horn-like substance, 2AsCl₅,7NH₃. When the former compound is treated with liquid ammonia, it loses its colour, and remains colourless when the excess of ammonia is driven off. When extracted with liquid ammonia, ammonium chloride is removed and a white, insoluble residue obtained, the composition of which agrees with that of the imide, As₃(NH)₃. On making an intimate mixture of the portions soluble and insoluble in liquid ammonia, a substance is obtained which differs from the original compound in that it is not completely volatile at 200°, and when treated with sulphuric acid yields only a small quantity of arsenic trichloride.

These experiments lead to the conclusion that liquid ammonia acts on the compound AsCl₅,4NH₃ as a reagent, and not merely as a solvent. Arsenic trichloride also reacts with AsCl₅,4NH₃, giving rise to ammonium chloride and a substance or mixture of substances, the composition of which is indicated approximately by the formula As₅Cl₁₅N₂H₄. The identity of this product has not been established.

W. O. W.

Arsenic dissolves readily in molten tellurium. Examination of the freezing-point curve of the solution indicates the existence of the compound As$_3$Te$_3$, characterised by a maximum at 362°. This telluride crystallises in long, silver-white needles having a pale yellow tint. The freezing-point curve for solutions of bismuth in tellurium has been completely followed. A maximum occurs at 583°, corresponding with the compound Bi$_3$Te$_3$. The freezing points of solutions of these two tellurides in excess of tellurium have been determined, and the cryoscopic constant of tellurium calculated. The value $K=517$ was obtained from As$_3$Te$_3$, whilst the bismuth compound gave $K=528$. These numbers agree closely with those already determined for this constant.

By applying Robertson's formula (Trans., 1902, 81, 1233), the latent heat of fusion of tellurium is found to be 20—21 Cal.

W. O. W.

Synthesis of Boron Sulphide from Ferroboron and Manganoboron. Josef Hoffman (Zeitsch. anorg. Chem., 1908, 59, 127—135. Compare Abstr., 1907, ii, 82).—The formation of boron sulphide by passing a current of dry hydrogen sulphide over ferroboron and manganoboron at the melting point of antimony has been examined in detail. The ferroboron is more rapidly decomposed than the manganoboron, and a better yield is obtained with the former material. In both cases, only a portion of the contained boron can be converted into the sulphide.

Boron sulphide loses weight on exposure to the air, and hydrogen sulphide is evolved. It also changes when kept in the dark in closed vessels. Water, alcohol, and aqueous solutions decompose it rapidly. It is insoluble in carbon disulphide, and is decomposed slowly by ethyl ether and glycerol. Sulphuric acid reacts with the liberation of hydrogen sulphide and sulphur dioxide.

The author has attempted to ascertain whether borides of definite composition are present in the materials used in his experiments by decomposing these by treatment with aqua regia. The proportions of the constituents which pass into solution are supposed to indicate borides of the composition Fe$_3$B$_4$ and MnB.

H. M. D.

Preparation of Boron Nitride and Calcium Boride. Alfred Stock and Walter Holle (Ber., 1908, 41, 2095—2099).—Boron nitride, although easily prepared, is difficult to obtain in a pure state (Stock and Blix, Abstr., 1901, ii, 650; Moeser and Eidmann, Abstr., 1902, ii, 206). It is now found that boron nitride can be prepared by dropping boron bromide into liquid ammonia and gradually heating the resulting boronimide (Joannis, Abstr., 1904, ii, 654) to 75°. Boron nitride, so prepared, reacts only slowly with water, being dissolved in boiling water in one day. In comparison with this, however, phosphorus nitride is highly stable, only about 1% being dissolved by boiling water in two hundred hours. In a glass tube at 180°,
phosphorus nitride is completely dissolved by boiling water in a few hours, but in this case the alkali of the glass may be concerned.

The action of calcium on boron trioxide leads to the formation of almost pure calcium boride, and not to that of boron, as stated by Moissan (Abstr., 1899, ii, 153).

G. Y.

Pure Carbon Dioxide. Walter P. Bradley and C. F. Hale (J. Amer. Chem. Soc., 1908, 30, 1090—1096).—In connexion with a study of the critical state of carbon dioxide (Bradley, Browne, and Hale, Abstr., 1905, ii, 75), it was necessary to prepare the gas in the highest possible degree of purity. A method was therefore devised, and is described in the present paper, by means of which carbon dioxide can be obtained of such purity that only 1 part in 30,000—40,000 parts is incapable of absorption by potassium hydroxide solution. The gas is evolved by the action of pure sulphuric acid on sodium hydrogen carbonate, and special apparatus has been devised for its purification and collection. For details, the description and diagram in the original must be consulted.

In the course of the experiments, it was observed that rubber tubing is slightly permeable to air, even against a pressure of 50 mm. of mercury.

E. G.

L. J. S.

Preparation of Argon from Air by means of Calcium Carbide. Franz Fischer and Oskar Ringe (Ber., 1908, 41, 2017—2030).—It is shown that argon can be obtained economically from air by means of calcium carbide. The nitrogen and oxygen are both absorbed when the air is passed over a mixture of calcium carbide (90%) and calcium chloride (10%) heated at 800° in an iron vessel. The nitrogen reacts with the carbide, yielding carbon and calcium cyanamide; the oxygen forms lime and carbon; carbon monoxide and dioxide are also formed, but these ultimately react with the carbide, yielding carbon. The carbide mixture is first heated under reduced pressure in order to remove moisture from the calcium chloride, and then dry air is passed over. The issuing gas contains small amounts of hydrogen, hydrocarbons, and carbon monoxide, and is therefore passed through a vessel containing heated copper oxide. By this process, some 11 litres of argon may be obtained in the course of two days, using about 7 kilograms of carbide.

Details of the apparatus and its use are given.

J. J. S.

Percentage of the Inactive Gases in the Atmosphere. A Correction to Previous Calculations. Sir William Ramsay (Proc. Roy. Soc., 1908, 80, A, 599).—The total weights of krypton and xenon in the atmosphere calculated from the volumes (Abstr., 1903, ii, 476) are ten times too small; the true values are 0·028% for krypton and 0·005% for xenon. The values for the proportion of helium and neon previously given (Abstr., 1905, ii, 817) are 100 times too small;
the true percentage of helium is 0.000056 by weight and 0.00040 by volume; of neon, 0.00086 by weight and 0.00123 by volume. G. S.

Preparation of Alcoholic Potassium Hydroxide Solution which will Keep. FRANZ RABE (Zeitsch. Nahr. Genussm., 1908, 15, 730—743).—It is recommended that the required quantity of potassium hydroxide should be dissolved in its own weight of water, and the solution, when cold, poured into about 900 c.c. of 95% alcohol, with constant shaking. The whole is then diluted with alcohol to 1000 c.c., mixed, and placed aside until the oily drops of “aldehyde-resin” have separated. The solution is then decanted, and, at the end of about two days, is once more poured off from the separated precipitate (potassium carbonate, &c.). Filtration is unnecessary. W. P. S.

Electrolytic Production of Alkali Chlorates and Perchlorates. M. COULERU (D.R.-P. 195639).—In the ordinary electrolytic processes for chlorates, the production of free alkali hydroxide and hypochlorites diminishes the yield of the required salts. Increased efficiency, is gained by the addition of calcium salts, chromates, or dichromates. The addition of chromate may be made in alkaline, neutral, or acid solution, the best effect being obtained in the last case and the worst in the first. Practically, however, the employment of an acid solution has two disadvantages, namely, corrosion of the platinum electrodes and formation of a highly-coloured product. Accordingly, the electrolytic solution is kept neutral by the addition of salts which will interact with any alkali hydroxide to furnish either a hydroxide not affected by hypochlorite, or one which will yield a technically important product when treated with this oxidising agent. Magnesium chloride is the best example of the first type of salt, and lead chloride of the second. In the first instance, the magnesium hydroxide which is precipitated by potassium or sodium hydroxide is not materially affected by hypochlorite, and in the second, the lead hydroxide precipitated by the alkali is oxidised by hypochlorite to lead dioxide. The yield calculated on the current employed is 90% for potassium chloride and 85% for the corresponding sodium salt.

G. T. M.

Preparation of Anhydrous Sodium Thiosulphate and Hydrosulphide. VEREIN CHEMISCHER FABRIKEN IN MANNHEIM (D.R.-P. 194881 and 194882).—Dry pulverulent sodium hydrosulphide results when hydrogen sulphide is passed over sodium sulphide at 300°. If the gas contains carbon dioxide, the sodium sulphide is mixed with the calculated amount of powdered chalk.

Anhydrous sodium thiosulphate is produced by passing oxygen or air over sodium hydrosulphide at 100—150°; it is also formed when sodium sulphide is heated at higher temperatures in a current of hydrogen sulphide and oxygen.

G. T. M.

Preparation of Sodium Perborate. DEUTSCHE GOLD & SILBER SCHEIDE ANSTALT (D.R.-P. 193722).—A 50% solution of sodium peroxide prepared in the cold is saturated with carbon dioxide and
then treated with a concentrated solution of sodium metaborate. Sodium perborate separates when the liquid is cooled to 2°, providing that sufficient water is present to keep all the alkali carbonate in solution.

G. T. M.

Manufacture of Lithia from Lepidolite. WILLIAM JAY SCHIEFFELIN and THOMAS W. CAPPON (J. Soc. Chem. Ind., 1908, 27, 549—550).—A 97—99% decomposition of lepidolite can be effected by gradually heating a mixture of the ore with 10% more than its weight of sulphuric acid (66° B.) at 340°, the operation lasting about eight hours. The mass is leached with water and the silica separated; the solution is then treated with sufficient potassium sulphate to convert all the aluminium sulphate into alum. After six days, the mother liquor is decanted from the precipitated alum meal. In order to remove the alum still in solution, the liquid is first treated with whiting to neutralise the acid, and then boiled with freshly-precipitated aluminium hydroxide; practically all the alum is thereby precipitated as basic alum or alunite. A subsequent treatment with more whiting removes the last traces of alumina. The solution is then made alkaline with slaked lime and concentrated; it consists chiefly of lithium sulphate, a small amount of calcium sulphate, and traces of manganese and iron oxides. After removal of these impurities, the solution is added to potassium carbonate, and the precipitated lithium carbonate is then washed and dried.

P. H.

Electrolytic Production of Ammonium Persulphate. CONSORTIUM FÜR ELEKTROCHEMISCHE INDUSTRIE (D.R.-P. 19581).—Hitherto a good yield of ammonium persulphate has been obtained electrolytically either by the use of a diaphragm or by the addition of a chromate in ammoniacal solution. It has now been found that a saturated solution of ammonium sulphate can be electrolysed so as to give a good yield of persulphate, provided that a current density of not less than 20 amperes per sq. dcm. is employed, and that the solution is sufficiently acid not to develop an alkaline reaction in the neighbourhood of the cathode. With a current density of 300 amperes, a yield of 70% of persulphate is obtained without the use of a diaphragm.

G. T. M.

Double Chromates of Ammonium. MAX GRÖGER (Zeitsch. anorg. Chem., 1908, 58, 412—426. Compare Abstr., 1907, ii, 94, 624).—The compounds in question were prepared almost exclusively by the gradual addition of 10 c.c. of a 2N solution of the appropriate salt to 50 c.c. of an approximately 2N-solution of neutral ammonium chromate; the precipitate was allowed to remain in contact with the mother liquor for some time, then filtered rapidly, and dried on a porous plate. As many of the salts are decomposed by water, they could not be purified by washing.

Ammonium barium chromate, BaCrO₄·(NH₄)₂CrO₄, forms light yellow, cubic crystals, and the corresponding strontium salt, light yellow, spherical, crystalline aggregates; both are decomposed by water. The corresponding magnesium salt, with 2H₂O, forms yellow crystals, and is not decomposed by water.
From zinc chloride and neutral ammonium chromate solution, the compound, $4ZnCrO_4\cdot 2(NH_4)_2CrO_4\cdot 3NH_3\cdot 3H_2O$, was obtained in transparent, dark yellow, spherical granules, but with a chromate containing ammonia in excess, the compound $ZnCrO_4\cdot (NH_4)_2CrO_4\cdot 2NH_3$, already described by Briggs (Trans., 1903, 83, 391), was obtained. Two double salts containing cadmium, of the probable formulae $2CdCrO_4\cdot 2(NH_4)_2CrO_4\cdot NH_3\cdot 3H_2O$ (deep-yellow prisms) and $CdCrO_4\cdot NH_3\cdot 3H_2O$ (small, granular crystals), were also prepared. When the chromate contains excess of ammonia, the compound $CdCrO_4\cdot (NH_4)_2CrO_4\cdot 2NH_3$ separates in light yellow, prismatic crystals (Briggs, loc. cit.). Two mercury salts were also prepared, but their constitution has not been elucidated, and they were probably impure.

With cupric chloride and the chromate containing excess of ammonia, the compound $CuCrO_4\cdot (NH_4)_2CrO_4\cdot 2NH_3$ was obtained (Briggs, loc. cit.); with the neutral chromate, the same salt in an impure condition was isolated. With nickel chloride and excess of ammonium chromate, a double salt, $2NiCrO_4\cdot 2(NH_4)_2CrO_4\cdot 3NH_3\cdot H_2O$, has been obtained in small, reddish-brown prisms. Other double salts, obtained by interaction of these two reagents under different conditions, have been described previously. With cobalt chloride, the compound $3CoCrO_4\cdot (NH_4)_2CrO_4\cdot 2NH_3\cdot 3H_2O$, was obtained in dark reddish-brown granules, readily decomposed by water. With silver nitrate, the compound $3Ag_2CrO_4\cdot (NH_4)_2CrO_4$, was obtained in reddish-brown, granular crystals, and with lead acetate, the compound, $PbCrO_4\cdot (NH_4)_2CrO_4$, as an amorphous precipitate; both compounds are decomposed by water.

The Solubility of Silver Iodide in Ammonia. Henri Baubigny (Compt. rend., 1908, 146, 1263—1265; Bull. Soc. chim., 1908, [iv], 3, 772—775).—The solubility of silver iodide in aqueous ammonia increases appreciably with rise of temperature. Failure to take this into account is responsible for the discordant results of previous observers. The author shakes known weights of silver iodide (free from chloride) with a definite volume of ammonia in sealed tubes at 50—60°, and, after allowing these to cool to the desired temperature, observes whether or no crystallisation has taken place. In this way, the coefficient of solubility of silver iodide at 10° in aqueous ammonia (D 0.926) is found to be of the order 1/6000, a value considerably lower than that obtained by previous workers.

W. O. W.

Simplest Method of Preparing Carey Lea's Photo-haloids. Lüppo-Cramer (Zeitsch. Chem. Ind. Kolloide, 1908, 2, 360—361).—When the halogen salts of silver are allowed to remain in contact, or are warmed, with colloidal solutions of silver, the so-called "photo-salts" are formed. These are separated by dissolving the excess of colloidal silver in nitric acid. The coloured halogen salts are also obtained when a suitable reducing agent is added to silver nitrate which is in contact with the ordinary silver halogen salts. Suitable reducing agents are (1) sodium citrate + ferrous sulphate; (2)
sodium potassium tartrate + ferrous sulphate; (3) tannic or gallic acid + alkali carbonate; (4) formaldehyde + sodium hydroxide; (5) sodium hypophosphite.

The method of preparation described supports the author’s view that the coloured salts are adsorption compounds.

H. M. D.

[Preparation of Calcium Hypochlorites.] Chemische Fabrik Griesheim-Elektron (D.R.-P. 195896).—When a mixture of 1 part of quicklime and 6.4 parts of water is treated with chlorine until nearly all the lime is used up, a solution is obtained containing 180 to 190 grams of active chlorine and only 1 or 2 grams of chlorate per litre. This solution is then treated anew with lime and chlorine, when crystalline calcium hypochlorite is deposited. This operation may be repeated until nearly all the hypochlorite is precipitated, the action being accelerated by the addition of calcium chloride.

When milk of lime is chlorinated, a point is reached at which further introduction of chlorine does not increase the amount of active chlorine in solution, owing to the formation of basic hypochlorites of the type \( \text{Ca(OCl)}_2 \cdot x \text{Ca(OH)}_2 \). Two have been isolated in which \( x \) is 2 and 4; they cannot be obtained crystalline, owing to the circumstance that they are decomposed by water.

T. G. M.

Colloidal Barium Sulphate. Albert Recoura (Compt. rend., 1908, 146, 1274—1276. Compare Neuberg, Abstr., 1906, ii, 753).—The employment of pure glycerol as a solvent for the reacting salts when barium sulphate is prepared by double decomposition, results in the formation of a stable colloidal variety of the latter substance. The glycerol solution of the colloid can be diluted with several times its volume of water without bringing about precipitation of the insoluble form. The solution is, however, immediately coagulated on boiling. The addition of aqueous solutions of metallic salts (with the exception of mercuric chloride and salts of barium) likewise causes precipitation. Ammonia, baryta, and all monobasic acids, after several hours, bring about a gradual precipitation, whilst polybasic acids (boric acid excepted) cause immediate coagulation. Barium salts increase the stability of the colloid to a marked extent. A solution which has been rendered stable by the addition of barium nitrate can be kept for fifteen days to a month without depositing barium sulphate. Such a solution, however, is immediately coagulated by the addition of salts of polybasic acids; the salts of monobasic acids on the other hand are without action on it.

W. O. W.

Langbeinite and Vanthoffite \([\text{K}_2\text{SO}_4,2\text{MgSO}_4\text{ and }3\text{Na}_2\text{SO}_4,\text{MgSO}_4]\). Richard Nacken (Chem. Zentr., 1908, i, 1850; from Nachr. K. Ges. Wiss. Göttingen, 1907, 602—613. Compare Abstr., 1907, ii, 530).—The author has studied the temperature-concentration diagram of the systems \( \text{MgSO}_4–\text{K}_2\text{SO}_4 \) and \( \text{MgSO}_4–\text{Na}_2\text{SO}_4 \) as in previous cases.

1. Simple sulphates.—Sodium sulphate and potassium sulphate are enantiotropic dimorphous, with transformation temperatures 234° and 595°, and m. p. 883° and 1076° respectively; they do not
Double Chlorides and Bromides of Zinc and the Alkalis.

Fritz Ephraim (Zeitsch. anorg. Chem., 1908, 59, 56—70).—The products obtained by crystallisation of solutions containing chlorides and bromides of zinc and sodium, potassium, ammonium, or lithium at temperatures between about 20° and 100° have been examined.

The salt, 2KCl,ZnCl₂,H₂O, crystallises from a solution containing a slight excess of zinc chloride. On leaving the mother liquor for some days in contact with the air, the salt, KCl,ZnCl₂, separates in thick, monoclinic prisms. Solutions containing potassium chloride in considerable excess, deposit this on evaporation, and later the anhydrous double chloride, 2KCl,ZnCl₂, appears.

The salt, KBr,ZnBr₂,2H₂O, crystallises from solutions containing equal molecular proportions of the two bromides in elongated, six-sided tablets. Solutions containing 2 or more mols. of potassium bromide per mol. of zinc bromide yield very fine, hair-like needles of the composition 2KBr,ZnBr₂,2H₂O.

The already-described sodium zinc chloride, 2NaCl,ZnCl₂,3H₂O, is the only double chloride which can be separated.

The salt, NaBr,ZnBr₂,H₂O, crystallises from solutions containing zinc bromide in slight excess in hygroscopic prisms. The salt 2NaBr,ZnBr₂,5H₂O is obtained in the form of small needles from solutions containing the two bromides in the same ratio.

In addition to the double chlorides and bromides of ammonium and zinc previously described, a substance of the composition

\[ \text{NH}_4\text{Br},\text{ZnBr}_2,x\text{H}_2\text{O} \]

is obtained on evaporation of a solution containing equal molecular quantities of the simple bromides.

On evaporation of a solution containing 2 mols. zinc chloride per mol. lithium chloride, microscopic, six-sided leaflets of the basic salt, ZnO,3ZnCl₂,H₂O, separate. By slow evaporation of the mother liquor over concentrated sulphuric acid, crystals of the composition LiCl,ZnCl₂,3H₂O are obtained. From solutions containing 2 mols.

Vol. XCV. ii.
lithium chloride per mol. zinc chloride, well-formed, hygroscopic, flat prisms of the composition $2\text{LiCl}_3\text{ZnCl}_2\text{H}_2\text{O}$ crystallise.

When a solution containing 6 mols. of lithium chloride per mol. of zinc chloride is evaporated on the water-bath and cooled, lithium chloride separates; on repeating these processes until no more lithium chloride crystallises on cooling, a syrupy liquid of the composition $3\text{LiCl}_3\text{ZnCl}_2\text{H}_2\text{O}$ is obtained. This liquid, which does not lose water at 100° and does not crystallise when cooled to $-20^\circ$, is supposed to be a definite compound. The syrupy liquid, after having been kept in a desiccator for about six months, deposited crystals of lithium chloride.

H. M. D.

**Rare Earths.** Hugo Erdmann and Fritz Wirth (Annalen, 1908, 361, 190—217).—The peculiar behaviour of cerium with 1:8-hydroxynaphthalenesulphonic acid (Erdmann and Nieszytka, this vol., i, 621) led the authors to study the salts of this acid with other rare earths, as also the malonates, which, like the oxalates, serve for the recognition and separation of rare metals, since the malonates of the cerium metals are isomorphous and microcrystalline, whilst those of the yttrium earths crystallise in long spears. The sulphides of samarium and gadolinium have also been prepared.

Neodymium and samarium are separated from lanthanum and praseodymium by a long series of fractional crystallisations of didymium magnesium nitrate, $2\text{R(NO}_3)_3\text{3Mg(NO}_3)_2\text{H}_2\text{O}$, which crystallises in large plates (Demargay, Abstr., 1900, ii, 346). Lanthanum is then separated from praseodymium by Welsbach's method of fractional crystallisation of the double salts with ammonium nitrate. Samarium and gadolinium nitrates were prepared from a euxenite and from the final filtrates from the preparation of neodymium, the samarium being precipitated as the double salt with potassium sulphate, $2\text{Sa}_2(\text{SO}_4)_3\text{9K}_2\text{SO}_4\text{3H}_2\text{O}$, which crystallises from concentrated potassium sulphate solution. Europium was removed from this precipitate by Urbain and Lacombe's method (Abstr., 1904, ii, 43). The gadolinium which remains dissolved in the potassium sulphate solution was purified by fractional precipitation of the nitrate from nitric acid. The examination of the arc spectra showed that the samarium nitrate was free from neodymium, and therefore from the metals of the cerium group, but contained traces of gadolinium, europium, and yttrium; the gadolinium fraction contained only traces of samarium, dysprosium, terbium, and yttrium.

**Malonates of the Rare Earths.**—As malonic acid does not form precipitates with the salts of the rare earths, malonates were prepared by the action of malonic acid on the hydroxides; on heating the aqueous solutions, the malonates separate in crystalline form. The following malonates are described (compare Holmberg, Abstr., 1907, ii, 90); the figures in brackets are the solubilities in 100 parts of water at 18°:

- $(\text{C}_3\text{H}_2\text{O}_4)_3\text{La}_2\text{5H}_2\text{O}$ (0.0455), white crystals;
- $(\text{C}_3\text{H}_2\text{O}_4)_3\text{Ce}_2\text{5H}_2\text{O}$ (0.0141), white crystals, lose $2\text{H}_2\text{O}$ at 140°, and the remaining $3\text{H}_2\text{O}$ at 180°;
- $(\text{C}_3\text{H}_2\text{O}_4)_3\text{Pr}_2\text{6H}_2\text{O}$ (0.0179), green, crystalline powder;
- $(\text{C}_3\text{H}_2\text{O}_4)_3\text{Nd}_2\text{5H}_2\text{O}$ (0.0354);
- $(\text{C}_3\text{H}_2\text{O}_4)_3\text{Sa}_2\text{6H}_2\text{O}$ (0.0397), yellow,
granular powder; \((\text{C}_3\text{H}_2\text{O}_4\text{)}_3\text{Gd}_2\text{H}_2\text{O} (0.0616)\), strongly refracting, yellow needles; \((\text{C}_3\text{H}_2\text{O}_4\text{)}_3\text{Yt}_2\text{OH}_2\text{O} (0.1076)\), white needles; 
\((\text{C}_3\text{H}_2\text{O}_4\text{)}_3\text{Er}_2\text{H}_2\text{O} (0.1300)\), long needles. The malonates of the cerium group form prismatic, doubly refracting plates, and effloresce in air; those of the yttrium group form doubly refracting, rhombic needles. All of these salts dissolve in acids, and when boiled with alkalis form the hydroxide of the metal.

8-Hydroxynaphthalene-1-sulphonates of the Rare Earths.—The following 8-hydroxynaphthalene-1-sulphonates were prepared by the action of the acid on the carbonates of the rare metals; they separate from the boiling aqueous solution as heavy powders. The solubilities in 100 parts of water at 14° are given in brackets: 
\((\text{C}_{10}\text{H}_6\text{SO}_4\text{)}_3\text{La}_2 (0.0926—0.0987)\), white powder, dissolves in acids, forming bluish-red solutions; 
\((\text{C}_{10}\text{H}_6\text{SO}_4\text{)}_3\text{Pr}_2 (0.0709—0.0818)\), green powder, forms bluish-red solutions in acids; 
\((\text{C}_{10}\text{H}_6\text{SO}_4\text{)}_3\text{Nd}_2 (0.0171—0.0211)\), grey powder, forms yellowish-red solutions in acids; 
\((\text{C}_{10}\text{H}_6\text{SO}_4\text{)}_3\text{Sa}_2 (0.0496—0.0573)\), white powder, soluble in acids; 
\((\text{C}_{10}\text{H}_6\text{SO}_4\text{)}_3\text{Gd}_2 (0.117)\), white powder, forms bluish-red solutions in acids; 
\((\text{C}_{10}\text{H}_6\text{SO}_4\text{)}_3\text{Yt}_2 (0.0951)\), white powder, forms bluish-red solutions in acids; 
\((\text{C}_{10}\text{H}_6\text{SO}_4\text{)}_3\text{Er}_2 (0.0339)\), white powder. These salts are not hygroscopic, but absorb oxygen, becoming black on exposure to air; when boiled with alkalis, they form metallic hydroxides.

Sulphides of the Rare Earths.—These are best prepared by heating the sulphates in a current of hydrogen sulphide (Muthmann and Stüttzel, Abstr., 1900, ii, 142).

Samarium sulphide, \(\text{Sa}_2\text{S}_3\), forms a yellow mass, D 3.7, burns when heated, forming the oxide and sulphate, is decomposed only slowly by boiling water, and dissolves in acids with evolution of hydrogen sulphide.

Gadolinium sulphide, \(\text{Gd}_2\text{S}_3\), forms a hygroscopic, yellow mass, D 3.8, and behaves in the same manner as the samarium salt.

G. Y.

Scandium. Sir William Crookes (Proc. Roy. Soc., 1908, 80, A, 516—518).—As the result of spectroscopic examination of fifty-three rare-earth minerals, scandium has been detected in aurelite, cerite, keil-hauite, mosandrite, orangite, orbite, pyrochlore, thorianite, thorite, and wiikite. All these minerals contain less than 0.01% of scandium, except wiikite, which contains more than 1%.

Wiikite is a black, amorphous mineral, which, when heated to redness in a silica tube, gives off helium, water, hydrogen sulphide, a white sublimate, and traces of hydrogen, carbon dioxide, and neon. An approximate analysis of wiikite gave the following figures: tantalic acid with some niobic acid, 15.91; titanic acid and zirconia, 23.36; earths of the cerium group, 2.55; earths of the yttrium group, 7.64; scandia, 1.17; thoria, 5.51; ferrous oxide, 15.52; uranium oxide, 3.56; silica, 16.98; water and gases, 5.83; calcium, manganese, tin, sulphur, &c., 1.97.

47—2
Scandium may be separated by fractional crystallisation from the crude earths, consisting chiefly of yttria, ytterbia, and scandia; its spectrum should be free from the lines of ytterbium.

A number of salts of scandium have been prepared and analysed.

R. J. C.

New Double Salt of Thallium. Moritz Kohn (Zeitsch. anorg. Chem., 1908, 59, 111—113).—When a hot concentration solution of thallous sulphate is added to a solution containing an equal molecular quantity of uranyl sulphate acidified with sulphuric acid, intensely-coloured, yellow crystals of the double salt, Tl₂SO₄·UO₂SO₄·3H₂O, belonging to the rhombic system, separate on cooling. Solutions supersaturated with regard to the double salt are easily obtained.

H. M. D.

Freezing-point Diagrams of the Binary Systems, Cu—Cu₂Se, Ag—Ag₂Se, and Pb—PbSe. K. Friedrich and A. Leroux (Metallurgie, 1908, 5, 355—358).—The addition of selenium lowers the freezing point of copper, the eutectic point lying between 2 and 3% Se and 1063°. The curve then rises, soon becoming nearly horizontal. There is some separation into two liquid layers, the limits of which were not determined. The existence of copper selenide, Cu₂Se, melting at 1113°, is demonstrated. Copper does not form solid solutions with selenium.

Mixtures of silver with more than 7% Se separate into two liquid layers. The existence of the selenide Ag₂Se (m. p. between 834° and 850°) is indicated, but mixtures richer in selenium could not be prepared, owing to loss by volatilisation.

Only a single branch of the freezing-point curve of lead—selenium mixtures could be determined. The eutectic point lies close to the lead end. The existence of the compound PbSe, m. p. 1100°, is indicated.

C. H. D.

Non-electrolytic Solution of Mercury in Water and Other Liquids. A. Christoff (Zeitsch. physikal. Chem., 1908, 63, 346—354).—Experiments show that mercury can dissolve in, and diffuse through, water which contains air, nitrogen, carbon dioxide, sulphuric acid, or potassium hydroxide, as also through benzene, nitrobenzene, and alcohol. The mercury was covered with a layer of water (or other liquid), and the fact of its diffusion was proved by the reduction of a gold chloride solution contained in a separate vessel (compare Barfoed, Abstr., 1889, 346). In some cases, the mercury was exposed to the air, and the gold chloride solution was protected by a water seal. It is shown, also, that mercury left for a long time in contact with water suffers a slight loss in weight, although no mercury compounds can be detected in the water.

J. C. P.

Two Observations Relating to the Decomposition of Mercuric Iodide. Moritz Kohn (Zeitsch. anorg. Chem., 1908, 59, 108—110).—In alkaline solution, mercuric iodide is decomposed quantitatively by sodium arsenite, with the separation of metallic
mercury. After the solution containing an excess of arsenite has been heated to the boiling point, it is left for several hours, and the separated mercury can then be filtered off. Estimation of the iodide in the solution shows that the reaction is quantitative.

Hydrogen peroxide also liberates metallic mercury from mercuric iodide in alkaline solution. The mercury can be filtered off after one to two hours. The decomposition is not quite complete in this case.

H. M. D.

The Alumino-Silicate, \( K_2Al_2SiO_6 \). Zygmunt Weyberg (Centr. Min., 1908, 326—330).—Gorgen’s method (Abstr., 1890, 13) for preparing the crystalline compound \( K_2Al_2SiO_6 \) was tried, but better results were obtained by fusing kaolin with a large excess of potassium dichromate. The minute, colourless, isotropic octahedra which result are, however, much contaminated by enclosures of crystallised chromic oxide. Attempts to obtain other salts of the acid, \( H_2Al_2SiO_6 \), were unsuccessful.

L. J. S.

The Potassium Alumino-Silicate, \( K_2Al_2Si_2O_8 \). Zygmunt Weyberg (Centr. Min., 1908, 395—402).—By fusing kaolin or a mixture of alumina and silica with a large excess of potassium salts (chloride, carbonate, sulphate, or chromate), a minutely-crystalline product with the composition \( K_2Al_2Si_2O_8 \) is obtained. The crystals appear to be of two kinds (possibly tetragonal and orthorhombic), and to differ from the hexagonal mineral kaliophilite.

L. J. S.

Preparation of Manganese Compounds. O. Dieffenbach (D.R.-P. 195523 and 195524).—The reactivity of naturally-occurring manganese dioxide is greatly increased when it is hydrated by heating under pressure at 183° with 30% sodium hydroxide solution. The product which is obtained in a voluminous form contains the hydrate \( MnO_2 \cdot 2H_2O \).

The decomposition of an alkali manganate in aqueous solution into permanganate, manganese dioxide, and alkali hydroxide can be reversed when manganese dioxide suspended in 30% to 40% potassium hydroxide solution containing a small amount of manganate or permanganate is electrolysed in the anode compartment of an electrolytic cell. When the mixture is stirred and heated, the manganese dioxide is gradually converted into potassium manganate. Instead of manganate or permanganate, a small amount of potassium ferricyanide may be employed as the oxidising catalyst.

G. T. M.

Alloys of Iron and Carbon. Georges Charpy (Bull. Soc. chim., 1908, [iv], 3, i—xlvi).—A lecture delivered before the Chemical Society of Paris, in which a critical résumé of the results obtained in recent years in the study of iron-carbon alloys is given. The following principal lines of investigation are dealt with: (a) deduction of an equilibrium diagram by the application of the phase rule; (b) thermal investigations; (c) isolation of definite constituents from
the alloys by chemical processes; (d) microscopic examination, and (e) observation of the physical and mechanical properties of the alloys. The limits of applicability of each of these methods, and the special difficulties attending the prosecution of each, are discussed, and the bearing of the results obtained by the last four methods of research on the elaboration of a complete equilibrium diagram are considered in detail, and attention is directed to points still requiring investigation. A bibliography of the subject is appended.

T. A. H.

Steels Containing Phosphorus. J. de Kryloff (Rev. de Métallurgie, 1908, 5, 355—360).—The brittleness of steels containing small quantities of phosphorus may be removed by quenching in oil and re-heating to 750°. In this way, a uniform structure is obtained if the phosphorus does not exceed 0.07%. A larger proportion of phosphorus prevents the uniform distribution of ferrite and pearlite.

C. H. D.

The Rusting of Iron. J. Newton Friend (J. Iron Steel Inst., 1908, 77, i, 5—32. Compare Moody, Trans., 1906, 89, 729; Proc., 1907, 23, 84; Tilden, Trans., 1908, 93, 1356).—Boiling pure iron or steel with distilled water in a Jena glass reflux apparatus for two hours does not dissolve any iron. The contrary result of Walker, Cederholm, and Bent (Abstr., 1907, ii, 875) is to be attributed to the retention of some carbon dioxide by the water. An apparatus was devised in which water could be distilled from sodium hydroxide solution on to iron in a closed bulb, and in this case rusting did not take place. In another apparatus, iron was immersed in pure water, and a current of air free from carbon dioxide bubbled through the apparatus. Rusting did not take place if the iron was protected from contact with the glass, although the admission of ordinary air at once caused rusting. It is considered, in agreement with Moody, that the presence of an electrolyte is necessary to the formation of rust. Cast iron rusts even in pure air and water, probably owing to the oxidation of the sulphide and phosphide present. Pure steam is also without action on pure iron at 100°.

Neutral or alkaline hydrogen peroxide is without action on pure iron, although cast iron is rapidly attacked. Pure iron powder, freed from adhering films of gas, is not acted on by pure water at the ordinary temperature.

Neutral salts of the alkali metals exert a corrosive action, and, if the iron is in immediate contact with glass, local corrosion takes place at the point of contact.

C. H. D.

Conductivity of Solutions of Ferric and Ferrous Chlorides and the Structure of Ferric Chloride. Wladimir Jufereff (Zeitsch. anorg. Chem., 1908, 59, 82—86).—Measurements have been made of the electrical conductivity of concentrated solutions of the two chlorides of iron. The greater conductivity of the ferric solutions at dilutions greater than about 3·6 litres per mol. is interpreted in terms of an opinion expressed by Spring that ferric chloride in solution has the constitution Fe₂Cl₄·Cl₂. Chlorine is supposed to be
Magnetic Oxides of Chromium. Ivan Shukoff (Compt. rend., 1908, 146, 1396—1397).—Chromium trioxide decomposes at 330° with loss of oxygen and development of heat. If the decomposition is controlled so that the temperature does not rise above 500°, the oxides obtained are only feebly magnetic. On heating, however, to 500—510°, 13—14% of oxygen is evolved, and the black mass, which has the composition 2CrO₃·Cr₂O₃, is strongly magnetic. An oxide of the same composition, but prepared at 485°, was very feebly magnetic. A crystalline magnetic oxide was obtained by the decomposition of chromyl dichloride; when ignited, it loses only 3·4—4% of oxygen.

W. O. W.

Molybdo-Uranic Compounds. André Lancien (Chem. Zentr., 1908, i, 1763—1764; from Bull. Sci. Pharm., 1908, 15, 132—140. Compare Abstr., 1907, ii, 697).—When uranium nitrate is added to an excess of ammonium heptamolybdate and the resulting precipitate boiled with molybdic acid, uranium heptamolybdate, 7MoO₃·3UO₃, is obtained as an amorphous, yellow powder. It is soluble in all mineral acids, giving a greenish-yellow, fluorescent liquid; it is decomposed by excess of water, and reduced to green uranium molybdate, U(MoO₄)₂, by alcohol and by acetic acid. The effect of sunlight on the heptamolybdate is to darken its colour, and to render it no longer reducible by alcohol or completely soluble in nitric acid, owing to the formation of insoluble anhydrous uranium octamolybdate, 8MoO₃·UO₃. The hydrated compound, 8MoO₃·UO₃·13H₂O, is obtained as prismatic needles when ammonium heptamolybdate is precipitated by uranium nitrate and the product treated with excess of acetic acid; the substance obtained is extremely sensitive to light. A study has been made of the rate of change of this substance when exposed to light of various wave-lengths.

J. V. E.

A New Iodide of Titanium, Titanous Iodide, TiI₂. Edouard Defaccoz and H. Copaux (Compt. rend., 1908, 147, 65—67).—Titanium tetraiodide (Hautefeuille, Bull. Soc. chim., 1867, [ii], 7, 201) is reducible by silver or mercury to a di-iodide. The reduction is most readily effected as follows: Two porcelain boats, the anterior one containing mercury and the posterior one titanium tetraiodide, are introduced into a porcelain tube and heated gradually in a current of hydrogen to dull redness. A sublimate of mercuric iodide and unchanged tetraiodide is formed in the cooled receiver, whilst fine brilliant black lamellae of titanous iodide, TiI₂, are formed near the exit end of the tube. The crystals, which are very hygroscopic, have D²₀ 4·3, are not acted on by organic solvents, are dissolved by concentrated hydrofluoric acid and by boiling hydrochloric acid, forming a blue solution, are violently attacked by nitric and sulphuric acids with loss of iodine, and are decomposed by water and aqueous alkali solutions. Titanous iodide forms additive compounds with dry ammonia and hydrogen chloride. It is reduced by hydrogen at a white heat, but
not at a red heat, giving amorphous titanium, which is very readily oxidised.

The analysis was carried out by the method described previously (Abstr., 1898, ii, 521).

Titanium Nitride and a New Class of Titanium Compounds, the Titaniumnitrogenhaloids. Otto Ruff and Fritz Eisner (Ber., 1908, 41, 2250—2264).—Wöhler showed originally that a nitride was formed on heating the compound of titanium tetrachloride and ammonia (Annalen, 1850, 73, 43), and described four nitrides. Friedel and Guérin (this Journ., 1877, i, 168) reduced this number to two, Ti₅N₂ and Ti₇N₄. The latter substance has been found by Schneider (Abstr., 1895, ii, 169) to contain less nitrogen than that required by the formula, and he called it nitride A. A re-examination of the substance shows that Ti₃N₄ does not exist. The bluish-black product, obtained by heating the compound TiCl₄·6NH₃ at the temperature at which Jena glass softens in a stream of ammonia, contains Ti = 72.1, N = 20.77, Cl = 2.64, O = 4.36 (Ti₃N₄ requires Ti = 72.0, N = 28.0). The total titanium was determined by dissolving the nitride in nitric and hydrofluoric acids, and precipitating the titanic acid by ammonia. When the substance is covered with dilute sulphuric and hydrofluoric acids and titrated with N/10 potassium permanganate, the nitride goes slowly into solution as the permanganate is reduced. The solution contains hydrochloric and some pertitanic acids; the latter is destroyed by potassium iodide, and the iodine separated estimated by thiosulphate. In this way, Ti, 52.7%, was found. As a blank determination with pure TiN gave 76.9 instead of 77.1, the conclusion is drawn that the 52.7 represents the titanium present in the tervalent condition, and, as the chlorine is supposed to exist as TiNCl, the composition of the Wöhler-Schneider nitride is deduced to be TiN = 68, TiNCl = 7·2, (TiN)₂O ≈ 13·3, and TiO₂ ≈ 5·4. When this mixture is heated in a current of ammonia at 1500° for six hours, the chlorine and oxygen are removed completely, and pure bronce-coloured titanium nitride, TiN, is obtained, D₁⁸ 5·1. It could not be converted into the chloronitride by chloride either at 270° or in the liquid state.

An attempt to prepare the nitride, Ti₅N₄, from the so-called titanamide (Stähler, Abstr., 1906, ii, 595) also resulted in failure. It is also shown that continued extraction of the compound TiCl₄·6NH₃ with ammonia in a Stock and Blix apparatus (Abstr., 1901, ii, 650), moisture being excluded, does not give titanamide at all, but a titanochloroamide of the composition Ti₁·₀Cl₁·₄₈N₀·₈₆₃·₅—5NH₃·₀·₀₂TiO₂. The ammonia is removed by careful heating in a vacuum at 270°, and a dirty green residue of titanium chloronitride, TiNCl, is obtained, containing; however, 1·3% nitride and 12—14% titanium oxynitride and titanium dioxide. It is extraordinarily reactive towards water, taking fire and giving ammonium chloride, nitrogen, and titanium dioxide. On further heating, it decomposes, thus: 4TiNCl = 3TiN + TiCl₄ + N₂.

Although pure titanium chloronitride was not obtained, the corresponding bromonitride, TiNBr, is formed from titanium tetrabromide.
(m. p. 39°, b. p. 230°) in a similar manner, the heating of the product obtained on extraction with ammonia being carried out at 200°/4 mm. It also reacts vigorously with water.

Preparation and Properties of Zirconium Tetrafluoride. Ludwig Wolter (Chem. Zeit., 1908, 32, 606—607).—The method described by Marignac (Jahresb., 1860, 136) for the preparation of zirconium tetrafluoride by heating zirconium dioxide mixed with twice its weight of ammonium hydrogen fluoride, has the disadvantage that this substance volatilises more readily than it attacks the zirconium dioxide. This, however, can be overcome by using, instead of the above mixture, pure zirconium ammonium fluoride, ZrF₄·2NH₄F, which is readily prepared in a pure state by evaporating zirconium dioxide with excess of silica-free hydrogen fluoride and ammonia, and subliming the product in a platinum tube in a current of nitrogen.

Theoretical yields of the purest zirconium tetrafluoride are obtained by the action of anhydrous hydrogen fluoride on pure zirconium tetrachloride, the change readily taking place in accordance with the equation ZrCl₄ + 4HF = ZrF₄ + 4HCl. The product obtained is snow-white, crystalline, and practically insoluble in water. When sublimed, zirconium tetrafluoride forms small, strongly refracting, prismatic crystals having slightly curved facets, D₁₆ = 4·4333, and the molecular weight determined by Victor Meyer's method was found to be 166·1, in close agreement with ZrF₄ (166·7). Unlike the other elements of the carbon group, zirconium tetrafluoride is only sparingly soluble in water, 1·388 grams dissolve in 100 c.c. of water without hydrolysis taking place. When warmed to about 50°, the hydrate, ZrF₄·3H₂O, is precipitated; in no case could any other hydrate or oxyfluoride be obtained. With liquid ammonia, zirconium tetrafluoride gives a white powder (5ZrF₄·2NH₃), whilst with gaseous ammonia, pyridine, hydrogen sulphide, &c., practically no change takes place. It is suggested that this inactivity of the zirconium tetrafluoride compared with other members of the group is perhaps due to its small molecular volume: TiF₄, 44·3; ZrF₄, 37·5; SnF₄, 40·7.

Oxides of Quinquevalent Bismuth. Alexander Guthier and H. Micheler (Zeitsch. anorg. Chem., 1908, 59, 143—145. Compare Guthier and Bünz, Abstr., 1906, ii, 174, 234, 551, 678; Ruff, this vol., ii, 298).—The bismuthic acid described by Ruff is entirely different from the substance which is usually referred to by this name in the older literature. In order to avoid confusion, Guthier and Bünz considered it necessary to retain the name bismuthic acid for a particular product obtained under specified conditions. This substance, which is formed from the dark brown oxidation products (obtained by oxidation of bismuth trioxide in presence of potassium hydroxide solution) by the action of hot concentrated nitric acid, has a colour which varies from scarlet-red to yellowish-red. It has no acid properties, and cannot be obtained from any of the sodium bismuthates which have been described.
In general, the substances obtained by Ruff cannot be compared with those obtained by Gutbier and Bünz. This view is expressed as a result of a repetition of Ruff's experiments by the authors.

H. M. D.

Use of Iridium Crucibles in Chemical Operations. Sir William Crookes (Proc. Roy. Soc., 1908, 80, A, 535—536).—An account is given of the behaviour of pure wrought iridium crucibles during several months' use in ordinary quantitative estimations. Iridium is as hard as steel, and does not blister or alter in weight when repeatedly heated to redness. Heated for some hours in a Bunsen flame with insufficient air supply, the crucible is unharmed, as the deposit of carbon can be entirely burnt away. Sulphur in the gas is also without effect. Boiling aqua regia, fused microcosmic salt, or other phosphates with frequent additions of carbon, strongly heated silica or silicates with a reducing agent, boiling lead at white heat, boiling zinc, and molten nickel, iron, or gold are without effect on the crucible, which, after cleaning, retains its original weight. Fused potassium hydroxide attacks iridium less than platinum, and zinc run in with acid zinc chloride and then heated to boiling only superficially attacks the iridium. Prolonged heating with copper renders the crucible brittle when hot, but the copper can be burnt off. A rhodium crucible is practically as resistant as an iridium one, and has the advantage of being cheaper and only half as heavy.

R. J. C.

Alkali Iridichlorides and Iriodochlorides. Marcel Delépine. (Compt. rend., 1908, 146, 1267—1269).—The iridichlorides of potassium, rubidium, caesium, and ammonium, obtained from sodium iridichloride by double decomposition, conform to the type IrCl$_6$M$_2$. The potassium and sodium salts are black. Large crystals of the ammonium salt are black, but small crystals have a red tint. The rubidium salt varies from brownish-red to brick-red, according to the size of the crystals. The caesium salt, IrCl$_6$Cs$_2$, is bright red and sparingly soluble in water.

The iridochlorides are readily prepared from the iridichlorides by reduction with a normal oxalate. Thus sodium iridochloride and sodium oxalate yield the very soluble sodium salt, IrCl$_6$Na$_3$12H$_2$O. Aqueous solutions of the potassium and ammonium salts are decomposed by water, thus, IrCl$_6$M$_3$ + H$_2$O $\rightleftharpoons$ IrCl$_5$(H$_2$O)M$_2$ + MCl; hence to obtain the trimetallic salts excess of an alkali chloride must be added. The crystals which separate are black, brownish-red, green, or yellow, according to size; on dehydration they become olive-green. The dimetallic iridochlorides separate from the mother liquor on concentration. The potassium salt, IrCl$_5$(H$_2$O)K$_2$, crystallises in needles; the ammonium salt in octahedra.

Dirubidium aquoiridipentachloride, IrCl$_5$(H$_2$O)Rb$_2$, forms small, thick crystals. The caesium salt, IrCl$_5$(H$_2$O)Cs, crystallises in small, olive needles. Trirubidium iridochloride crystallises in needles containing 1H$_2$O, and not 1$\frac{1}{2}$H$_2$O as usually represented. The caesium salt, IrCl$_6$Cs$_3$H$_2$O, forms bright olive needles.

In accordance with the requirements of Werner's theory for the
constitution of these salts, it is found that the trimetallic salts readily lose their water of crystallisation; the dimetallic salts of the type \( \text{IrCl}_5(H_2O)_2M_2 \), on the other hand, undergo no change when heated at 150°.

W. O. W.

The Preparation of Alkali Iridiochlorides. **Maurice Vézes** *(Compt. rend., 1908, 146, 1392—1393).*—A claim for priority (compare Abstr., 1899, i, 572, and Delépine, preceding abstract).

W. O. W.

**Mineralogical Chemistry.**

---

An Old Occurrence of Argyrodite at Freiberg. **Friedrich Kolbeck** *(Centr. Min., 1908, 331—333).*—A specimen in the A. G. Werner collection at Freiberg was labelled "dunkles Rotgulden," and had been found in 1817 in the Bescheert Glück mine. It is a portion of a large, indistinct crystal with an iron-black colour. On examination, it proved to be the rare mineral argyrodite, in which germanium was discovered. Analysis by T. Döring gave the following results, agreeing with Penfield's formula \( \text{Ag}_8\text{GeS}_6 \):

Vanadium [Sulphide] from Minasragra. **José J. Bravo** *(Chem. Zentr., 1908, i, 1793; from Oesterr. Zeitsch. Berg-Hüttenwesen, 1908, 56, 166—168).*—In an inclined strata of impure carbon of an asphalitic nature, there occur compact masses, 1—2 metres in diameter, composed of a mixture of sulphur, clay, coal-like substances, and vanadium sulphide. The colour of the fresh fracture is pale lead-grey, but the colour rapidly darkens when exposed to the air. An analysis gave:

This previously unknown naturally-occurring vanadium sulphide is called *Rizopatronite*; it has D 2·456, hardness 3·5, amorphous with a transitory metallic lustre, and is soluble in cold alkali and aqueous ammonia.

J. V. E.

The So-called Leesbergite. **Willy Bruhns** *(Mitt. Geol. Landesanst. Elsass-Lothringen, 1908, 6, 303—307).*—This name has been given by Blum *(Ann. Soc. géol. Belgique, 1907, 34, Bull., 118—120)* to a white, chalky mineral from the Victor iron-mine, between Marspich and Hayingen, in Lorraine; from the analysis (1) he gave, the formula was deduced as \( 2\text{MgCO}_3\text{CaCO}_3 \). The material
has much the appearance of hydromagnesite; in some parts it is harder and more compact, and in others, softer and looser in texture. In contact with water, the material soon falls to powder, but it does not absorb water as stated by Blum. Under the microscope, it is seen to consist of an aggregate of minute, strongly birefringent grains. Analyses II—IV are of different samples of material dried at 100°:

The material is thus not constant in composition, and is without doubt a mixture of a mineral allied to hydromagnesite,

\[3\text{MgCO}_3\cdot\text{Mg(OH)}_2\cdot3\text{H}_2\text{O}\],

with calcite or dolomite.

L. J. S.

A Chemical Difference between Orthoclase and Microcline. **PHILIPPE BARBIER** (*Compt. rend.*, 1908, 146, 1330—1332).—Twenty-five orthoclases and five microclines were decomposed by hydrofluoric and sulphuric acids, and the alkali chlorides examined spectroscopically. All the orthoclases contained small amounts of either lithium or rubidium, and sometimes both of these elements were present together, whilst in microcline they were absent. It is therefore considered that orthoclase and microcline are distinct species, and that they may be distinguished by this method.

L. J. S.

[Celadonite from the Færöes.] **JAMES CURRIE** (*Trans. Edinburgh Geol. Soc.*, 1907, 9, 1—68).—A detailed account is given of the topographical mineralogy of the Færöes. The following analysis, by T. F. Cowie, is given of celadonite from Stigafjall in the island of Strömø. The material lines amygdaloidal cavities in the basaltic rocks, being thicker at the bottom and colouring the associated heulandite up to a certain level in the cavities.

* Including FeO. † Including Na₂O.

At 100° the loss of water is 3·34%, and the remainder is expelled at 180°. This analysis differs considerably, especially in the large content of alumina, from those of material from other localities, suggesting that celadonite or “green earth” is not a definite mineral species.

L. J. S.

Japanese Zeolites. **KOTORA JIMBŌ** (*Beiträge zur Mineralogie von Japan*, 1907, No. 3, 115—120).—A description is given of analcite, apophyllite, heulandite, chabazite, and stilbite from Japanese localities Analysis I, by Tsukamoto, is of optically anomalous crystals of analcite from Maze. [The original paper makes no comment on the fact that this composition is most unusual for analcite; probably there is some error.] II is of large, pale green, optically anomalous
crystals of apophyllite from Maze, where the mineral occurs with analcite, natrolite, and calcite in a basalt-agglomerate. III is of crystals of heulandite from Hatsuneura, in the island of Chichijima; and IV is of sheafs of stilbite from Obara.

T. A. H.

A New Mineral Occurring with Tourmaline in Madagascar. **ALFRED LACROI (Compt. rend., 1908, 146, 1367—1371).**—The pegmatite-veins intersecting crystalline limestones and mica-schists in the neighbourhood of Mt. Bity contain in their cavities crystals of smoky quartz, microcline, lepidolite, lithia tourmaline (often of gem quality and in very large crystals, which are often prominently zoned with different colours), beryl, and, in one instance, spodumene (colourless and the violet variety, kunzite). At Maharitra, the pegmatites contain a new mineral, which is described under the name *bitjyite*. It occurs as small, yellowish-white, hexagonal prisms, which are horizontally striated, and often aggregated in barrel-like shapes, in rosettes, or as a continuous crust over the other minerals. There is a perfect cleavage parallel to the basal plane. D 3·05, H 5½. Optically, the crystals are pseudo-hexagonal, showing a division into six sectors, each with a small angled negative bisectrix perpendicular to the basal plane. The refractive index is 1·62—1·64. Before the blowpipe, the mineral is readily fusible to an opaque, white, blebbly glass; it is not attacked by acids. Analysis by F. Pisani gave:

<table>

This gives the formula

10SiO₂₉,8Al₂O₃₅,5₂(Ca,Gl,Mg)₀,₁₂(Li,Na,K)₂O,0,7H₂O.

The water is expelled only at a very high temperature, and the formula may therefore be written as 5SiO₂₉,4Al₂O₃₇(R₂O + RO). The mineral may be classed as a basic orthosilicate in the staurolite and kornerupine group.

L. J. S.

Ilvaite from Shasta Co., California. **BASIL PRESCOTT (Amer. J. Sci., 1908, [iv], 26, 14—16).**—Massive and crystallised ilvaite occurs at Potter Creek, in Shasta Co., in connexion with ore-bodies of
magnetite at a contact of limestone with diorite. The mineral is of contact-metamorphic origin, and is associated with hedenbergite. The crystals are bright, with a sub-metallic lustre and a greenish-brown streak. The following analysis by H. R. Moss agrees with the usual formula:

L. J. S.

Amount of Dissolved Organic Carbon Compounds in the Sea, and their Significance in its Internal Economy. Martin Henze (Pflüger's Archiv, 1908, 123, 487—490; Zeitsch. alg. Physiol., 7, 283, 321; Abh. K. Ges. Wiss. Göttingen. Math.-physiol. Klasse, [2], 6, 1).—Pütter has claimed that by the oxidation of the organic matter contained in sea-water, using Messinger's dichromate method, from 18 to 30 mg. of carbon dioxide per 100 c.c. can be obtained, and he stated that the organic matter to which this corresponds serves as nutrition for some of the lower organisms. The author has re-estimated the carbonic acid obtainable by the oxidation of organic matter in sea-water, using antimony for the absorption of the chlorine and other modifications of the Messinger method required in the case of sea-water. He only succeeded in obtaining from 0.4 to 3.5 mg. of carbon dioxide from 100 c.c., quantities which are within the limits of experimental error. He concludes, therefore, that Pütter's hypothesis entirely lacks experimental confirmation.

S. B. S.

Physiological Chemistry.

Influence of Oxygen on Respiration. Marcus S. Pembrey and F. Cook (Proc. physiol. Soc., 1908, xli—xlii; J. Physiol., 37).—If a person breathes air or oxygen in and out of a spirometer, the breaking point is chiefly determined by the amount of carbon dioxide present. But after exercise, it is easier to breathe oxygen than air in this way, and the breaking point occurs when the amount of carbon dioxide reaches a higher level. This is regarded as supporting the old view that the hyperpnoea of muscular exercise is due in part to products of metabolism other than carbon dioxide.

W. D. H.

Effects of Excess of Carbon Dioxide and Want of Oxygen on the Respiration and Circulation. Leonard Hill and Martin Flack (J. Physiol., 1908, 37, 77—111).—Carbon dioxide at pressures from 15 to 30% causes hyperpnoea and convulsive breathing; above 30 to 35%, the excitatory effect is transient, and the narcotic effect produced may lead to respiratory arrest. Moderate doses raise the blood pressure and excite the vagus and vaso-motor centres. With higher concentrations, the blood pressure falls, owing to the depressant
effect on the heart. Pure air and massage lead to recovery of the heart. On account of the excitatory effect of the gas, a mixture containing 5% of it should be employed in resuscitating cases of carbon monoxide and nitrite poisoning. The effect of want of oxygen is a dyspnoea much more gradual in onset, and terminating in a convulsive stage of great intensity. The blood pressure is usually, but not always, raised, and the vagus centre is excited, especially in the convulsive stage. The pressure then falls. The heart is not so rapidly depressed as in carbon dioxide poisoning.

The inability to hold the breath depends more on want of oxygen than on excess of carbon dioxide. The power to hold the breath is increased by breathing excess of oxygen. Breathing in and out of a small closed space extends the power to resist alterations in the gases, because the circulation is not mechanically impeded as it is when the breath is held. In muscular exercise, excess of carbon dioxide rather than want of oxygen excites hyperpnoea. Haldane and Priestley are right in stating that normal breathing is regulated by carbon dioxide tension in the alveoli, but in cases of obstructed aeration of the blood, diminished oxygen tension is the more potent agent. W. D. H.

The Residual Nitrogen of the Blood. Hermann Hoilweg and Hans Meyer (Beitr. chem. Physiol. Path., 1908, 11, 381—403).—The serum was coagulated in the presence of a mixture of equal parts of 1% acetic acid and 5% potassium phosphate solutions, so much of this mixture being added that the resulting liquid was distinctly acid to litmus, but neutral to Congo-red. Before coagulating this acidified mixture, it was diluted, and the diluted liquid half-saturated with sodium chloride. The blood was obtained from the femoral arteries of dogs. In one series of experiments, three samples of blood were withdrawn from each animal at three different periods, the first and last being withdrawn about seven hours after a meal, and the second during a period of starvation. In the second series of experiments, three samples were also withdrawn from each animal, the first and third during a period of starvation, and the second during the height of digestion. The total residual nitrogen was estimated in each sample, as well as that fraction which was precipitable with tannic acid; the urea was also estimated, the methods of Pflüger, Schön dorff, and Möörner-Sjöqvist being employed. It was found, as a mean of all the experiments, that the total residual nitrogen of serum obtained during periods of starvation was 0.0525 gram per 100 c.c., whereas in the serum obtained during digestion it was 0.0788 gram; of these quantities, 0.0384 and 0.0567 gram were due to urea. The fraction precipitable with tannic acid showed no definite relationship to the state of nutrition. There was a small increase of the fraction not precipitable with tannic acid (exclusive of urea) in samples from the well-fed as compared with those from starving animals (0.0130 gram and 0.0060 gram respectively). The increase is too small for any definite conclusions to be drawn as to the circulation of the end products of digestion on the serum. Neither could any very definite increase of such products be detected in the serum after the addition of amino-acids and albumoses to the ordinary diet.

S. B. S.
The Action of Lipoid-soluble Substances on Red Blood-corpuscles. Isidor Traube (Biochem. Zeitsch., 1908, 10, 371—379). —If the theory already advanced as to osmosis (this vol., ii, 565) is correct, solutions with the same surface tension, excepting acids and bases which exert a chemical action, should have the same haemolytic capacity. Experiments were made to test this theory, and the results seem to confirm it.

Substances which at a certain concentration were found to act haemolytically, acted anti-haemolytically below that concentration.

S. B. S.

The Complex Hæmolyins. H. Tsurasaki (Biochem. Zeitsch., 1908, 10, 345—353).—Urea, the most important final product of metabolism, inhibits lipolysis, acting on the complement, but not on the amboceptor. Thiocarbamide and urethane also exert inhibitory action.

The conception of Sachs and Tsuruuchi that certain sera lose their haemolytic capacity, owing to the presence of a ferment which destroys the complement at 37° and acts only in the diluted serum, was confirmed by some experiments on dogs' serum. After diluting the serum to 1 in 5, the complement was entirely destroyed by incubating for two hours at 37°.

S. B. S.

Lipolysis, Agglutination, and Hæmolysis. IV. Carl Neuberg (Biochem. Zeitsch., 1908, 11, 400—403).—An attempt was made to separate a substance producing lipolysis from one producing hemolysis or agglutination, but without success. The experiments were carried out with ricin and with pancreatic juice. Red blood-corpuscles adsorb the agglutinin; after such treatment, however, the lipolytic function was also lost. Fibrin also adsorbs agglutinin, but a ricin solution treated with fibrin lost its lipolytic properties at the same rate at which it lost its agglutinating properties. Other adsorbents of agglutinins and haemolysins, such as kaolin, lead to similar results. It seems probable from the experiments that the lipases play an important part in the phenomena of immunity.

S. B. S.

Hæmolysis. Svante Arrhenius (Biochem. Zeitsch., 1908, 11, 161—171).—Hæmolysis by means of acids was investigated, and it was found that within certain limits there is a minimum action; both by increasing or diminishing the amount of acid above or below
this limit, the haemolysis is increased. This is due to protein coagulation, which within these limits inhibits the setting free of the haemoglobin from the corpuscles.

From experiments carried out with suspensions of corpuscles of varying concentration (suspensions of 0.1% to 5%), it was found that the quantity of substance necessary to produce haemolysis was a linear function of the corpuscle concentration. The corpuscles take up the haemolysing substance, and haemolysis follows when a certain relationship exists between the concentration of this substance in the envelopes and that in the surrounding fluid. An equation can be found by means of which the relative quantities of various haemolysins taken up by the envelopes can be ascertained from experimental data.

Lecithin was found to increase the haemolytic action of acids, especially if allowed to remain in contact with the corpuscles before the acid was added. It has no action on the haemolytic power of alkalis, and inhibits that of saponin. Alcohols and ether increase the haemolytic action of cobra poison, and diminish that of saponin. Sodium oleate increases also the action of cobra poison, diminishing that of saponin. Calcium chloride diminishes the action of the sodium oleate on the cobra poison, this being due, as the author points out, to the formation of an insoluble salt. It is assumed that the lecithin action of acids is due, on the other hand, to increased solubility.

S. B. S.

The Mechanism of Haemolysis by Saponin. Kurt Meyer (Beitr. chem. Physiol. Path., 1908, 11, 357—364).—The haemolytic action of saponin (Merck) on different species of blood-corpuscles was investigated. It was found that those corpuscles containing the largest amount of cholesterol were most resistant to the haemolytic action.

S. B. S.

Effect of Diet on the Amylolytic Power of Saliva. C. Hugh Neilson and D. H. Lewis (J. Biol. Chem., 1908, 4, 501—506).—Previous results on the influence of diet on animals' saliva are contradictory. The present experiments were performed on human saliva. The amylolytic power rises with carbohydrate, and falls with protein, diet.

W. D. II.

Assimilation of Protein Introduced Parenterally. Wilhelm Cramer. Assimilation of Protein Introduced Enterally. Harold Pringle and Wilhelm Cramer (J. Physiol., 1908, 37, 146—157, 158—164).—Evidence is adduced that egg-white introduced parenterally is partly assimilated and partly eliminated in the urine. The portion which is assimilated is believed to be taken up by the leucocytes. During ordinary absorption from the intestine, the leucocytes are also considered to play an important part. The intestinal mucous membrane is richer in non-coagulable nitrogen than during a fast, and this increase is most marked in the lymphoid nodules of the intestine. The blood of digesting animals shows a
small, but distinct, increase in residual nitrogen over that of fasting animals, and part of this is ascribed to the corpuscular elements.

W. D. H.

Influence on Internal Hæmorrhage on Protein Metabolism. Fred S. Weingarten and Burrill B. Crohn (Amer. J. Physiol., 1908, 22, 207—244).—Internal haemorrhage was imitated in dogs by transferring blood to the extent of 2·8 to 3·5 of the body weight from the femoral artery into the abdominal cavity. There was a slight rise of the specific gravity of the urine on the days when this was done, and a very slight rise in the excretion of nitrogen, sulphur, and phosphorus. Many other points in metabolism, secretion, composition of urine, &c., were investigated, but with wholly negative results.

W. D. H.

The Occurrence of Urocanic Acid in a Pancreatic Digest. Andrew Hunter (Proc. physiol. Soc., 1908, xxxvii—xxxviii ; J. Physiol., 37).—From a long-continued pancreatic digest of plasmon, a substance having the elementary composition and other properties of Jaffe's urocanic acid (C$_{12}$H$_{12}$O$_4$N$_4$) was isolated.

W. D. H.

Relative Rate of Absorption of Optically Isomeric Substances from the Intestine. Henry D. Dakin (J. Biol. Chem., 1908, 4, 437—438).—It is well known that isomerides differing in optical action are assimilated to varying degrees by the animal organism. The present experiments performed on intestinal loops with the optically differing lactic acids and other substances gave no evidence of any selection during the preliminary process of absorption.

W. D. H.

G. B.

The Difference between Isomotic and Isotonic Solutions in Artificial Parthenogenesis. Jacques Loeb (Biochem. Zeitsch., 1908, 11, 144—160).—The first question considered is how a hypertonic solution brings about parthenogenesis. The solution is not so much an exciting as a correcting agent. The excitant is the formation of an artificial membrane of lipoid nature (principally lecithin) at the periphery of the egg. The second question dealt with is that isomotic solutions for the egg are in general not isotonic.

W. D. H.

The Glycogenic Changes in the Placenta and the Fœtus of the Pregnant Rabbit; a Contribution to the Chemistry of Growth. J. Lochhead and Wilhelm Cramer (Proc. Roy. Soc., 1908, 80, B, 263—284).—Analyses were made of the glycogen in the maternal and foetal placenta of rabbits, as well as in the foetal liver and the remaining part of the foetal bodies, which were removed from pregnant animals in different stages of gestation from the fourteenth day
onwards. The placenta was mechanically separated into maternal and foetal parts, and the glycogen in each of these parts was estimated separately. The greater part of the placental glycogen was found in the maternal placenta. It was found that the percentage of this glycogen diminished from the eighteenth day onwards, whereas that in the foetal liver increased. It was also found that there is a distinct parallelism between the growth of the foetus and the amount of glycogen which it contains. The conclusion was drawn that the placenta of the rabbit has the function of depositing glycogen as a store of carbohydrate for the needs of the foetus. The investigation of the distribution of the glycogen-splitting enzyme led to the conclusion that the glycogen is absorbed from the maternal placenta in the form of a simpler carbohydrate, the transformation of the glycogen taking place in the placenta by the action of a secreted enzyme. In the earlier stages of intra-uterine life, the liver of the foetus does not appear to possess the power of storing glycogen; the power is not acquired until the last week of gestation. In the earlier stages of uterine life, therefore, the placenta fulfils the hepatic functions so far as glycogen is concerned. Investigations were also undertaken on the effect of variations of diet and of phloridzin injection, and it was considered from the results obtained that the glycogenic metabolism of the placenta and foetus is independent of that by the mother, and is governed by conditions in many respects different from those which regulate the metabolism of the adult animal. The glycogenic metabolism of the rabbit is different from that of the sheep and cow.

S. B. S.

**Temperature-coefficient of Rate of Conduction in Nerve.**

**Keith Lucas.** Temperature-coefficient of Rate of Conduction and Latent Period in Muscle. W. J. Woolley (J. Physiol., 1908, 37, 112—121, 122—129).—Maxwell found the temperature-coefficient for conduction in molluscan nerve to be 1·78. The present figures for amphibian nerve give a mean of 1·79. Conduction in amphibian muscle gives a coefficient of 1·79 to 2·01. The conductive process is therefore probably similar in both tissues, but doubt is expressed whether the high coefficient is a necessary proof of a chemical as opposed to a physical process. The coefficient for the latent period of muscle is 3·26 to 3·3; this strengthens the supposition that conduction in muscle is a propagation, not of the contractile change, but of an independent disturbance, which calls up the contractile change at each point on its passage.

W. D. H.

**Action of Nitrites and Atropine on Autonomic Nerves.**

Alfred Fröhlich and Otto Loewi (Arch. exp. Path. Pharm., 1908, 59, 34—56).—Certain autonomic nerves can be differentiated from those of sympathetic origin by their behaviour towards drugs, as shown in the following table:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Stimulated by</td>
<td>Paralysed by</td>

<tr>
<td>1. Autonomic</td>
<td>Pilocarpine</td>
<td>Atropine</td>
</tr>
<tr>
<td>2. Sympathetic</td>
<td>Adrenaline</td>
<td>Ergotoxin</td>
</tr>
</tbody>
</table>

48—2
These facts point to chemical differences in the nerve terminals.

W. D. H.

The Permeability of the Frog's Skin. WILLIAM M. BAYLISS (Biochem. Zeitsch., 1908, 11, 226—237).—The physical examination of the frog's skin in the living condition shows that its properties are not so clearly defined as those of the homogeneous membrane of the red corpuscles (Hamburger) or of muscle fibres (Overton). Its properties are only partly explicable on the hypothesis that it is a semi-permeable membrane. Its most interesting property is its irreciprocal permeability to sodium ions.

A New Function of the Pancreas and its Relation to Diabetes melitus. OTTO LOEWI (Arch. exp. Path. Pharm., 1908, 59, 83—94).—In normal men, cats, and dogs, adrenaline does not produce dilatation of the pupil, but this does take place in the following circumstances: (1) After total extirpation of the pancreas in dogs and cats; (2) in pancreatic insufficiency artificially produced in animals; (3) in many cases of human diabetes presumably of pancreatic origin; (4) in many cases of Basedow's disease.

It therefore appears that the pancreas has the power of inhibiting the sensitiveness to adrenaline in certain organs supplied by sympathetic nerves. In the last of the four cases, the susceptibility to adrenaline is possibly produced by hyperthyreodism. W. D. H.

Contraction of Striated Muscle. JOHN S. MACDONALD (Proc. physiol. Soc., 1908, xxv—xxvii; J. Physiol., 37).—An attempt to explain the contraction of muscle by supposing that electrolytes make their appearance in the dark bands which raise the osmotic pressure there, and so water is attracted from the light bands. This is supported to some extent by changes in the distribution of the potassium salts as determined by Macallum's reagent, but the process of relaxation is admittedly left unexplained.

W. D. H.

Non-striated Mammalian Muscle. TADASU SAIKI (J. Biol. Chem., 1908, 4, 483—496).—The non-striated muscle of the stomach and bladder is richer in water than striated muscle, and contains 2.8% to 3% of nitrogen. Traces of glycogen are present, and only 0.05% of lactic acid, although no precautions to avoid injury were taken. The creatine percentage is also low (0.8%); so is that of creatinine (0.024% to 0.052%). Hypoxanthine is the most abundant purine base; minute amounts of guanine and adenine are occasionally obtained, but never xanthine. The amount of haemoglobin is 0.13% to 0.3%, which is less than in blood-free striated muscle (1% to 2.3%). The amount of connective tissue is greater than in striated muscle. Sodium, iron, calcium, and chlorine are more abundant than in striated muscle; the opposite is true for other elements, potassium, magnesium, &c. There is about three times as much sodium as potassium. The influence of such ions on the manner of contraction is discussed. As much, or almost as much, of the soluble proteins were obtained twenty-four hours after removal in muscles kept at room temperature.
as in those kept in ice. No evidence of rigor mortis is therefore forthcoming. In spite of the low percentage of glycogen, evidence was obtained of its disappearance.

W. D. H.

Muscle Plasma. John Mellanby (Proc. physiol. Soc., 1908, xxxiv—xxxv; J. Physiol., 37).—Muscle plasma, prepared from bird's muscle, and containing 3% of added sodium chloride, clots on the addition of a little acid. This is prevented by dilution with water, but occurs immediately when more salt is added. It is soluble in excess of acid, but this is prevented by adding more salt. The coagulum produced by acid, when thoroughly washed, forms a gelatinous solution in water, which is acid to litmus, and is reprecipitated by small amounts of neutral salts. After careful precipitation of acid, the muscle plasma is practically free from protein.

Wide-reaching conclusions are drawn from these few experiments with salted muscle plasma to explain the coagulation of natural muscle plasma in rigor mortis. The combined action of salt and lactic acid is considered to cause rigor, and the development of more acid to produce its disappearance. The observations are also stated to indicate that there is only one protein in muscle, but in this preliminary communication no evidence is offered on this point.

W. D. H.

The Utilisation of Sugar during Muscular Activity. Johannes Müller (Chem. Zentr., 1908, i, 1567; from Zentr. Physiol., 1908, 21, 831—833).—The author has succeeded in isolating lactic acid from the perfusion liquid by means of the zinc salt. In spite of a sufficient oxygen supply, the amount of acid isolated corresponded with the amount of sugar utilised.

S. B. S.

Mono-amino-acids in Meat Extract. Karl Micko (Zeitsch. physiol. Chem., 1908, 56, 180—211).—Meat extracts contain a small and unimportant percentage of mono-amino-acids (alanine 0·23, glutamic acid 0·08, taurine 0·2%); there is also 0·36% of inosine. Dipeptides were not found.

W. D. H.

W. D. H.

Influence of Inorganic Colloids on Autolysis. IV. M. Ascoli and G. Izak (Biochem. Zeitsch., 1908, 10, 356—370. Compare this vol., ii, 121).—There is in the main an agreement between the action of colloidal silver on metabolism and on autolysis. Minimum amounts favour uric acid production. The uric acid-forming ferments are activated by colloidal silver, ferrous hydroxide, and arsenic sulphide. Larger amounts of the two last named inhibit uric acid formation. Uricolysis is delayed by colloidal silver; the other two colloids have no action on this phenomenon.

W. D. H.
The Autolytic and Hydrolytic Degradation of Protein under Normal and Pathological Conditions. W. GLIKIN and ADOLF LOEWY (Biochem. Zeitsch., 1908, 10, 498—505).—The tissues were allowed to autolyse for several days in toluene water until the action practically ceased. The ammonia-nitrogen, mono-amino-acid-nitrogen, and diamino-acid-nitrogen, both in the dissolved part and undissolved part of the tissue, were then determined. The same factors were also determined for a portion of the same tissues which had been directly hydrolysed without previous autolysis. Normal organs were examined (liver and muscular tissue), as well as those from animals which had been poisoned by hydrochloric and hydrocyanic acids. The autolysis of muscular tissue from animals poisoned by acids appears to be somewhat below the normal. The results, however, do not permit of any very definite conclusions being drawn.

S. B. S.

Available Alkali in the Ash of Human and Cows' Milk. JOSEPH H. KASTLE (Amer. J. Physiol., 1908, 22, 284—308).—Although the amount of ash in human milk is much less than in that of cows' milk, the amount of alkali as detected by phenolphthalein, and available for nutritive purposes, is the same. Numerous analyses are given, and various subjects in relation to milk in infant feeding are discussed at length. Among the points raised, the view is acquiesced in that much of the indigestibility of cows' milk in children is due, not so much to its protein constituents, as to excess of fat.

W. D. H.

Milk-serum. FR. LANDOLF (Biochem. Zeitsch., 1908, 10, 486—489).—Fractional examination of the osazones obtained from the serum of cows' milk leads to the conclusion, not that several modifications of lactose are present, but that lactose is united in part to other carbohydrates, and this factor modifies the polarisation, reduction power, fermentation, and the properties of the osazones. W. D. H.

The Ferment which Destroys Lactose in Milk. ALBERT J. J. VANDEVELDE (Biochem. Zeitsch., 1908, 11, 61—66).—Lactose is gradually destroyed in cow's milk when the latter has not been boiled. The reaction only takes place to a very slight extent in the presence of formaldehyde, but considerable change takes place when the milk is kept sterile by means of iodoacetone. Reducing compounds are formed which have not yet been isolated.

S. B. S.

The Excretion of Sulphurous Acid on the Human Subject after Administration of Sodium Sulphite and Sulphurous Acid in Combination with Sodium Salt. FR. FRANZ and G. SONNTAG (Chem. Zentr., 1908, i, 1477—1478; from Arb. K. Gesundh.-Amt., 1908, 28, 225—260).—Experiments were made to determine the form of excretion of sulphurous acid after administration of neutral sodium sulphite and formaldehyde, acetaldehyde, and dextrose sodium sulphites. Under certain conditions, sulphurous acid was obtained from the urine. This acid can be estimated by
oxidation to sulphuric acid by hydrogen peroxide. Care, however, must be taken in drawing conclusions as to the presence of sulphites in urine, as the latter on distillation yields sulphur compounds of unknown nature. In men, as in dogs, by far the greatest part of the injected sulphite is oxidised to sulphate. In certain cases, after intervals of ten minutes or a quarter of an hour, sulphites can be detected in the urine. The quantity was, however, never more than 1% of the sulphite administered.

S. B. S.

New Organo-mercury Compounds. "Iodoargyrum." Giulio Nardelli (Chem. Zentr., 1908, i, 1572; from Arch. Farm. Sperim., 1908, 7, 69—83).—The author finds that the mercury of this compound, $C_4H_4SHg_4I_4$ (Paolini, Abstr., 1907, i, 788), is passed in the urine in larger quantities than in the faeces. Taken in small doses, the iodine is passed in twenty-four hours, and the third constituent, thiophen, could not be detected in the urine; it appears to become changed in the system.

J. V. E.

Estimation of Reducing Substances in Infants' Urine. Roberto Funaro (Biochem. Zeitsch., 1908, 10, 463—466).—The total reduction in normal urine was estimated by Bang's method, the sugar by Bang's method, the uric acid by the Hopkins-Folin method, and the creatinine by Folin's method. After deducting the reduction due to sugar, uric acid, and creatinine, the remainder is due to isomaltose, dextrin, glycuronic acid, and unknown substances. Tables of analyses are given, and Larsson's conclusion is confirmed that infants' urine contains a smaller amount of all these substances than the urine of adult men and women.

W. D. H.

Amino-acids in the Urine during Pregnancy. E. C. van Leersum (Biochem. Zeitsch., 1908, 11, 121—136).—The main difficulty in Pfaundler's method of estimating the amino-acids in urine is the removal of the phosphotungstic salts. They can, however, be entirely removed by the addition of potassium chloride without any loss in the amino-acids taking place. The amino-acid nitrogen varies in health from 2.7 to 7.7% of the total nitrogen. It is increased by administering amino-acids. In pregnant women, it rises to over 10% in 40% of the cases, and the highest point is usually reached just before parturition; in some cases, it occurs after delivery; this may be related to the process of uterine involution.

W. D. H.

Origin of Endogenous Uric Acid. E. Provan Cathcart, E. L. Kennaway, and John B. Leathes (Quart. J. Med., 1908, 1, 416—446).—A marked increase in the output of endogenous uric acid is found to occur in three conditions: (a) fever: here the increased output coincides and terminates with the rise of temperature. (b) Exposure to cold. (c) After severe exertion. In the last two cases the increased output outlasts its cause by many hours.

The high output in the morning is not due to retention of uric acid formed during the night (as Hirschstein considers), or to inactivity of the digestive organs in the night (and it is doubtful if
such inactivity really occurs), but to the quickened activity of all functions, especially of voluntary muscles, which occurs after rest. The more lively the performance of the bodily functions the greater does the output of uric acid tend to be, and it is suggested that uric acid has its origin principally in the metabolic processes of the voluntary muscles. W. D. H.

Creatinine of Infants' Urine. **Roberto Funaro** (Biochem. Zeitsch., 1908, 10, 467—471).—Creatinine is always present in infants' urine. The individual differences are not great, even if the diet varies. The small amount present explains why those who used the zinc chloride method have been unable to detect it.

W. D. H.

Excretion of Pigments by the Urine. **Rudolf Höber and Felicia Kempner** (Biochem. Zeitsch., 1908; 11, 105—120).—If pigments insoluble in lipoids were injected intravenously in frogs, they were in part taken up by the kidney cells and excreted. Such pigments are acid magenta, aniline-blue, Congo-red, and many others. Other pigments were not taken up, such as Berlin-blue, benzoazurin, &c. The difference partly depends on how far the pigments are in colloidal solution; those which are not taken up being highly colloidal, but there are exceptions to this rule, for instance, Congo-red.

W. D. H.

Urinary Constituents Precipitable by Phenylhydrazine. **Hugo Milrath** (Zeitsch. physiol. Chem., 1908, 56, 126—134).—If dogs' urine is warmed for two hours on the water-bath with phenylhydrazine and acetic acid, phenylsemicarbazide is not obtained. Four to five hours' heating is necessary for the purpose, although cats' urine will sometimes yield the product in two hours. In the case of human urine, two to five hours is necessary, and in ten hours 80% of the urea is converted into phenylsemicarbazide. Aqueous solutions of urea yield similar results.

W. D. H.

Arnold's Urinary Reaction with Sodium Nitroprusside. **Theophil Holobut** (Zeitsch. physiol. Chem., 1908, 56, 117—125).—In people taking a meat diet, the urine gives a violet reaction with sodium nitroprusside and sodium hydroxide; this soon changes to purple, and finally yellow. If ammonia is used instead of sodium hydroxide, the colour lasts longer. The same coloration is obtained with dogs' urine when the animals are fed on cooked meat, cheese, eggs, and other protein-rich food, but not when they are fed on raw flesh, gelatin, or vegetable albumin.

W. D. H.

Molecular Concentration of Pathological Fluids. **Adolphe Javal** (Compt. rend., 1908, 146, 1328—1330).—Hypoconcentration is relatively rare; hyperconcentration is fairly frequent in disease, especially in cases of cardiorenal insufficiency. This is mainly due to salts, and estimations of the amount of sodium chloride in different
fluids of the body are given. The increase of concentration is increased in some cases by the retention of nitrogenous catabolites.

W. D. H.

The Chemical Test for Diseases due to Nerve Degeneration. The Formation of Alkylamines. Koloman Bauer (Beitr. chem. Physiol. Path., 1908, 11, 502—514).—Concentrated urine was, after certain preliminary treatment, made alkaline, and the bases distilled over with steam into acid. The solution of the salts thus obtained was evaporated down and the residue treated with sodium hypobromite, whereby ammonia and primary and secondary bases were destroyed. The tertiary base trimethylamine was then distilled over with steam and isolated in the form of its platinichloride.

It was found that trimethylamine was a constant constituent of normal urine, due to the normal degradation of lecithin substances. Substances containing a choline complex, such as eggs and meat, added to the diet, caused an increase in trimethylamine elimination. The normal output of trimethylamine with a mixed diet is 18 to 26 mg. per day for an adult man. The base was also estimated in several cases of nervous disease. The average quantities found were: 51 mg. daily in the cases of tabes, 59 mg. in myelitis, and 37 mg. in progressive paralysis. In one case of neurasthenia, the amount of trimethylamine found gave no evidence of destruction of nervous matter, whereas in a second case it did.

S. B. S.

Protein Metabolism in Cystinuria. Charles G. L. Wolf, Philip A. Shaffer [with Emil Osterberg and Michael Somogyi] (J. Biol. Chem., 1908, 4, 439—472).—The anomalies of metabolism in cystinuria consist in low ammonia, high undetermined nitrogen, and high neutral sulphur in the urine. The high undetermined nitrogen is partly, and the high neutral sulphur wholly, due to cystine. The ingestion of protein in a cystinuric person increases the neutral sulphur, and so presumably increases the cystine in the urine. If cystine or cysteine is given by the mouth, they are completely broken down to sulphates; it must, therefore, be assumed that the cystine group of the protein is not absorbed as such, but in combination as polypeptide or thio-protose. These appear to be different types of cystinuria, but it is only in the more severe cases that tolerance for cystine or other amino-acids is diminished. If cystine is given subcutaneously, it is partly oxidised and partly excreted in the urine, but no controls were made on healthy people. Sulphur-free amino-acids are almost quantitatively catabolised to urea. Sodium cholate does not increase the cystine excreted. With regard to the time relations of the excretion after protein-feeding, no standards of comparison in normal persons are at present available. In the cystinuric patients, the maximum of nitrogen excretion occurred later than that of carbon, and the former was coincident with that of sulphur. The maximum excretion of ammonia was early. The curves for neutral sulphur and undetermined nitrogen were approximately parallel. The relationships of cystinuria to bile secretion are discussed, but without any very clear conclusions. In cases of cystinuria in which the excretion of cystine
stops from time to time, the sulphur of the urino returns to normal for these periods, but the undetermined nitrogen remains high on many days; this is possibly due to amino-acids.

W. D. H.

—The results and figures given appear to show that with a prolonged and increasing acidosis in severe diabetes, a point is reached in which increased ventilation of the lungs occurs, which leads to a decrease of the carbon dioxide in the alveolar air and blood, notwithstanding that the blood is still capable, in spite of its reduced alkalinity, of taking up large quantities of carbon dioxide. The increased respiration is ascribed to the stimulation of the respiratory centre by acid substances, including carbon dioxide and other acids produced by metabolism, and prolonged acidosis appears to increase the sensitiveness of the centre.

W. D. H.

Influence of Diuretics on Phloridzin Diabetes. Otto Loewi and E. Neubauer (Arch. exp. Path. Pharm., 1908, 59, 57—63).—In contrast with other diuretics, the addition of sodium chloride does not increase the diuretic action of phloridzin, neither is the amount of sugar excreted increased by the administration of diuretics.

W. D. H.

Influence of Calcium on Diuresis. Otto Porges and Egon Pribram (Arch. exp. Path. Pharm., 1908, 59, 30—33).—If calcium chloride is introduced into the blood stream, its diuretic action is about equal to that of sodium chloride, unless doses sufficiently large to lower the blood pressure are given.

W. D. H.

Physico-chemical Considerations as to the Pharmacological and Toxicological Actions of Mercury. Luigi Sabbatini (Biochem. Zeitsch., 1908, 11, 294—310).—The toxic effects of mercury on higher animals, just as in the case of bacteria, as shown by Krönig and Paul, depend on the concentration of mercury ions. Thus, by intravenous injection of sodium chloride, bromide, or iodide before the mercuric chloride, the toxic effect of the latter is depressed, owing to its decreased dissociation due to the presence of the sodium salts. The iodide is more effective than the bromide, and the bromide than the chloride, the iodide and bromide of mercury both dissociating less than the chloride. The lesions due to mercury poisoning can also be explained by the concentration of the mercury ions. These lesions occur chiefly in the secretory and excretory tracts. The concentration of the ions in the saliva, for example, would be great, owing to the absence of chlorides and proteins. In the stomach, on the other hand, the presence of chlorides and of protein would depress the dissociation of the chlorides; here the disturbance in mercury poisoning would be small. In the small intestine, the chlorides and peptones are still in large quantity, and again the dissociation would be small. Still lower in the intestinal tract, owing to absorption of chlorides and products.
of tryptic digestion, the dissociation of mercury salts would be greater, and therefore the toxic effects can be observed. The lesions in the kidneys themselves, due to mercuric poisoning, occur almost exclusively in the convoluted tubules. Here, according to the Ludwig hypothesis, the urine is dilute, and becomes gradually concentrated in the passages, and here, also, the dissociation of the mercury salt and concentration of the ions can be great: hence the lesions.

S. B. S.

The Degradation of Carboxylic Acids in the Animal Body. VII. The Formation of Acetoacetic Acid from \textit{iso}Valeric Acid by Perfusion through the Liver. \textit{Ernst Friedmann} (\textit{Beitr. chem. Physiol. Path.}, 1908, 11, 365—470. Compare this vol., i, 421; ii, 205).—Embeden has shown that \textit{iso}valeric acid is converted into acetoacetic acid by perfusion through the surviving liver:

\[
\text{CHMe}_3\cdot\text{CH}_2\cdot\text{CO}_2\text{H} \rightarrow \text{CH}_3\cdot\text{CO}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}.
\]

To determine the mechanism of the reaction, perfusion experiments were carried out with the following acids. \textit{iso}Valeric acid, \textit{a} hydroxy-\textit{iso}valeric acid, \textit{b} hydroxy\textit{iso}valeric acid, pyrotartaric acid, and citramalic acid. Of these, only \textit{iso}valeric acid and the \textit{b} hydroxy-derivative lead to the formation of acetone (and acetoacetic acid). From these results, the conclusion is drawn that the secondary carbon atom offers the first point of attack, and that the methyl group is not first oxidised.

S. B. S.

The Degradation of Carboxylic Acids in the Animal Body. VIII. The Behaviour of \textit{a\textit{b}} Unsaturated Acids when Perfused through the Liver. \textit{Ernst Friedmann} (\textit{Beitr. chem. Physiol. Path.}, 1908, 11, 371—375).—Both dimethylacrylic and crotonic acids give rise to acetone by perfusion through the liver, whereas citraconic and mesaconic acids do not. The methyl group here does not offer the first point of attack, but the chemical change can be best explained by assuming that the addition of the elements of water at the double linking first takes place with the formation of \textit{b} hydroxy-acids. Dimethylacrylic acid, according to this hypothesis, would be converted into \textit{b} hydroxy\textit{iso}valeric acid, which readily gives rise to acetone (compare preceding abstract).

S. B. S.

Degradation of Carboxylic Acids in the Animal Body. \textit{Henry D. Dakin} (\textit{Beitr. chem. Physiol. Path.}, 1908, 11, 404—405).—Friedmann has claimed (see this vol., ii, 205, and also preceding abstracts) that, on degradation of carboxylic acids, oxidation takes place first at the \textit{b} carbon atom with the formation of \textit{b} hydroxy-compounds. To this Knoop has objected, claiming that in normal fatty acids, oxidation generally takes place at the \textit{a} position, and that the formation of \textit{b} hydroxy-derivatives is an indirect process. Dakin, in support of Friedmann, shows, however, that \textit{n} butyric acid can yield acetone to the extent of 50\% of the theoretical quantity when oxidised by hydrogen peroxide. This reaction can be best explained on the assumption that a \textit{b} hydroxy-derivative is first formed. Furthermore, all other fatty acids of the same series, up to stearic
acid, undergo a similar oxidation. Octoic acid yields methyl n-amyl ketone; lauric acid, methyl n-nonyl ketone, and stearic acid, methyl n-pentadecyl ketone. The reactions may be represented as follows:
\[ R \cdot CH_2 \cdot CH_2 \cdot CO_2H \rightarrow R \cdot CH(OH) \cdot CH_2 \cdot CO_2H \rightarrow R \cdot CO \cdot CH_2 \cdot CO_2H \rightarrow R \cdot CO \cdot CH_3. \]

Further, phenylpropionic acid, when administered to an animal, yields, in addition to hippuric acid, \( \beta \)-hydroxyphenylpropionic acid and acetophenone, another example of \( \beta \)-oxidation. The reaction also takes place in vivo when hydrogen peroxide is employed as the oxidising reagent (see below).

S. B. S.

The Oxidation of Fatty Acids. FRANZ KNOOP (Beitr. chem. Physiol. Path., 1908, 11, 411—414).—Reply to Friedmann on question of "\( \beta \)-oxidation" (see preceding abstracts of Friedmann and Dakin).

S. B. S.

Oxidation of Phenyl Derivatives of Fatty Acids by the Animal Organism and by Hydrogen Peroxide. HENRY D. DAKIN (J. Biol. Chem., 1908, 4, 419—435).—After hypodermic injection, \( \beta \)-phenylpropionic acid is broken down in dogs to
\[ OH \cdot CH \cdot Ph \cdot CH_2 \cdot CO_2H, \]
\[ CO \cdot Ph \cdot CH_2 \cdot CO_2H, \]
\[ CO \cdot PhMe, \]
and \( \text{PhCO}_2\text{H} \), the last substance occurring in the urine as hippuric acid. \( \beta \)-Hydroxy-\( \beta \)-phenylpropionic acid occurs as the laevorotatory variety, in close analogy to \( l \)-\( \beta \)-hydroxybutyric acid. Benzoylecetic acid could not be isolated, but its production is inferred from the occurrence of acetophenone in the urine.

The oxidation of \( \beta \)-phenylpropionic acid and of \( \beta \)-hydroxy-\( \beta \)-phenylpropionic acid by hydrogen peroxide is very similar, acetophenone and benzoic acid being produced; the oxidation proceeds slowly even at 37°.

In order to test the hypothesis that phenylacetic acid owes its resistance to oxidation to its combination with glycine, \( \beta \)-phenylpropionylglycine, \( CH_2 \cdot Ph \cdot CH_2 \cdot CO \cdot NH \cdot CH_2 \cdot CO_2H \) (thick needles, m. p. 114—115°, more soluble in water than hippuric acid) was synthesised. After administration to dogs, it yields, however, the same degradation products as phenylpropionic acid.

G. B.

[Physiological] Action of Optical Isomerides. III. Adrenaline. ARTHUR R. CUSHNY (J. Physiol., 1908, 37, 130—138).—Neutral or \( l \)-adrenaline acts twice as strongly on the blood pressure as synthetic or \( r \)-adrenaline, and presumably also on the other organs affected by adrenaline. From this it is inferred that \( d \)-adrenaline is devoid of action on these tissues, and this was confirmed by the examination of a partly isolated \( d \)-adrenaline.

W. D. H.

Action of the Digitalis Group on the Kidneys. D. JONESCU and OTTO LOEWI (Arch. exp. Path. Pharmac., 1908, 59, 71—82).—Substances of the digitalis group act as diuretics in doses insufficient to raise the blood pressure. They act by dilating the renal blood-vessels, and this is a specific effect on these vessels.

W. D. H.
The Action of Strychnine on the Nerve Fibres of the Vagus to the Heart. V. FORLI (Chem. Zentr., 1908, i, 1568; from Zentr. Physiol., 1908, 21, 823—827).—Strychnine sulphate solution was allowed to act on the nerve fibres of the vagus of the heart in a cat; a diminution of conductivity and irritability of the affected position was observed, analogous to the action of the same substance on the sympathetic nerve fibres in the neck.

S. B. S.

Sulphurous Acid in its Biochemical Relationship. Leo GRÜHNUT (Biochem. Zeitsch., 1908, 11, 89—104).—Theoretical considerations are advanced as to the reason of the comparative toxicity of various solutions of sulphites, and compounds with salts of sulphites. The conclusion is drawn that the specific toxicity of a given sulphite solution depends on the quantity of \( \text{H}_2\text{SO}_4 + \text{SO}_2 \) contained therein.

Chemistry of Phosphorus Poisoning. OTTO FORGES and ÉCON PIBRARD (Arch. exp. Path. Pharm., 1908, 59, 20—29).—In the phosphorus liver, a smaller part of the nitrogen is in the form of protein than in the normal liver. The lessening of hexone bases is still more marked. On autolysis, the nitrogen contained in substances precipitable by tannin is much greater than in autolysis of the normal liver. The nitrogen split off by hydrochloric acid is raised from 10% (the normal number) to 13%. How far these changes are due to differences in ferment action is discussed.

W. D. H.

The Supposed Antidotes to Alkaloids and Artificial Antitoxins. H. DORLENCOURT (Chem. Zentr., 1908, i, 1568; from Bull. Sci. Pharm., 1908, 15, 82—88).—The statement of Baudran that antitoxins to alkaloids can be prepared by treating the latter with calcium permanganate was submitted to experimental investigation. It was found that a lethal dose of strychnine, injected intra-muscularly together with the substance produced by the action of calcium permanganate on the alkaloid, produced no toxic action. Heating the mixture to 120° produced no change in its action, and it was found that manganese salts, such as the chloride, act as an antidote to strychnine. There is, therefore, no question of a specific antitoxin. Similar results were obtained by intra-cerebralar as by intra-muscular injections, and it is suggested that manganese salts might be employed as antidotes in therapeutic practice.

S. B. S.

Cobra Poisoning and Hæmolysis. IVAR BANG (Biochem. Zeitsch., 1908, 11, 520—537).—The importance of lecithin in cobra poisoning, as advanced by Kyes and others, is denied, and the existence of cobra-lecithid considered unproved. Kyes' cobra-lecithid is not a pure substance; it may be a mixture of poison and activator, or a chemical combination, but it is quite uncertain what the activator is; the mixture contains decomposition products of phosphatides, fats, and soaps. Lecithin itself, prepared from egg-yolk, was found to be wholly inactive as an activator to cobra venom in producing hæmolysis; the same is true for the monoamino-
ABSTRACTS

phosphatide, cuorine, and the diaminophosphatide of egg-yolk. The kephalin fraction was found to be active, but the exact composition of this fraction is uncertain. Kossel's protagon, which consists largely of kephalin, is, however, inactive.  

W. D. H.

Chemistry of Vegetable Physiology and Agriculture.

The Action of the Zinc Ion on Media for Microbes. Joseph Mendel (Compt. rend., 1908, 146, 1290—1291).—Two electrodes, one of zinc and the other of platinum, were introduced into an infected gelatin tube, and a current of 1—5 milliamperes was passed through the medium for some minutes. An opaque zone developed round the zinc electrode, and the bacteria with which the medium had been infected grew well everywhere, except within this zone. S. B. S.

Gerlach and Vogel’s statement (Centr. Bakt. Par., ii, 10, 636) to the opposite effect is due to the fact that small amounts of potassium salts were always present in the media used in these experiments.

Formation of Acid by the Diphtheria Bacillus. C. Lubenaau (Arch. Hygiene, 1908, 66, 305—335).—The production of acid by Löffler's bacillus depends (as is well known) on the presence of carbohydrates in the broth; when the latter is free from carbohydrates, alkali is produced, but only under aerobic conditions. Diphtheroid organisms produce less acid on the whole, and do not form appreciable quantities of alkali. True diphtheria bacilli may produce acid, even in the absence of carbohydrates, if grown in a bouillon in which the proteins have been partly decomposed by a fourteen days' growth of Bacillus coli; the acid seems to be derived from the proteins. The addition of glycerol to the culture medium causes the diphtheria bacillus to accelerate its production of acid in the first few days, whilst in the case of diphtheroid organisms the acceleration does not occur until later.

G. B.

Part Played by Yeasts in the Aldehydification of Alcohol. J. Auguste Trillat and Sauton (Compt. rend., 1908, 147, 77—80. Compare this vol., ii, 615).—Previous experiments have shown that living yeasts have a greater effect in the formation of aldehyde than yeasts sterilised by heat. Repetition of these experiments, in which the yeast was killed by antiseptics, gave similar results. Thus, living
yeast gave 1100 mg. of aldehyde per 100 grams of alcohol, yeast killed by mercuric chloride gave no aldehyde, that killed by formaldehyde gave traces, whilst after sterilisation by heating at 120°, by means of salicylic acid, and by sodium fluoride, less than 100 mg. of aldehyde were formed. Moreover, increase in the proportion of alcohol present lowers the yield of aldehyde, the alcohol acting as an antiseptic. When yeast cells are killed by the action of chloroform and shaken with 10% alcohol, only traces of aldehyde are produced, and the clear filtrate produced when yeast is crushed in a Borrel apparatus is similarly inactive. If ethyl alcohol is replaced by methyl, propyl, butyl, isobutyl, or amyyl alcohol, the corresponding aldehyde is never formed. The proportions of aldehyde and ethyl acetate formed depend on the duration of the experiment; thus immediately after agitation, 1100 mg. of aldehyde, but no ethyl acetate, were found, whereas after four days the amount of acetate was 316 mg., and of aldehyde less than 100 mg. This is probably to be explained by the formation of ethyl acetate from the acetic acid resulting from the oxidation of the aldehyde (compare Kayser and Demolon, Abstr., 1907, ii, 714; this vol., i, 317). It is found, also, that yeasts accelerate the production of ethyl acetate in a solution of alcohol and acetic acid.

The rapid disappearance of the aldehyde previously described occurs only under the influence of living, not of dead, yeasts.

The conclusions are drawn that the production of aldehyde reaches its maximum in presence of the living yeast cell, that it is not effected by the juice contained in the cell, and that the phenomenon is peculiar to ethyl alcohol.

E. H.

Malic Acid in the Production of Wine. Malo-lactic Fermentations. W. Mestrezaht (J. Pharm. Chim., 1908, [vi], 28, 13—20. Compare Abstr., 1907, ii, 903). —The malic acid of grape-juice partly disappears during fermentation, but no lactic acid is formed, and the "malo-lactic" fermentation of Rosenstiehl (Rev. viticole, 29, 509) does not exist. During the ripening of the wine, the malic acid undergoes a further slight diminution.

G. B.

The Depression of Fusel Oil Formation, and the Part Played by Bacteria in the Formation of the Higher Alcohols during Fermentation. Hans Pringsheim (Biochem. Zeitsch., 1908, 10, 490—497).—If ammonium sulphate is added as a source of nitrogen, the amount of amyl alcohol formed from leucine is diminished. The addition of 500 and 1000 grams of the sulphate to 2000 litres of mash, diminished the fusel oil yield from 5 to 2 litres; the addition of 250 grams of salt caused a diminution to 2·5 litres. In the fusel oil, n-butyl alcohol was found in very appreciable quantities when ammonium sulphate was added to the mash. In the fusel oil obtained when this addition was not made, isopropyl alcohol was found. These alcohols are probably due to the action of bacteria.

S. B. S.

Transformation of Starch in Plants. Wl. Butkewitsch (Biochem. Zeitsch., 1908, 10, 314—344).—The change of starch into sugar which is carried out by bark and wood is due to ferment action,
and the diastase was obtained in concentrated form by precipitation of aqueous extracts with alcohol. The bark also inverts maltose. Various conditions, such as changes of temperature on the activity of the ferments, are described.

W. D. H.

The Hydrolytic and Catalytic Ferments Acting during the Process of Ripening of Fruit. Giuseppe Tallarico (Chem. Zentr., 1908, i, 1563—1564; from Arch. Farm. sperin., 1908, 7, 27—48).—

Bananas were employed for the study; from this fruit, gathered in different stages of ripening, extracts were made. The catalytic action was determined by investigating the action of the extract on hydrogen peroxide; the amylolytic, by its action on starch; the proteolytic, by the action on gelatin, and the inverting, by the action on sucrose. The following enzymes were present: catalase, invertase, amylase, tyrosinase, and a proteolytic enzyme. The catalytic action is very intense so long as the fruit is green and during ripening; it weakens as the fruit gets black. The amylolytic action takes place when the fruit is green or at the beginning of the stage of ripening; it then disappears. The inverting action is almost entirely absent during the green stage, is intense during ripening, and then gradually disappears. The proteolytic action manifests itself during ripening, and then probably gets weaker.

S. B. S.

Carrotene from Carrots and the Substances which accompany it. Hans Euler and Ebba Nordenson (Zeitsch. physiol. Chem., 1908, 56, 223—235. Compare Willstätter, Abstr., 1907, i, 865; Arnaud Abstr., 1885, 670; 1886, 711; 1887, 859).—When fresh carrots are ground with sand, it is found that the expressed juice contains only a portion of the carrotene. The following substances have been extracted from carrots (23 kilos.): Phosphatides, lecithin, &c., 13; daucosterol, 0·5; phylosterol, 1·3; carrotene and xanthophyll, 0·7; oil of unknown composition, 3·5 grams. The following method of extraction is recommended: Boil with water, press, dry in absence of air, extract with carbon disulphide, and then with alcohol. Distil, dissolve in small amount of light petroleum, and precipitate the phosphatides with alcohol. The carrotene and xanthophyll can be thrown down by the addition of suitable salts to the solution, and can be separated with Willstätter's method.

Daucosterol, C_{29}H_{49}O_{4} (I), crystallises from boiling alcohol in flocculent masses consisting of microscopic needles, m. p. 283°, and gives the Salkowski-Hesse reaction.

An analysis of the purified phosphatides gave the ratio N : P = 1 : 0·6.

When carotene is oxidised with a small amount of an acetic acid solution of chromic anhydride, care being taken that the temperature does not rise above 30—40°, an oil, C_{40}H_{56}O_{8} or C_{40}H_{60}O_{9}, which does not solidify at −10° is obtained. Phytosterol was not obtained when the carotene employed was quite free from this compound.

J. J. S.

The Endo- and Ekto-invertase of the Date. A. E. Vinson (J. Amer. Chem. Soc., 1908, 30, [vi], 1005).—The invertase of the date remains insoluble in all ordinary solvents throughout the green stages,
but becomes readily soluble on ripening, that is, it changes from an endo- to an ekto-form. The change in the behaviour of the invertase towards solvents coincides very closely in point of time with the passage of the tannin into the insoluble form. Evidence is, however, adduced to show that the two phenomena are not causally connected; thus glycerol will dissolve date invertase in presence of soluble tannin, but it fails to extract invertase from green dates. Tannin, however, renders invertase insoluble in water. It does not appear that the invertase is altered in changing from the insoluble to the soluble form. The rates of inversion of sucrose by equivalent amounts of green and of ripe date pulp are practically identical. Picric acid, chromic acid, and formaldehyde retard the action of green and ripe pulp to approximately the same degree. The living protoplasm does not appear to be directly connected with the inversion, since neither ether, chloroform, nor acetone render inactive the green tissue.

The author explains the difference in solubility by supposing that in the case of the green date the enzyme forms an insoluble compound with some constituent of the protoplasm; on ripening, the protoplasm undergoes profound change, and the enzyme is liberated. He examines and rejects the alternative view, that the cell wall of the green tissue is semi-permeable, whilst that of the ripe tissue is not. E. J. R.

Transitory Presence of Hydrogen Cyanide in Ferns. Maurits Greshoff (Pharm. Weekblad, 1908, 45, 770—773).—The author has detected hydrogen cyanide in ferns, such as Gymnogramme aurea, G. lastrea, and G. athyrium. The percentage varied between 0·056 in very young fronds and 0·006 in old fronds, and always diminished with increase in the age of the material examined. A. J. W.

Chemical Examination of Ipomoea purpurea. Frederick B. Power and Harold Rogerson (Amer. J. Pharm., 1908, 80, 251—286).—The chief constituent dissolved by alcohol is a resin, from which by extraction with various solvents the following substances were obtained: pentatriacontane, a phytosterol (C27H45O, m. p. 132—133°, $[\alpha]_D -32·1^\circ$, probably identical with sitosterol; compare Abstr., 1903, ii, 517), several fatty acids, a new crystalline alcohol, ipuranol, $C_{22}H_{33}O_3(OH)_2$, m. p. 285—290°, and a new acid, termed ipurolic acid, $C_{18}H_{25}(OH)_2\cdot CO_2H$, silky needles, m. p. 100—101°.

Ipuranol yields an acetyl derivative, m. p. 160° (not analysed); from the acid, the sodium salt, $C_{18}H_{25}(OH)_2\cdot CO_2Na\cdot H_2O$, the silver salt (m. p. 160°), the methyl ester, $C_{18}H_{25}(OH)_2\cdot CO_2Me$, m. p. 68—69°, the monomethyl ether of methyl ipurolate, OH·$C_{18}H_{25}(OMe)\cdot CO_2Me$, m. p. 64—65°, and the diphenylurethane of methyl ipurolate, $C_{18}H_{25}(O\cdot CO\cdot NHPh)_2\cdot CO_2Me$, m. p. 96—97°, were prepared. By decomposition of the various resin fractions with potassium hydroxide and with barium hydroxide, there were obtained a number of acids, including a-methylbutyric acid, $[\alpha]_D +17·95^\circ$, $\alpha$-hydroxylauric acid, $C_{12}H_{24}O_8$, m. p. 69—70°, and probably azelaic acid. The drug also contains a minute quantity of an essential oil.

G. B.

Vol. xciv. ii. 49
"Bourgou" (Panicum stagninum); a Sacchariferous Grass. E. Perrot and Eugène Tassilly (Bull. Soc. chim., 1908, [iv], 3, 740—742).—A sample of this grass collected in Upper Senegal was found to contain 10% of sucrose, 7% of reducing sugars, calculated as dextrose, some emulsin, but no invertase or glucosides capable of being hydrolysed by emulsin.

T. A. H.

Influence of Manures and Soil Moisture on the Disposition and Perfection of the Ears and the Club Shape of Göttingen Square-head Winter Wheat. W. Ohlmer (J. Landw., 1908, 58, 153—171; from Inaug. Diss. Göttingen, 1907).—The wheat was grown in zinc vessels and pots containing loam, with different manures; the amounts of water were 45% and 70% of the water capacity of the soil.

It is shown that the club shape becomes more marked when the nitrogen supply is increased, whilst a high percentage of moisture in the soil is unfavourable.

N. H. J. M.

The Storage and Transportation of Sucrose in the Beet (Beta vulgaris). Friedrich Strohmer (Chem. Zentr., 1908, 1, 1469—1470; from Oesterr.-ung. Zeitsch. Zuckerind. Landw., 37, 18—21).—In the second year of growth, at the time of flowering, the cane sugar disappears from the roots, and is employed for building up the parts of the plant above the earth. At this time, both in the main stem and in the branches, more invert sugar is found than sucrose, so that hydrolysis into monosaccharides of the latter first takes place, when it is transported, the hydrolysis being followed by re-synthesis. The exposure to light has great influence on the store of sugar; plants which have been kept in the shade half the day during the whole period of growth yield only one-fourth to one-half as much sugar as those which, growing under otherwise similar conditions, have been exposed to full light for the whole day. The plants grown in the shade yielded larger quantities of other products of non-carbohydrate nature, and had consequently considerably less technical value.

S. B. S.

Manuring Experiments with Calcium Cyanamide for Potatoes. Albert Stutzer (J. Landw., 1908, 56, 141—144).—The potatoes were grown on plots of 100 square metres, without nitrogenous manure, and with 250, 500, and 750 grams of sodium nitrate, "Stickstoffkalk," and ammonium sulphate respectively. Sodium nitrate gave lower yields than "Stickstoffkalk," probably owing to the large amount of rain; the percentage of starch was, however, highest when sodium nitrate was employed. The highest yields per acre of dry matter and starch were obtained on the plot which received 500 grams of "Stickstoffkalk."

N. H. J. M.

[Nutritive Value of Non-Proteins in Hay.] Max Müller (J. Landw., 1908, 56, 192—193. Compare this vol., ii, 220).—The hay extract employed in the feeding experiments previously described (Abstr., 1907, ii, 645) contained 1·87% total N by Jodlbaur's method
PERSISTENCE OF THE NITROGEN OF GREEN MANURE IN A LIGHT SANDY SOIL. CONRAD VON SEELHORST (Mitt. deut. landw. Ges., 1908, 23, 83—89, 139—144).—Experiments with different plants grown with green manures in a sandy soil in iron boxes having an area of 1 square metre. The nitrogen in the crops was determined, and also the amount per month and nitrogen content of the drainage. The experiments commenced in 1904 (compare ibid., 1906, 21, 289—292, 295—299).

The decomposition of green manure in sandy soil is so rapid that, when applied in October, half the nitrogen may be washed out in the drainage by February or March when the winter has been mild and wet. When applied in February, the decomposition would be still more rapid; the loss of nitrogen is then, however, reduced partly by its being taken up by the growing crop and partly by the amount of drainage being diminished.

The amount of nitrogen was determined in the rain collected in Göttingen in 1906, and the following results obtained:

The rainfall for the year was 771-8 mm., and the total nitrogen 8718 kilos. per hectare, or 1-13 per million of rain water.

ACTION OF ORGANIC NITROGEN MANURES AS COMPARED WITH SODIUM NITRATE. MAX POPP (Landw. Versuchs-Stat., 1908, 68, 253—300).—Blood meal and horn meal in quantities containing (1) 0-2 and (2) 0-4 gram of nitrogen in each case were mixed with soil (250 grams), and the amounts of nitrogen as ammonia and nitrates determined in water extracts at the commencement and after two, six, and twelve weeks. The following amounts of nitric nitrogen, as percentages of total N, were found:

<table>
<thead>
<tr>
<th>At commencement.</th>
<th>2 weeks.</th>
<th>6 weeks.</th>
<th>12 weeks.</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

The amounts of ammonia were very small, except after two weeks, when the nitrogen in that form amounted to 6—13%. Similar experiments, in which calcium carbonate was also added, generally gave very slightly higher results.

Vegetation experiments extending over five or six years are...
described, in which different crops were grown successively in large cylinders and manured with a variety of organic manures. The approximate values of the different manures as compared with sodium nitrate were found to be as follows: blood meal and horn meal, 70; fish meal, ricinus meal, and meat meal, 60; Bremer poudrette and bone meal, 55; molasses manure, 40; wool dust, 25, and leather meal, 10.

N. H. J. M.

Gaseous Compounds produced by the Decomposition of Calcium Cyanamide and their Action on Plant Growth. Emil Haselhoff (Landw. Versuchs-Stat., 1908, 68, 189—228).—Calcium cyanamide mixed with soil and basalt sand gave off 3.78 and 4.26% of the total nitrogen as ammonia in eight days. In three days, 50 grams of the manure yielded 0.00068 gram of hydrogen phosphide, but no hydrogen sulphide, and in the same length of time 10 grams gave 0.0795% of acetylene.

Results of experiments on germination in presence of the different gases make it probable that the injurious action of calcium cyanamide is due to free ammonia and perhaps also to hydrogen phosphide. Acetylene was found to have no injurious action on germination.

Experiments were also made in soil and water culture on the action of the different gases. The results showed that small amounts of free ammonia, hydrogen phosphide, and hydrogen sulphide are injurious to growth.

N. H. J. M.

Absorption of Calcium Cyanamide in Soil. Hubert Kappen (Landw. Versuchs-Stat., 1908, 68, 301—331).—The absorptive power of soils causes the decomposition of calcium cyanamide into lime and cyanamide. The latter compound is also produced by the action of carbon dioxide, and its production is rapid when both actions occur simultaneously. The formation of cyanamide is favourable to vegetation, since it is more readily attacked by bacteria than the strongly alkaline calcium compound.

In soils of low absorptive power, the transformation of calcium cyanamide is slower, and, under these conditions, injury to germination and plant growth, due to poisonous cyanamide compounds, may occur.

The influence of absorption is only indirect, conditions being produced which are favourable to the rapid conversion of poisonous compounds into harmless substances.

N. H. J. M.

Factors which Influence the Manurial Action of Sparingly Soluble Phosphates. Henrik G. Söderbaum (Landw. Versuchs-Stat., 1908, 68, 433—450).—Oats and barley were grown in pots in a sandy soil, deficient in nitrogen and phosphoric acid, manured with different phosphates in conjunction with nitrogen in different forms.

Oats manured with tricalcium phosphate gave slightly lower results with ammonium nitrate and slightly higher results with ammonium sulphate than when sodium nitrate was employed. In the case of barley manured with bone meal, ammonium nitrate caused a similar depression as compared with sodium nitrate, whilst ammonium sulphate
reduced the yield 46·6%. A mixture of sodium nitrate and ammonium sulphate, however, increased the yield (4·1%) as compared with sodium nitrate alone. Tricalcium phosphate, ammonium sulphate, and potassium sulphate gave somewhat higher results (with oats) than when potassium chloride was employed, whilst bone meal, ammonium sulphate, and potassium chloride gave distinctly better results (with barley) than when potassium sulphate was used.

In a subsequent series of experiments, ammonium salts (both nitrate and sulphate) in conjunction with tricalcium phosphate and bone meal respectively considerably increased the yield of oats as compared with sodium nitrate. Barley manured with bone meal and ammonium nitrate gave higher results than with sodium nitrate, whilst tricalcium phosphate and ammonium nitrate gave lower results. Both phosphatic manures (especially tricalcium phosphate) gave much lower results with ammonium sulphate than with sodium nitrate. Addition of equivalent amounts of sodium carbonate to ammonium sulphate in conjunction with bone meal increased the yield of barley, the total produce being then slightly higher (1·1%) than with sodium nitrate and bone meal. In the case of tricalcium phosphate, addition of sodium carbonate with ammonium sulphate nearly doubled the yield obtained with ammonium sulphate and tricalcium phosphate; the yield, however, was still more than 50% below that obtained with sodium nitrate and tricalcium phosphate.

Sodium carbonate in conjunction with ammonium sulphate and phosphates very slightly reduced the yield of oats as compared with ammonium sulphate and phosphates alone.

The changes in the physiological reaction caused by different nitrogenous compounds will not only vary with different plants, soils, and with different amounts and kinds of the other manures employed, but may even be reversed.

---

Analytical Chemistry.

Absorption Bulbs for use with Bottles containing Standard Solutions, &c. M. Emmanuel Pozzi-Escot (Bull. Assoc. chim. Surr. Dist., 1908, 25, 1077).—A piece of apparatus is described which may be fitted to bottles containing standardised alkali solutions in order to prevent the entrance of carbon dioxide, &c., to the bottle when the solution is drawn off into a burette. It consists of a bulb provided with a side-tube reaching to the bottom of the bulb; the air enters by this tube and, after bubbling through potassium hydroxide solution or other absorbent placed in the bulb, leaves through a tube at the top of the bulb. This tube is bent downwards so that it can be fixed through a hole in the cork of the bottle. By slightly altering its form, the bulb may be used to absorb the gases formed during fermentation experiments, and for other purposes.

W. P. S.

50—2
Replacement of Hydrogen Sulphide in Chemical Analysis. Eduard Donath (Chem. Zeit., 1908, 32, 629—630, 645—647).—The author recommends the process used by Vortmann chiefly on hygienic grounds.

This process is, briefly, as follows: the solution is made alkaline with sodium hydroxide and then heated with excess of pure sodium sulphide, which dissolves the metals of the tin group. The insoluble matter is then treated with dilute hydrochloric acid, which dissolves all but the sulphides of those metals which are precipitated in the usual course with hydrogen sulphide; cobalt and nickel are also left undissolved. For further details, Vortmann’s brochure is referred to.

In order to prepare ammonium sulphide without using a hydrogen sulphide apparatus, distillation of sodium sulphide with ammonium chloride solution is recommended.

L. de K.

Use of Certain Organic Acids and Acid-Anhydrides for the Standardisation of Alkali and Acid Solutions. Isaac K. Phelps and L. H. Weed (Zeitsch. anorg. Chem., 1908, 59, 114—119).—Experiments are recorded which show that succinic acid, succinic anhydride, malonic acid, benzoic acid, phthalic acid, and phthalic anhydride can be used, with phenolphthalein as indicator, for the titration of sodium and barium hydroxide solutions with the same degree of accuracy as a solution of hydrochloric acid standardised by precipitation with silver nitrate.

H. M. D.

Comparison between Succinic Acid, Arsenious Oxide, and Silver Chloride for the Standardisation of Solutions in Iodimetry, Alkalimetry, and Acidimetry. Isaac K. Phelps and L. H. Weed (Zeitsch. anorg. Chem., 1908, 59, 120—126. Compare preceding abstract).—Succinic acid can be accurately employed for the standardisation of sodium thiosulphate solutions. The authors’ method consists in standardising a pure sodium hydroxide solution by means of succinic acid. This solution is used to titrate a solution of a mineral acid, a known quantity of which is added to an excess of solution containing potassium iodide and iodate. The thiosulphate solution is then used to titrate the liberated iodine. Results quite as accurate as those yielded by the estimation of iodine with a standard arsenious oxide solution are obtainable. The liberation of iodine by mineral acids from an iodide-iodate solution is not complete in very dilute solution.

H. M. D.

Separation of Chlorine, Bromine, and Iodine by means of Hydrogen Peroxide in Acid Solution. Paul Jannasch (J. pr. Chem., 1908, [ii], 78, 28—34).—In continuation of the study of the separation of the halogens by means of hydrogen peroxide, a method has been worked out for the quantitative separation of chlorine, bromine, and iodine from each other. The haloid mixture is made acid with acetic acid and treated with hydrogen peroxide; the iodine is then distilled off in a current of carbon dioxide, collected in an
aqueous solution of ammonium hydroxide and hydrazine sulphate, and estimated as described previously (Abstr., 1906, ii, 194). The bromine and chlorine in the distillation residue are separated and estimated as before (Abstr., 1906, ii, 894), with the difference that the bromine is collected in a solution of sodium, instead of ammonium, hydroxide and hydrazine sulphate. The analyses quoted show that the method gives good results for chlorine and iodine, but that bromine is found slightly too low.

G. Y.

Detection and Estimation of Chlorites and Hypochlorites in Chlorates. Birger Carlson and Julius Gelhaar (Chem. Zeit., 1908, 32, 604—605, 633—634).—Qualitative Examination of Chlorates.—Five grams of the sample are dissolved in 100 c.c. of cold water and a drop of zinc iodide-starch solution is added. If no immediate blue colour is noticed, hypochlorites are absent. Two c.c. of N/10 sulphuric acid are now added, and if there is no immediate coloration, neither hypochlorites nor chlorites are present. These directions must be strictly adhered to.

Quantitative Estimation.—The following is an outline of the method employed: The hypochlorite is titrated in the usual manner with arsenious acid, the excess of which is then titrated with iodine. To another portion of the solution is now added the requisite amount of arsenic solution to destroy the hypochlorite, and, after diluting to 250 c.c. and heating to 95°, the solution is titrated as quickly as possible with indigo solution; if neutral or alkaline, the liquid should be acidified faintly with dilute sulphuric acid. The indigo solution is prepared by dissolving about 6 grams of sodium indigotinsulphonate in a litre of water, and should be checked with a solution of chlorite, checked in turn with standard iodine and thiosulphate. L. de K.

Estimation of Sulphur in Iron and Steel. Max Orthley (Zeitsch. angew. Chem., 1908, 21, 1359—1364, 1393—1399).—The following published processes may be recommended. They are all based on the evolution of the sulphur as hydrogen sulphide and absorption of the latter in cadmium acetate solution; the cadmium sulphide is converted by means of copper sulphate into copper sulphide, which is then burnt to oxide (1, 2, 3, 4), or the cadmium sulphide is estimated iodometrically (5, 6):

1. The sample is treated with hydrochloric acid, D 1.19. (2) The gases are passed through a red-hot tube. (3) The hydrochloric acid fumes are condensed in a little water, which is afterwards boiled to expel any hydrogen sulphide. (4) A mixture of zinc and cadmium acetate is used. (5) An ammonia solution of cadmium acetate is used. (6) An acetic acid solution is employed.

In the case of steel, the following methods may be used also: (7) The sample is dissolved in dilute hydrochloric acid (1 : 2), and the gases passed through a red-hot tube. (8) Acid, D 1.124, is used, and the gases ignited. (9) The same, but a mixture of dilute hydrochloric acid (1 : 2) and dilute sulphuric acid (1 : 4) is used instead. For reference, analyses 3, 4, 5, and 6 should be used.
Good results are obtained also by the following methods, where the sulphur is finally weighed as barium sulphate: (a) The sample is dissolved in strong hydrochloric acid, and the heated gases are passed through ammomiacal hydrogen peroxide. (b) The sample is oxidised with nitric acid, D 1·42, the nitric acid is expelled by excess of hydrochloric acid, and the ferric chloride removed by shaking with ether; or the iron is precipitated with ammonia, and, after adding barium chloride, the ferric hydroxide is re-dissolved by hydrochloric acid. (c) The iron is treated with copper-ammonium chloride, and the residual matter oxidised with nitro-hydrochloric acid and potassium chlorate.

L. DE K.

Decomposition of Certain Minerals and Industrial Products by means of Sodium Peroxide and Metallic Sulphides. JAMES H. WALTON, JUN., and HERMAN A. SCHOLZ (Amer. Chem. J., 1908, 39, 771—789).—A method is described for decomposing certain mineral substances, and is particularly applicable to sulphide ores and products containing a large proportion of silica, such as glazes and slags. The decomposition is effected by fusing the material in a nickel crucible with a mixture of sodium peroxide, zinc sulphide, and potassium persulphate. In the case of basic substances, such as franklinite and chrome iron ore, iron pyrites is added in order to increase the temperature.

The method yields accurate results, and is very rapid; the silica is brought into solution, and therefore does not tend to clog the filters, and the use of platinum crucibles is obviated.

E. G.

Colorimetric Estimation of Phosphorus in Steel. G. MISSON (Chem. Zeit., 1908, 32, 633).—The reagents required are (1): Pure nitric acid, D 1·2. (2) Potassium permanganate, 8 grams per litre. (3) Pure hydrogen peroxide, prepared by introducing gradually 40 grams of sodium peroxide into a cold mixture of 900 c.c. of water and 100 c.c. of nitric acid. (4) Ammonium vanadate, prepared by dissolving 2·345 grams of the salt in 500 c.c. of water, adding 20 c.c. of nitric acid, and diluting, when cold, to one litre. (5) A freshly-prepared 10% solution of ammonium molybdate.

One gram of the sample is dissolved in 20 c.c. of reagent (1), and boiled and mixed with 10 c.c. of reagent (2). After boiling a few seconds longer, 10 c.c. of reagent (3) are added to redissolve the manganese precipitate, then 10 c.c. of reagent (4), and the excess of peroxide is removed by boiling. When cold, the liquid is diluted to 60—65 c.c., 10 c.c. of reagent (5) are added, and the whole is diluted to 800 c.c. exactly. After two or three minutes, the coloration is compared with that of a standard sample treated similarly; the colour is stable for several days.

L. DE K.

Estimation of Phosphoric Acid in Foods. EMIL WÖRNER (Zeitsch. Nahr. Genussm., 1908, 15, 732—734).—According to the process described, the organic matter of the food is destroyed by heating with sulphuric and nitric acids, the phosphoric acid is then precipitated by the addition of ammonium molybdate solution, and the amount of phosphoric acid in the precipitate is estimated volumetrically.
From 1 to 5 grams of the dry sample are heated in a flask with 5 c.c. of concentrated sulphuric acid and 5 c.c. of nitric acid until the nitric acid has been expelled and fumes of sulphuric acid are evolved. If the remaining solution is dark in colour, a little more nitric acid is added and the heating continued. The solution is cooled, diluted with 20 c.c. of water, boiled for a short time, and filtered to remove silica and any trace of undecomposed fat. The filtrate, amounting to 100 c.c., is then treated with 30 c.c. of 50% ammonia, heated to a temperature of about 80°, and 25 c.c. of 10% ammonium molybdate solution are added. The mixture is shaken for a short time and, after the lapse of fifteen minutes, filtered, and the precipitate washed with water by decantation until free from acid. The filter is next placed in the flask containing the precipitate, 150 c.c. of water are added, a measured quantity of N/2 sodium hydroxide solution (about 5 c.c. more than is required to dissolve the precipitate) is introduced, and the contents of the flask are boiled until all the ammonia has been expelled. The excess of sodium hydroxide is then titrated back, using phenolphthalein as indicator. Each c.c. of N/2 sodium hydroxide solution is equivalent to 0.001268 gram of phosphoric anhydride or to 0.000556 gram of phosphorus.

W. P. S.

Estimation of Phosphates in Urine. Annibale Ferraro (Boll. chim. farm., 1908, 47, 399—400).—In the estimation of phosphates in urine by Neubauer’s method, the uranium solution must be run in in drops throughout, with brisk agitation, the solution to be tested being kept at the temperature of the boiling-water bath. The last reading should be taken after six to seven minutes of rapid stirring. When much calcium phosphate is present, it is better to run the solution to be tested from a burette into the uranium solution. Potassium ferrocyanide is to be preferred to cochineal as an indicator.

C. H. D.

The Dyer Method for the Determination of Plant Food in Soils. Frank T. Shutt and A. T. Charron (J. Amer. Chem. Soc., 1908, 30, [iv], 1020).—Experiments are recorded showing the effect of (1) the time of digestion and (2) the volume of the solvent in making analyses of soil by Dyer’s method (Trans., 1894, 65, 115). The authors used a rich black loam from the prairie at Tisdale, Sask., described as typical of large areas in the Canadian north-western wheat belt, and characteristically rich in nitrogen and organic matter. Four sets of determinations were made: samples weighing 100 grams of soil were extracted for (a) seven days, (b) five hours, with 1000 c.c. of 1 per cent. citric acid, and (c) seven days, (d) five hours, with 500 c.c. of 1 per cent. citric acid; the results were:

A reduction in the volume of the solvent has materially reduced the percentages of phosphoric acid, potash, and especially of lime
ABSTRACTS

P. 1908, the L. physiol. 7;>1 alcoholic (D which Presence potassium of hydrogen sulphurous solution using 1100 c.c. Detection Iodometric Kjeldahl flask, occasionally adding 0.5 c.c. of nitric acid until oxidation is complete. Various other practical details are discussed.

Detection of Arsenic in Urine. Ernst Salkowski (Zeitsch. physiol. Chem., 1908, 56, 95—114).—The paper is mainly concerned with methods for oxidising the urine prior to the application of Marsh’s test. The method recommended is to oxidise the evaporated alcoholic extract of the urine by treatment with 15 c.c. of nitric acid (D 1.48), and then to heat the mixture with 10 c.c. of sulphuric acid in a Kjeldahl flask, occasionally adding 0.5 c.c. of nitric acid until oxidation is complete. Various other practical details are discussed.

G. B.

Iodometric Estimation of Arsenic and Antimony in the Presence of Copper. F. H. Heath (Amer. J. Sci., 1908, [iv], 513—519; Zeitsch. anorg. Chem., 1908, 59, 87—93).—The solution, which must contain the arsenic or antimony in the higher state of oxidation, is mixed with 1—2 grams of citric acid and then with potassium iodide (3 grams to 50 c.c., 5 grams to 100 c.c.). The iodine liberated, which represents the copper, is then titrated with standard thiosulphate. The filtrate from the cuprous iodide is treated with 1 c.c. of bromine and boiled in order to expel the iodine, if necessary with further addition of bromine, which is then in turn boiled off completely. The whole is now diluted to 100 c.c., and, after adding 2 grams of potassium iodide, the solution is boiled down to half its bulk. When cold, any free iodine is decolorised with sulphurous acid, using starch as indicator. After diluting again to 100 c.c., iodine solution is added until the liquid is coloured, and then very dilute sulphurous acid to make the colour disappear. Excess of sodium hydrogen carbonate is now added, and the arsenic or antimony titrated with standard iodine in the usual way.

When both arsenic and antimony are present, the copper estimation is not quite so satisfactory.

L. de K.

P. H.

Volumetric Estimation of Carbon Dioxide and other Acids in Air. H. Henriët and M. Bouysse (Compt. rend., 1908, 146, 1100—1101).—The air is passed through standardised sodium or potassium hydroxide solution, and the latter is then diluted to a definite volume. One-half is next titrated with acetic acid, using phenolphthalein as indicator, and the decrease in titre of the solution multiplied by 2 is equivalent to the amount of carbon dioxide in the air; the neutral point is reached when the normal carbonate formed has been converted into hydrogen carbonate. The second half of the solution is then treated with barium chloride, and titrated with acetic acid without removing the barium...
carbonate. The quantity of alkali required to neutralise the total acidity of the air is thus obtained, and the amount of the acids other than carbon dioxide may be calculated. W. P. S.

The Autolysator, an Apparatus for the Automatic Estimation of Carbon Dioxide. CHARLES A. KEANE and HARRY BURROWS (J. Soc. Chem. Ind., 1908, 27, 608—610).—The apparatus is used for the automatic analysis of furnace gases. The absorption of the carbon dioxide is effected by means of soda-lime, and the pressure of the gas before and after the absorption is measured by differential manometers. The gas to be analysed is drawn by water suction of constant pressure through two similar capillary tubes, each of which is connected with a manometer. By interposing the absorbent substance between the two capillaries, the difference in pressure due to the absorption of the carbon dioxide is indicated on the manometer, provided that the flow of gas be so regulated that a constant volume flows through the apparatus. A full description, with diagrams, of the apparatus is given in the original paper. W. P. S.

Application of the Cobaltinitrite Method to the Estimation of Potassium in Soils. W. A. DRUSHEL (Zeitsch. anorg. Chem., 1908, 59, 97—101. Compare this vol., ii, 66).—The method already described is applied to the estimation of potassium in soils. A weighed quantity of soil is extracted on the water-bath with 20% hydrochloric acid. The acid is then removed by evaporation, and the bases separated by addition of sodium carbonate or ammonia and ammonium oxalate. After removal of the ammonium salts and the organic matter by heating to redness, the residue is dissolved in water, acidified with acetic acid, and evaporated with excess of sodium cobaltinitrite. The further procedure is exactly the same as that previously described (loc. cit.). H. M. D.

Estimation of Lead in Alloys. W. ELBORNE and C. M. WARREN (Chem. News, 1908, 98, 1).—One gram of the alloy in fine shavings is put into a flask with 50 c.c. of hydrochloric acid, and a slow current of chlorine is passed for twenty-four hours. When all is dissolved (sometimes heat must be applied towards the end), the solution is transferred to a small weighed porcelain dish, evaporated to dryness on a water-bath, and the residue cooled in a desiccator.

The mass is then treated repeatedly with absolute alcohol; this dissolves all the chlorides present except the lead chloride, which is then dried at 100° for three hours and weighed. For fear any lead chloride may be lost, the filtrate and washings are passed through a weighed filter, which is then also dried at 100°. L. DE K.

Rapid Valuation of Pastilles of Mercuric Chloride and Cubes of Sodium and Potassium Iodides. PAOLO FIORA (Boll. chin. Farm., 1908, 47, 401—402).—The mercuric chloride pastille (1 gram) is dissolved in water, and a solution of 11.62 grams of potassium iodide added. After filtering, a 1% solution of mercuric
chloride is added, the formation of a precipitate indicating a deficiency in the pastille. The quantity given allows a margin of 0.05 gram. For 1 gram cubes of potassium and sodium iodides, 0.776 and 0.859 gram of mercuric chloride are added respectively, a very dilute solution of potassium iodide being used for titrating back.

C. H. D.

Estimation of Cerium in the Presence of Other Rare Earths by the Action of Potassium Ferricyanide. Philip E. Browning and Howard E. Palmer (Amer. J. Sci., 1908, [iv], 26, 83—84; Zeitsch. anorg. Chem., 1908, 59, 71—73).—To a measured portion of the cerous sulphate (containing about 0.1 gram of cerium), which may contain also the sulphates of the other rare earths, are added 20 c.c. of 2% ferricyanide solution, and then a slight excess of aqueous potassium hydroxide. The precipitate is filtered off, and the filtrate and washings, amounting to about 200 c.c., are slightly acidified with dilute sulphuric acid, and the ferrocyanide formed by the reducing action of the cerous salt is then titrated as usual with standard permanganate; 2 mols. of ferrocyanide = 1 mol. of cerous oxide.

L. De K.

Estimation of Iron and Vanadium in the Presence of Each Other. Graham Edgar (Amer. J. Sci., 1908, [iv], 26, 79—82; Zeitsch. anorg. Chem., 1908, 59, 74—78).—The process is based on the fact that ferric iron is reduced to the ferrous state both by the action of sulphur dioxide and amalgamated zinc, but in the case of vanadic acid, the reducing action of sulphur dioxide goes as far as $V_2O_4$ only, but that of zinc to $V_2O_3$. The difference in permanganate used for re-oxidation after reduction with sulphur dioxide and the second reduction with zinc is a measure for the amount of vanadium present.

The solution is saturated with sulphur dioxide, a few c.c. of dilute sulphuric acid are added, and the liquid boiled in a current of carbon dioxide free from air. When all the sulphur dioxide has been removed, the flask is cooled rapidly, and the liquid titrated with standard permanganate until the colour changes from blue to yellowish-green; the liquid is then heated to 70—80°, and the titration continued. The liquid is now passed through a column of amalgamated zinc contained in a long Jones’ reductor, being preceded by 150 c.c. of hot dilute 2½% sulphuric acid. After washing the zinc with 100 c.c. of the acid and then with 200 c.c. of water, the contents of the receiving flask (into which some pure ferric sulphate had been introduced, and which has been kept cool) are mixed with syrupy phosphoric acid and titrated with permanganate until the reaction is nearly at an end; the temperature is then raised to 70—80°, and the titration continued.

L. De K.

Simultaneous Volumetric Estimation of Iron and Vanadium [in Ferro-Vanadium]. T. Warynski and B. Mdivani (Ann. Chim. anal., 1908, 13, 210—212).—Three to four grams of the alloy are treated several times with nitrohydrochloric acid and nitric acid and evaporated to dryness, and the residue is boiled with dilute nitric acid and filtered
off from any silica. The filtrate is then evaporated with addition of hydrogen peroxide, and then again several times with sulphuric acid to expel the nitric acid. The mass is then dissolved in very dilute sulphuric acid, and diluted to 500 c.c.; 100 c.c. are taken for the estimation of the vanadic acid only by Bunsen and Mohr's method (distillation with hydrochloric acid, collecting the distillate in potassium iodide, and determining the iodine liberated). Another 100 c.c. are then taken for the joint estimation of the ferric oxide and vanadic acid by the authors' stannous chloride method (compare this vol., ii, 636).

Estimation of Chromium as Silver Chromate. FRANK A. GOOCH and L. H. WEED (Amer. J. Sci., 1908, [iv], 26, 85—86; Zeitsch. anorg. Chem., 1908, 59, 87—93).—Chromium in the state of chromate or dichromate may be accurately estimated by adding to the solution an excess of silver nitrate, then a slight excess of ammonia, and finally acetic acid to slightly acid reaction. The silver chromate is collected on a Gooch filter, washed first with a dilute solution of silver nitrate to remove any soluble impurities, and then with small portions of water, 20—30 c.c. in all. The precipitate may be dried at 135°, or gently over a naked flame.

Estimation of Tungstic Acid and its Separation from other Substances by means of a Mixture of Chlorine and Sulphur Chloride. FRANÇOIS BOURION (Compt. rend., 1908, 146, 1102—1104).—It has been shown previously (Abstr., 1904, ii, 341) that tungsten trioxide when heated strongly in a mixture of chlorine and sulphur chloride yields volatile oxychlorides, and the method now proposed is based on this reaction; it is applicable to the estimation of tungsten trioxide in sodium tungstate, silicotungstic acid, &c. A portion of the sample is placed in a porcelain or silica boat, and is then heated in a glass tube through which a current of chlorine containing a little sulphur chloride is passed. The volatile substances are collected in a receiver containing water, and, when the operation is at an end, the contents of the receiver are evaporated with nitric acid, heated to remove sulphuric acid, the residue is taken up with ammonium nitrate solution, and the tungsten trioxide is collected on a filter and weighed. If any of the oxychloride condenses on the sides of the glass tube, the latter may be rinsed with ammonia and the solution added to the contents of the receiver. The silica may be recovered by extracting the contents of the boat with water and weighing the residue.

A New Method of Separation of Silica and Tungsten Trioxide. ÉDOUARD DEFAÇOZ (Compt. rend., 1908, 146, 1319—1320. Compare Abstr., 1907, ii, 475; Marignac, Ann. chim. Phys., 1864, [iv], 3, 9; Friedheim, Henderson, and Pinagel, Abstr., 1905, ii, 614; Bourion, preceding abstract).—This is based on the facts that silica is unattacked, but tungsten trioxide is reduced by hydrogen at 600—900° either to lower oxides or to the metal, and that the latter are converted by chlorine into the volatile hexachloride
or oxychlorides. The mixture of silica and tungsten trioxide contained in a boat is heated to redness in a current of hydrogen. When the reduction is complete, the boat is introduced into a glass tube bent so as to admit of the condensation of volatile products, and heated in a current of dry chlorine. If the reduction has been complete and all the air has been expelled, a mixture of tungsten hexachloride and oxytetrachloride is volatilised, otherwise the product consists of a mixture of the red and yellow oxychlorides.

The receiver is washed out with dilute ammonia, and the tungsten estimated in one of the known ways. The silica remains in the boat, and should be quite white; it should give no colour reaction when fused with potassium hydrogen sulphate.

The method is generally applicable to mixtures of two oxides, only one of which is reduced by hydrogen to a metal, forming with chlorine a volatile chloride.

E. H.

Tables for Converting Percentages of Alcohol by Volume into Percentages by Weight. A. Blondeau (Bull. Assoc. chin. Sucr. Dist., 1908, 25, 1032—1045).—The tables given show the weights of alcohol corresponding with volumes of alcohol as determined by Gay-Lussac's hydrometer in mixtures of alcohol and water containing from 1 to 100% of alcohol by volume at any temperature between 0° and 30°

W. P. S.

Estimation of Alcohol and Extract in Spirits by means of the Refractometer. Joseph Race (J. Soc. Chem. Ind., 1908, 27, 547—548).—A table is given showing the refractive indices of mixtures of alcohol and water containing from 1 to 100% of alcohol, the indices being given for each difference of 1%. Using this table, it is possible to estimate the quantity of alcohol and extract in a spirit. The refractive index of the spirit is taken at a temperature of 15.5°, and also that of the liquid obtained by evaporating 25 c.c. of the spirit almost to dryness and diluting the residue to the original volume. The difference between these results is due to the alcohol and other volatile constituents, and the difference between the refractive index of the extract and that of water is due to the extractive matters contained in the spirit.

W. P. S.

Messinger and Vortmann's Method of Estimating Phenols. Separation of Salicylic Acid. J. Bougault (Compt. rend., 1908, 146, 1403—1405).—The violet-red compound obtained by Messinger and Vortmann (Abstr., 1889, 1150) by the action of iodine and potassium hydroxide on phenol, and formed in these authors' method of estimating phenol (Abstr., 1890, 1473), is not a di-iododiiodosobenzene, C₆H₅I₂O, but a mixture of 2 : 4 : 6-tri-iodophenol with the red substance obtained by Lautemann (Annalen, 1861, 120, 309), and shown by Benzinger and Kämmerer (Abstr., 1878, 574) to be tetraiododiphenylenequinone.

Similarly, the substance obtained by Messinger and Vortmann from salicylic acid is a mixture of the same red substance with potassium 3 : 5-di-iodosalicylate. The extreme insolubility of Laute-
mann’s red substance furnishes a means of estimating and separating salicylic acid. For example, a mixture of 0·1 gram of salicylic acid and 0·2 gram of cinnamic acid is dissolved in 50 c.c. of water and 1 gram of sodium carbonate. Excess of iodine is added, the whole heated on the water-bath for twenty minutes, and finally boiled for ten minutes under reflux, iodine being added from time to time to ensure excess being present. The latter is removed by sodium sulphite, and the precipitate collected on a Gooch crucible. The weight multiplied by $138/344$ gives the weight of salicylic acid.

Lautemann’s red substance is produced by the action of iodine on a solution of $2 : 4 : 6$-tri-iodophenol in sodium carbonate.

J. C. C.

**Estimation of Orcinol in Orchella “Weed.”** Henry Edgar Watt (J. Soc. Chem. Ind., 1908, 27, 612).—The following method of estimating orcinol in Orchella weed (the name usually given to the lichen *Rocella tinctoria*) is given. Two grams of the powdered lichen are mixed in a mortar with 2 grams of sodium carbonate, and water is then added gradually until the mixture has a volume of 100 c.c. After being stirred occasionally for twenty minutes, the mixture is poured on a filter, and 50 c.c. of the filtrate are treated with an excess of standardised sodium hypochlorite solution. An excess of $N/10$ arsenious acid solution is immediately added, and the excess is titrated back with sodium hypochlorite solution, using as indicator starch-iodide solution acidified with acetic acid. The sodium hypochlorite solution must be standardised on pure orcinol. Four samples of orchella weed from the Seychelles were found to contain 11·5%, 1·6%, 8·8%, and 9·3% of orcinol respectively. In addition to the instantaneous reaction between orcinol and sodium hypochlorite on which the above method is based, a secondary and slower reaction appears to take place, and is not completed within twenty-four hours.

W. F. S.

**Estimation of Sugar.** Ivar Bang (Biochem. Zeitsch., 1908, 11, 538–540).—Further details of the author’s method are given, and Jessen-Hansen’s remarks on the theory of the reaction criticised.

W. D. II.

**Detection of Dextrose in Urine.** Andreas Otto (Pharm. Weekblad, 1908, 45, 809–813).—Kowarsky’s phenylhydrazine test may be recommended, but the precipitate should be recrystallised from alcohol in order to obtain the typical crystalline form of the glucosazone; a slight excess of acetic acid does not influence the result. A rapid crystallisation does not affect the nature or the size of the crystals. Two minutes boiling with the reagent is not necessary, although desirable; addition of sodium chloride is not always necessary. The reaction with alkaline bismuth solution (Nylander’s test) is accelerated and rendered more delicate by adding a few drops of platinic chloride, but attempts to make this a quantitative process by measuring the volume of the precipitate utterly failed, although there is no doubt as to the complete elimination of the dextrose. The addition of
platinic chloride is particularly of service if the phosphates have not been removed previously.

The ordinary Fehling test for sugar is not influenced by platinic chloride.

L. de K.

Detection of Sucrose. M. Emmanuel Pozzi-Escot (Bull. Assoc. chim. Sucr. Dist., 1908, 25, 1078).—A portion of the solution under examination is placed in a test-tube, and about 10 c.c. of concentrated sulphuric acid are then introduced, the test-tube being inclined so that the two liquids do not mix. If sucrose is present, a coloured ring appears at the junction of the liquids; the ring is red below and yellow above. The test will detect the presence of 0·00005 gram of sucrose. The reaction is also given by other carbohydrates, but it is most sensitive in the case of sucrose.

W. P. S.

Detection of Glycronic Acid by B. Tollens' Method in Human Urine. Karl Tollens (Zeitsch. physiol. Chem., 1908, 56, 115—116. Compare B. Tollens, this vol., ii, 639).—To 5 c.c. of urine, 0·5 c.c. of a 1% alcoholic solution of naphthoresorcinol and 5 c.c. of hydrochloric acid (D 1·19) are added; the solution is boiled for one minute over a small flame, left for four minutes, cooled, and extracted with ether. When glycuronic acid is present, the ether is coloured intensely blue, and when examined spectroscopically, shows a band near the sodium line.

G. B.

Estimation of Tartaric Acid in Argol and Wine Lees. M. Emmanuel Pozzi-Escot (Compt. rend., 1908, 146, 1031—1032; Ann. chim. anal., 1908, 13, 266—269; Bull. Soc. chim. Belg., 1908, 22, 218—221; Bull. Assoc. chim. Sucr. Dist., 1908, 25, 964—967).—The method proposed depends on the insolubility of barium tartrate in alcohol, and on the solubility of barium bromide in this medium. A weighed quantity of about 1 gram of the sample is treated with an excess of potassium carbonate solution, and the mixture is boiled and diluted to a volume of 100 c.c. Twenty-five c.c. of this solution are acidified with hydrochloric acid, boiled to remove carbon dioxide, and then rendered alkaline with ammonia. Forty c.c. of N/10 alcoholic solution of barium bromide and about 75 c.c. of 95% alcohol are added, the mixture is stirred, and the precipitate, consisting of barium tartrate, is collected on a filter and washed with alcohol. The precipitate may then be converted into barium sulphate and weighed as such, the tartrate being calculated from the weight of sulphate found, or the excess of barium bromide may be estimated in the filtrate. For this purpose, the filtrate is diluted with water, ammonium oxalate is added, the barium oxalate is collected on a filter, washed with dilute ammonia, then decomposed with hot dilute sulphuric acid, and the oxalic acid in the solution titrated with potassium permanganate solution. The difference between the quantity of barium bromide added and that found as oxalate in the filtrate is equivalent to the tartaric acid in the sample. W. P. S.
Viscosity and Lubrication. Charles F. Mabery and J. Howard Mathews (J. Amer. Chem. Soc., 1908, 30, 992—1001).—The viscosity of lubricating oils is usually regarded as a standard of quality, but probably does not afford a trustworthy indication of the comparative durability of oils differing widely in composition. If the viscosity constant is supplemented by chemical data and frictional durability tests, it may no doubt be depended on as giving accurate information for commercial purposes. A large number of hydrocarbons obtained by the fractional distillation of petroleum have been examined, and a series of frictional tests have been carried out with them in comparison with castor, sperm, and rape oils.

The lubricating value depends on the temperature reached during the frictional test, the degree of friction, and the time for which the oil continues to lubricate. The durability of the individual hydrocarbons increases with decrease in hydrogen, and in a similar ratio to the increase in specific viscosity. A hydrocarbon of the series C\(_n\)H\(_{2n-4}\) was found to be more efficient in reducing friction than castor, sperm, or rape oil. It was equal to sperm oil in temperature and coefficient of friction, and superior to castor and rape oils in durability.

With regard to the comparative value of the various series of hydrocarbons in petroleum from which lubricating oils are prepared, those of the C\(_n\)H\(_{2n+2}\) series have a low lubricating value. Lubricating oils from Pennsylvania petroleum consist chiefly of the C\(_n\)H\(_{2n}\) and C\(_n\)H\(_{2n-2}\) series, whilst those from the heavier oils are composed largely of hydrocarbons of the C\(_n\)H\(_{2n-2}\) and C\(_n\)H\(_{2n-4}\) series.

Comparative examination of distillates from South American and Pennsylvania petroleums has shown that neither sp. gr. nor b. p. can be depended on as indicating the lubricating value unless the source of the oil is known.

Nothing is at present known as to the constitution of the series of hydrocarbons in lubricating oils.

E. G.

Analysis of Hyposulphites and their Compounds with Formaldehyde. W. F. Greaves (J. Soc. Dyers, 1908, 24, 195—196).—For the estimation of formaldehyde in the formaldehyde compound of sodium hyposulphite, the method described by Cross, in which the compound is heated with chromic acid, is recommended as being trustworthy. A Lunge’s nitrometer is employed for measuring the carbon dioxide produced. The inner tube of a Lunge bottle is filled with 5 c.c. of cold saturated chromic acid solution, and 10 c.c. of a 10% solution of the compound under examination are placed in the part of the bottle surrounding the tube. The bottle is then connected with the nitrometer, the contents of the bottle are mixed and gently heated until the mixture just boils, the bottle is next cooled by placing it in cold water, and, at the end of one hour, the volume of the carbon dioxide is read off, the usual corrections for temperature, pressure, &c., being made. The method described by Knecht and Hibbert (Abstr., 1907, ii, 907) for the estimation of sodium hyposulphite can be applied to the analysis of hyposulphite compounds which are not decomposed by water.

W. P. S.
Folin's Method for Separating Acetone and Acetoacetic Acid in Urine. T. Stuart Hart (J. Biol. Chem., 1908, 4, 473—476. Compare Abstr., 1907, ii, 588).—Folin's method was found to be a valuable one. In cases where acetone is excreted, the amount is far more constant than that of acetoacetic acid. If the total amount of the two substances increases, the increase is largely due to the acetoacetic acid.

W. D. H.

Separation of Ammonia and Amines by means of Boiling Absolute Alcohol. Jean Bertheaume (Compt. rend., 1908, 146, 1215—1217; J. Pharm. Chim., 1908, 28, 8—13. Compare Jarry, Abstr., 1899, ii, 738; Brochet and Cambier, Bull. Soc. chim., [iii], 13, 533).—In order to determine the trustworthiness of the method of separating amine hydrochlorides by means of boiling absolute alcohol, the author has determined the solubilities of methylamine hydrochloride, ammonium chloride, and a mixture of the two in this solvent. The amine hydrochloride was prepared from bromoacetamide, and purified from ammonia by yellow mercuric oxide.

The quantities of the salts dissolved separately were determined by evaporation of the solutions and desiccation at 110°; in the case of the mixture of the two salts, François' method of analysis (Abstr., 1907, ii, 503) was employed. The values obtained were:

| 100 grams absolute alcohol at 82° dissolve | 23.01 grams NH₃MeCl. |
| 100 " " " " 78.5 " 1.538 " NH₄Cl. |
| 100 " " " " 0 " 0.778 " NH₄Cl. |
| 100 " " " " 82 " { 25.0 " NH₃MeCl and NH₄Cl. |
| 100 " " " " 0 " { 6.0 " NH₃MeCl and NH₄Cl. |

From these results, it is obvious that the solubility of each salt in boiling alcohol is increased in the presence of the other, that when a mixture of methylamine and ammonium hydrochlorides is extracted with boiling alcohol the two salts are dissolved in the proportion 11:1, and that on cooling to 0° the solution deposits 1.616 grams of ammonium chloride per 19 grams of methylamine hydrochloride, that is, a mixture containing 85% of the latter salt.

Employing François' method of analysis, the author finds (1) that if a saturated aqueous solution of pure methylamine hydrochloride is saturated with ammonium chloride at 15°, the product deposited on evaporation contains 9.2% of the latter salt; (2) that the crystals first deposited by a boiling alcoholic solution of Brochet and Cambier's crude methylamine hydrochloride contain 10.8% of ammonium chloride, and (3) that a saturated solution of ammonium and methylamine hydrochlorides in boiling absolute alcohol deposits, on cooling, crystals containing 8.5% of ammonium chloride.

These results are contrary to the general opinion that ammonium chloride is insoluble in saturated aqueous or alcoholic solutions of methylamine hydrochloride.
The conclusion is drawn that the method of separation is of very little use.

E. H.

A Rapid and Delicate Method of Detecting Bile-pigments in Urine. **William Macadie (Pharm. J., 1908, [iv], 28, 686).**—A modification of Gmelin’s test. The urate precipitate, produced by adding a saturated solution of calcium chloride to the faintly acid urine, contains the bile-pigments; it is dissolved in a mixture of 1 part of hydrochloric acid (D 1.16) and 3 parts of alcohol, and while still in the centrifuge-tube, 5—6 drops of nitric acid, D 1.42, are added.

G. B.

Proposed Method for the Routine Valuation of Diastase Preparations. **William A. Johnson (J. Amer. Chem. Soc., 1908, 30, 798—803).**—Commercial potato-starch is washed, pressed dry, and dried gradually finally at 80°. The remaining water, generally about 10%, is then estimated. Other starches should not be employed. A quantity corresponding with 20 grams of anhydrous starch is then stirred with 100 c.c. of water, and poured into a flask containing 800 c.c. of boiling water; the boiling is continued for ten minutes, and hot water is added up to 1000 grams.

Fifty grams of the starch solution are weighed out into a series of flasks kept at 40°. To each are added increasing portions of the diastase solution (for instance, liquid malt ten times diluted). After ten minutes each bottle is tested for free starch with dilute iodide solution. This then gives an idea of the strength of the diastase product, as it shows how much is wanted to convert the starch into dextrin and sugar in a given time. The operation is then repeated, using double the quantities of starch solution and diastase solution. As a check, the sugar formed may be estimated.

L. de K.

Colorimetric Method Applicable to both Peptic and Tryptic Enzymes. **Herbert E. Roaf (Bio-Chem. J., 1908, 3, 188—192).**—Grützner’s method of estimating the rate of proteolysis by the amount of carmin liberated from fibrin stained with that pigment has the disadvantage that it is only applicable to enzymes which, like pepsin, act in an acid medium; if used for trypsin, the dye is liberated by the alkali employed. Congo-red may be substituted for carmin, and fibrin stained with it may be used for both peptic and tryptic ferments.

W. D. H.

Ferments and Anti-ferments. VII. Detection of Trypsin. **Martin Jacoby (Biochem. Zeitsch., 1908, 10, 229—231. Compare Abstr., this vol., i, 236).**—A solution of ricin or a suspension of edestin remains cloudy in the absence of trypsin, and becomes clear when trypsin is present in an alkaline medium.

W. D. H.

Süchtling’s Method for Estimating Acidity of Soils. **A. J. van Schermbeek (J. pr. Chem., 1908, [ii], 77, 489—497).**—In Tacke’s method for estimating soil acidity (Abstr., 1908, ii, 103), it is assumed that no acid is produced during the four hours required for
the determination. It is pointed out that, whilst under natural conditions the production of acids in the soil is checked when the acidity reaches a certain limit, the soil water is greatly diluted in the process referred to, and conditions are thus produced which are favourable to increased decomposition of the organic matter; the error is further increased by addition of calcium carbonate. Süchtling's modification (this vol., ii, 231) has the advantage that the time required is reduced to about half; nevertheless, it yields results which may be far too high. A peaty sand, for example, showed an amount of acid corresponding with 1.44% HCl in the soil water, which is fifty to sixty times the amount in which it is possible for roots to live.

Correct results can only be obtained under conditions of sterilisation.

N. H. J. M.

Separation of Clay in the Estimation of Humus. C. A. Mooers and H. H. Hampton (J. Amer. Chem. Soc., 1908, 30, 805—807).—Determinations of the humus by evaporating the ammoniacal extract to dryness on a water-bath, so as to coagulate the clay, redissolving in 4% ammonia, and filtering, shows that this method gives more uniform results than direct filtration through a Pasteur-Chamberland filter, which gives low results, chiefly owing to loss of humus in the filter. Peter and Averitt's method (Kentucky Stat. Bul., No. 126, 63—126), in which a factor is employed for correcting for loss in the clayey residue, was also found to be unsatisfactory; the results were not concordant, and the factor (10%) too low for the soils examined.

A number of determinations of humus in soils limed three years previously, and in the unlimed soils, showed that the small differences due to lime can be detected by the evaporation method described above.

N. H. J. M.

The Action of Heat on the Lecithin-Phosphoric Acid Contained in Pastry. W. Ludwig (Zeitsch. Nahr. Genussm., 1908, 15, 665—680).—It is shown that a considerable decrease in the amount of lecithin-phosphoric acid present in pastry takes place when the latter is heated for some time at a temperature of 102°. The loss is particularly marked in samples containing but little egg-material, and may amount to as much as 40%, calculated on the quantity present before the heating. The decrease is not due to loss of volatile-phosphorus compounds, but to a portion of the lecithin being rendered insoluble in the solvents employed in the estimation of the lecithin-phosphoric acid. The total amount of phosphoric acid is the same after as before the heating. A small decrease in the amount of lecithin-phosphoric acid was also noticed when the pastry was kept for a few months. The author finds that practically the whole of the lecithin-phosphoric acid may be obtained in solution by boiling the pastry three times with absolute alcohol, the boiling being continued for twenty minutes each time.

W. P. S.
General and Physical Chemistry.

Magnetic and Electric Double Refraction of Nitrobenzene. Variation with Wave-length. A. Cotton and Henri Mouton (Compt. rend., 1908, 147, 193—195. Compare Abstr., 1907, ii, 727; this vol., ii, 2).—The differences between the ordinary and extraordinary indices of refraction of nitrobenzene in the magnetic field increase regularly when the wave-length of the light diminishes. Measurements have been made with the yellow, green, and indigo mercury lines, and with the C and F lines of hydrogen. Kerr’s phenomenon has been studied in the case of pure nitrobenzene, using small differences of potential, and it is found that the dispersion is the same in the case of electric as in the case of magnetic double refraction; the temperature-coefficient is also approximately the same for each. The two phenomena therefore appear to have a common origin, and this may be sought in molecular orientation.

W. O. W.

Spectrum of the Discharge from a Glowing Lime Cathode in Mercury Vapour. F. Horton (Proc. Camb. Phil. Soc., 1908, 14, 501—507).—The spectrum of the discharge between an electrically heated Wehnelt cathode and an aluminium anode exhibits five new lines, which are shown to be due to mercury. The wave-lengths of the lines are 6912, 6715, 6232, 6121, and 6070. The fact that these have not been described previously is supposed to be due to their absence from the ordinary arc or spark spectrum.

H. M. D.

Spectra of the Calcium Flame. Gustave A. Hemsalech and Charles de Watteville (Compt. rend., 1908, 147, 188—190).—A spectrophotographic study of the calcium flame obtained by the apparatus previously described (this vol., ii, 336). The spectra are considerably richer in lines than the flame spectra hitherto obtained. A table is given showing the wave-lengths of the lines and also their relative intensities when the spark is used in conjunction with air-gas, air-hydrogen, oxygen-coal gas, and oxyhydrogen flames, and also when the de Watteville pulverisation method with an air-gas flame is employed.

W. O. W.

Absorption Spectra of some Compounds obtained from Pyridine and Collidine. John E. Purvis (Proc. Camb. Phil. Soc., 1908, 14, 435—440. Compare Baker and Baly, Trans., 1907, 91, 1122).—The absorption band of 3:5-dichloropyridine is found to be displaced towards the red end of the spectrum when compared with that of pyridine. The amount of the displacement and the persistence of the band are, however, smaller than has been found in the case of 3:4:5-trichloropyridine. These effects are in agreement with previous observations relating to the influence of the introduction of chlorine into the pyridine nucleus.

Vol. xciv. ii. 51
The absorption band of collidine hydrochloride is also displaced towards the red end relatively to that of the free base, and the persistence of the band is increased by union with hydrochloric acid.

Observations have also been made with the heptachlorolutidine obtained by Sell and Foster from the enenachlorocollidine previously examined. Compared with that of the latter substance, the absorption band of heptachlorolutidine is displaced towards the red, and its persistence is considerably greater.

H. M. D.

Change of the Colour of Fluorescence with the Solvent. Heinrich Ley and K. von Engelhardt (Ber., 1908, 41, 2509—2516).—It has been observed repeatedly that the colour of fluorescence depends on the nature of the solvent in which the fluorescent substance is dissolved. Kehrmann and Messinger (Abstr., 1892, 889) and Kauffmann and Beisswenger's investigations (Abstr., 1905, ii, 131) point to a relation between the colour of fluorescence and the dielectric constant of the solvent, whilst Stark (Abstr., 1907, ii, 147) draws attention to the relation of fluorescence to selective absorption. The present authors have now studied the changes in the absorption spectra of substances with varying fluorescence when dissolved in various solvents, the absorption curves being carried into the ultra-violet. As objects of study were chosen 5-amino-2-phenyl-2 : 1 : 3-benzotriazole,

\[
\text{NH}_2\text{C}_6\text{H}_4\stackrel{N}{\longrightarrow}\text{NPh}
\]

(Kehrmann and Messinger, loc. cit.), and dimethylphthaleinurhodine (Kauffmann and Beisswenger, loc. cit.) in methyl-alcoholic, ethyl-alcoholic, ethereal, chloroform, ethyl acetate, and carbon disulphide solutions. The results are tabulated and expressed in curves.

It is found that with the benzotriazole, the fluorescence changes from bluish-green through blue to bluish-violet, and the absorption is shifted towards the ultra-violet when the base is dissolved in alcohol, ether, and chloroform in the order named. That the solution in carbon disulphide is not fluorescent is to be ascribed to the formation of an additive compound, in agreement with which it is found that the solution in carbon disulphide is stable towards light, whereas the solutions in other solvents, especially in chloroform, are rapidly decomposed on exposure to light. The fluorescence is weakened by addition of acids, but disappears only in presence of an excess of hydrochloric acid; this change also is expressed in the absorption curve. It is probable that the hydrochloride fluoresces in the ultra-violet.

With the eurhodine base, also, the colour of the fluorescence changes with the shifting of the absorption towards the ultra-violet, but in the order of solvents: alcohol, chloroform, ethyl acetate, ether, from reddish-yellow through yellowish-green to yellow.

G. Y.

Fluorescence and Photo-electric Sensitiveness of Organic Substances. Johannes Stark and W. Steubing (Physikal. Zeitsch., 1908, 9, 481—495. Compare Abstr., 1907, ii, 147, 417; this vol., ii, 138).—The authors have made experiments on a large number of
substances to ascertain the relationship between fluorescence, on the one hand, and the nature of the banded absorption spectrum and the photo-electric effect, on the other.

Benzene and derivatives of it containing no other chromophoric group exhibit fluorescence bands which, like the corresponding absorption bands, decrease in intensity with increasing wave-length. The fluorescence spectrum of benzene is situated in the region of smallest wave-lengths, substitution of one or more hydrogen atoms leading to a displacement of the spectrum towards greater wave-lengths. The same phenomenon is met with in the case of condensed or coupled ring compounds. The displacement produced by successive substitution shows a gradual decrease. Of the various substituting groups investigated, the methyl group produces the least displacement and the amino-group the greatest. The fluorescence spectrum of benzene, naphthalene, anthracene, phenanthrene, and certain other aromatic hydrocarbons consists of several distinct bands, but if hydrogen in the ring is substituted by another element or group, or if two benzene rings are coupled by other atoms than carbon and hydrogen, a continuous spectrum is obtained. Substances containing a chromophoric group, but not a benzene ring, do not exhibit fluorescence.

As a result of the examination of the photo-electric properties, the conclusion is drawn that substances which fluoresce are also photo-electrically active. The greater the photo-electric effect the more intense is the fluorescence. Quinine sulphate is an exception, and it is suggested that this is due to a difference in the constitution of the solid and the dissolved substance.

The fluorescence of benzene derivatives containing another chromophoric group has been examined. The behaviour of these can be anticipated from that of the two simpler classes of substances.

An explanation of the phenomena of fluorescence and of photo-electric activity is given in terms of the electronic theory discussed in the authors' previous papers.

H. M. D.

A Case of Anomalous Rotatory Dispersion. Application of Measurements of Rotatory Dispersion to the Study of the Composition of Oil of Turpentine. Eugène Darmois (Compt. rend., 1908, 147, 195—197).—French levorotatory turpentine has practically constant properties, and probably contains l-pinene. Other oils are usually dextrorotatory, and probably contain d-pinene. The rotatory dispersion of certain levo- and dextro-oils has been studied, and it is found that the dispersion is normal, but varies with the oil examined. Certain mixtures of dextro- and levo-oils, however, exhibit anomalous dispersion, the results not being in accordance with those calculated from Biot's law of mixtures. These mixtures can, moreover, be produced by distillation of any dextro-oil, by stopping the operation at the right point. The conclusion is drawn that the two dextro- and levo-oils are not chemically homogeneous. Crystallisable l-pinene has been isolated from the levo-oil. The dextro-oil probably contains d-pinene together with an unknown substance having less dispersive power than l-pinene.

W. O. W.
Triboluminescence of Racemic Compounds. Désiré Gernez (Compt. rend., 1908, 147, 11—15. Compare Tschugaeff, Abstr., 1905, ii, 132).—A number of d- and l-tartrates and the corresponding racemates have been examined with the object of testing Tschugaeff’s theory, that when the two active forms are triboluminescent the racemic compound is not. In confirmation of the theory, the author finds that l-tartaric acid, like the dextro-modification, is triboluminescent and racemic acid is not. Dextro- and lœvo-potassium tartrates and potassium racemate, and d- and l-ammonium tartrates and ammonium racemate, obey the rule, as also does the double racemate of sodium and potassium, the constituents of which are both triboluminescent. Contrary to Tschugaeff’s statement, acid potassium racemate is triboluminescent as well as the acid potassium tartrates.

The following substances are all triboluminescent and contrary to Tschugaeff’s theory: the normal tartrates and racemates of rubidium, sodium, and thallium; the acid tartrates and racemates of ammonium, potassium, rubidium, sodium, and thallium, and the double racemates of ammonium-lithium, antimonyl-potassium, cesium-lithium, lithium-potassium, lithium-rubidium, lithium-sodium, lithium-thallium, rubidium-sodium, sodium-thallium. Lithium racemate is triboluminescent, but the lithium tartrates could only be obtained in a non-crystalline condition, and appeared to give no light when crushed.

The d- and l-tartrates and the racemates of quinine, strychnine, and brucine, and the acid d- and l-tartrates and acid racemates of cinchonine, strychnine, and brucine, are all crystalline substances exhibiting triboluminescence.

There are only six authentic cases in favour of Tschugaeff’s rule as compared with a large number in opposition to it. No general relation can be detected between molecular symmetry and triboluminescence.

R. J. C.

Thermodynamic Treatment of Photochemical Processes. Fritz Weigert (Zeitsch. physikal. Chem., 1908, 63, 458—466).—Various formulæ are deduced by the author, and their bearing on the experimental results obtained by Luther and Weigert (Abstr., 1905, ii, 785) are discussed. He reaches the result that in the system anthracene–dianthracene the energy which is chemically utilised in unit time is in all cases practically proportional to the light absorbed by the anthracene. If this is accepted, then it is possible on a thermodynamic basis alone to interpret all the experimental results observed by Luther and Weigert. The electrochemical theory recently propounded by Byk (this vol., ii, 339) appears to be unnecessary.

J. C. P.

Emission of Electricity from the Induced Activity of Radium. William Duane (Amer. J. Sci., 1901, [iv], 26, 1—13).—The rate of decay of the induced activity of radium has been investigated by measurements of the quantity of electricity carried by the a- and β-rays instead of the ions produced by these. The induced
activity was deposited on the surface of a small metallic cylinder, which, during the electrical measurements, was supported co-axially inside a tube of the same metal in such a way that the distance between the outer surface of the cylinder and the inner surface of the tube only amounted to 0·44 mm. The current flow between the cylinder and the tube was measured by means of a quadrant electrometer.

The decay curves obtained in this way do not coincide with the curves corresponding with the diminution of the ionisation, and this is attributed to the emission of negative rays by radium-\( B \). From the variation of the rate of discharge with the time, the conclusion is drawn that the same quantity of electricity is discharged when radium-\( B \) changes into radium-\( C \) as when radium-\( C \) changes into radium-\( D \).

In a magnetic field parallel to the active surface, or an electrical field normal to the surface, the rate of discharge is altered; the magnitude of the observed effects is what would be expected if the charge were carried by electrons moving with velocities, normal to the active surface, of, or less than, \( 4 \times 10^8 \) cms. per second.

The number of ions produced by the \( \alpha \)-rays in air is less than 9000 times, and probably less than 3600 times the number of \( \beta \)-particles emitted by the active deposit in the same time. Assuming that each \( \alpha \)-particle from radium-\( C \) produces 180,000 ions, it follows that at least 20, and probably more than 50, electrons are emitted from an active (brass) surface for every \( \alpha \)-particle which is expelled from radium-\( C \).

The experiments also show that the ionisation caused by radium-\( B \) and radium-\( C \) in the air in the immediate neighbourhood of the active surface is approximately the same.  

H. M. D.

Coefficient of Absorption of Radioactive Emanations in Different Liquids. José Muñoz del Castillo (Anal. Fis. Quim., 1908, 6, 319—320).—A claim for priority (compare Kofler, this vol., ii, 80).

W. A. D.

Photographic Impressions Produced by Radium Emanation. José Muñoz del Castillo and Faustino Díaz de Rada (Anal. Fis. Quim., 1908, 6, 322—323).—Radioactive solutions having an activity of 2,100,000 volts per hour per litre produce very good radiographs with an exposure of thirty hours; solutions with an activity of 2100 volts per hour per litre in the same circumstances do not affect the plate.

W. A. D.

Radioactivity of Swedish Spring Waters. Hjalmar Sjögren and Naima Sahlbom (Arkiv. Kem. Min. Geol., 1908, 3, i, No. 2, 1—23).—The authors have examined about sixty spring waters from central and southern Sweden, and find in all cases evidence of the presence of a radioactive emanation. The samples of sea-water examined were found to be inactive. The degree of activity of a spring water depends on the chemical character and quantity of the water and on the depth of the spring. In some waters the emanation
is found to be more abundant in winter than in summer. A close connexion exists between the radioactivity and geological character of a well, water from the granite showing the highest and that from sedimentary rocks the lowest activity. In all cases, the radioactivity observed was found to correspond with that of radium. The ochre deposited by some of the springs exhibits slight radioactivity, but the mud deposits are quite inactive.

T. H. P.

Radioactivity of the Waters of Lerez. José Muñoz del Castillo (Anal. Fis. Quim., 1908, 6, 237—242).—An investigation of the rate of decay of the radioactivity of the highly active waters of Lerez (compare Abstr., 1907, ii, 218). The initial activity probably exceeds 10,000 volts per hour per litre, and diminishes according to an exponential equation similar to that characteristic of radium; after about fifty days, however, a nearly constant residual radioactivity of about 20 volts is reached. It is probable that the radium emanation is responsible for the greater part of the radioactivity of these waters, but some other active substance is also present.

W. A. D.

Radioactivity of Waters of Agaete (Canary Islands). Faustino Díaz de Rada (Anal. Fis. Quim., 1908, 6, 242—243).—The chalybeate water of the thermal springs of Agaete has a temperature of 25° and is decidedly radioactive, one sample having an activity of 8.9 volts per hour per litre.

W. A. D.

Radioactivity of Water from Cucho. José Muñoz del Castillo (Anal. Fis. Quim., 1908, 6, 350).—The water of the San Roque spring, in the valley east of Cucho, province of Burgos, contains hydrogen sulphide, and has a temperature of 15° and an initial activity of about 74 volts per hour per litre.

W. A. D.

Radioactivity of Mud from the Baths of Fitero Viejo. Faustino Díaz de Rada (Anal. Fis. Quim., 1908, 6, 344—350).—From the character of the radioactivity of the mud, it is concluded that radium is present partly in a form soluble in hydrochloric acid and partly in an insoluble form. Thorium is entirely absent, but actinium may be present.

W. A. D.

Radioactivity of Potassium and other Alkali Metals. J. C. McLennan and W. T. Kennedy (Physikal. Zeitsch., 1908, 9, 510—512.* Compare Abstr., 1907, ii, 217, 597).—The radioactivity of a large number of potassium salts and of certain salts of sodium, ammonium, lithium, rubidium, and calcium has been examined by measuring the saturation current produced by the various salts when distributed in thin uniform layers on the base of an ionisation chamber. All the potassium salts and metallic potassium were found to be radioactive, but when the activities are divided by the percentages of potassium in the various compounds, numbers are obtained which vary in the ratio of one to thirty-three. The author considers that this precludes the possibility that the radioactivity is a normal property of the potassium atom. With the exception of one

* and Phil. Mag., 1908, [vi], 16, 377—395.
sample of rock salt out of three examined, all the sodium salts and metallic sodium were found to be inactive. Ammonium chloride was found to be slightly active, rubidium alum and caesium chloride still less so, and the other salts showed no trace of activity. The activity of the salts other than those of the alkali metals is supposed to be due to traces of radioactive impurities.

The activity of the potassium salts is unchanged on heating, and attempts to separate active impurities by electrolysis, recrystallisation, solution in ethyl ether, and by precipitation with ammonium carbonate gave no positive result.

H. M. D.

Nature of the γ-rays. **Joseph J. Thomson** (Proc. Camb. Phil. Soc., 1908, 14, 540).—Of the two views which have been advanced as to the nature of γ-rays: (1) that they are pulses of electromagnetic disturbance propagated through the ether; (2) that they are electrical doublets travelling with great velocity and possessing energy and momentum, it is pointed out that these approximate closely if it is supposed that the electromagnetic disturbance is distributed, not uniformly, but in patches over the wave-front. According to the pulse theory, the velocity of propagation of the rays should be equal to that of light, which is the case according to available experimental data. Barkla’s measurements of the polarisation of the secondary rays produced by the γ-rays are also in accord with the pulse theory. By means of these two factors, it is possible to differentiate between the two theories.

H. M. D.

**Velocity of Secondary Cathode Rays from Gases. Joseph J. Thomson** (Proc. Camb. Phil. Soc., 1908, 14, 541—545).—The blue pencil of cathode rays emanating from a Wehnelt cathode, on which the lime is confined to a small area, is surrounded by a blue haze. This is due to secondary rays produced by impact of the primary cathode rays against the gas molecules. If a piece of metal is inserted in the region occupied by the haze and the metal is negatively charged to a moderate potential, the negative particles of the haze are repelled and the metal is surrounded by a well-defined dark space. Experiments are described the object of which was to determine the difference of potential required to stop the negative particles. It is found that this potential difference is independent of the potential of the primary discharge, indicating that the energy of the secondary rays is independent of that of the primary rays. This result is in agreement with the view that the energy in the secondary rays is determined by the atoms emitting them. The energy of the secondary rays does not seem to vary much with the nature of the atoms emitting them, for air, hydrogen, and carbon dioxide give the same value, and this is very nearly equal to the value found by Füchtbauer for the secondary rays from metals.

From the potential difference required to stop the secondary rays, the velocity of these is calculated to be $3.7 \times 10^5$ ems. per second.

H. M. D.

**Positive Electrons. Jean Becquerel** (Compt. rend., 1908, 147, 121—124. Compare Abstr., 1907, ii, 421).—In order to justify the
suggestion that several experiments are best explained by assuming the existence of free positive electrons, the author critically examines his results to see whether they are explainable on any other hypothesis.

In the modified Crookes tube previously described, the beam issuing through the hole in the principal cathode appears to be separated by a magnetic field into (1) strongly deviated cathode rays (negative electrons); (2) canal rays (positive ions), which, being presumably attracted by the cathode corpuscles, are slightly deviated in the same direction; (3) rays which are strongly deviated in the opposite direction. The last are supposed to consist of positive electrons.

The positive charges direct themselves towards a second cathode, which is ring-shaped, and having passed through, produce a phosphorescence on a disk of willemite, although they are no longer deviable by a magnetic field. This phosphorescence is not due to the canal rays, which have insufficient penetrating power to reach the willemite. If the willemite disk is brought near to the second cathode, a phosphorescent patch due to canal rays can be seen distinct from that due to positive electrons. The former patch is practically unaffected on bringing a magnet near the second cathode, whereas the latter is notably displaced. The phosphorescent spot due to positive electrons is in respect of position, intensity, and shape independent of the distance of the willemite from the second cathode. The spot due to canal rays, on the other hand, is scarcely perceptible unless the willemite is quite near the second cathode and is negatively charged. Alteration of the electric field by bringing the hand near the tube is sufficient to displace the canal rays, whilst the beam of positive electrons, being apparently not electrified, remains unaffected.

The positive deviable beam cannot consist of ions, because these would be attracted by the cathode stream in the opposite direction to that which the beam in question actually takes. The attraction would, however, be small, and as a matter of fact the canal rays are but slightly deviated along with the cathode stream.

The two images formed on the willemite are not due to canal rays going partly through the ring cathode and partly round it. In one vacuum tube in which this was possible, the canal rays produced a phosphorescent image of the ring cathode on the willemite, but the other, a strong phosphorescent spot, was always present as well.

The deviable ray cannot consist of positive ions of low velocity, since positive ions travelling with the same E.M.F. (the canal ions) are already present, and are hardly deviable. The fact that the beam in question, after passing through the second cathode, is apparently no longer electrified, suggests that it is a combination of positive ions with negative electrons. Right, however, has shown (Atti R. Accad. Lincei, 1908, 17, 87) that such systems would, in a magnetic field, be deviated parallel to the lines of force.

Having failed to explain the phenomena by any recognised form of radiation, the author was led to consider the deviable rays as positive electrons liberated by the action of cathode rays on canal rays. The mechanism by which positive electrons are liberated is still obscure.
Perhaps they are grouped at the centres of atoms, and are attracted out by the atmosphere of cathode corpuscles. The negative electrons may act like projectiles against the positive ions which constitute canal rays.

The rapidity with which positive electrons disappear when they emerge from the atmosphere of negative electrons is surprising. The beam beyond the second cathode must be a flux of neutral material formed when the positive electrons disappear. The positive electrons may then have re-combined with the gas in the tube, but if the isolation of two kinds of electrons can be supposed to constitute the complete disintegration of matter, a bolder hypothesis is permissible, namely, that positive electrons combine directly with negative electrons, giving rise, perhaps, to hydrogen, which always appears in a Crookes tube.

R. J. C.

Ionised Gases. A. Blanc (Compt. rend., 1908, 147, 39–42).—The mobilities of positive and negative ions in mixtures of carbon dioxide with hydrogen or air in varying proportions have been measured by a modification of Rutherford’s alternating magnetic field method. It is found that the curves representing the inverse of the mobility in terms of the partial pressure of one of the gases in the mixture are in all cases straight lines. An equation is deduced theoretically connecting the mass of an ion with its mobility and the molecular composition of the mixed gases. From this it follows that if the effect of collisions between ions and molecules can be neglected, the mass of an ion must be of the same order as the mass of a molecule.

A positive or negative ion produced in carbon dioxide and travelling into air assumes the ordinary velocity of an ion produced in air.

The author supposes that an ion consists of a cluster of molecules which are constantly interchanged with the molecules of the surrounding gas. A carbon dioxide ion entering air, speedily becomes transformed into an air ion.

R. J. C.

Bose’s Phenomenon and the Laws of Contact Electrification. Édouard Guillaume (Compt. rend., 1908, 147, 53–55. Compare Bose, J. Physique, 1902, iv, 1, 481).—The production of an E.M.F. when a metallic thread immersed in an electrolyte is sharply twisted and the appearance of fatigue in this phenomenon have been further investigated.

If the wire is perfectly clean and the electrolyte is without action on it, no E.M.F. can be obtained by twisting the metal. Metals like copper and zinc when immersed in the electrolyte become covered with a thin, grey film. In such cases, twisting the wire produces a potential difference which is independent of the direction, but proportional to the angle of torsion. A number of twists at short intervals produce a gradually diminishing electrification. If a metal which is not superficially attacked by the liquid is covered with a thin, porous film, the same effects can be produced. Thus silver may be coated with its iodide, and platinum with gelatin or a burnt on film of kaolin.
The phenomena can be explained by Perrin's rules of contact electrification (see following abstract), which enable the relative effects of various electrolytes to be calculated with considerable accuracy.

R. J. C.

The Bose-Guillaume Phenomenon and Contact Electrification. Jean Perrin (Compt. rend., 1908, 147, 55—56).—The following explanation is given of the phenomena observed by Bose and by Guillaume (preceding abstract). When a wire covered with a thin, porous film is immersed in an electrolyte, the spongy sheath is electrified by contact along the whole of its enormous surface. The impregnating solution therefore contains an excess of ions of the opposite sign. When the wire is sharply twisted, the sheath is stretched, and a minute amount of the charged impregnating liquid is squeezed out into the external solution, leaving behind an excess of electricity of the opposite sign, which gives rise to a momentary E.M.F.

The extent and sign of the potential difference is determined by the nature of the contact electrification between the material of the film and the electrolyte. H$^+$ and OH$^-$ ions produce strong positive and negative effects, but are paralysed by multivalent ions of opposite sign.

Electrification by torsion is analogous with electrification by filtration through a porous diaphragm.

R. J. C.

Conduction of Electricity by Metals and Amalgams. Jenö Kinsky (Zeitsch. Elektrochem., 1908, 14, 406—410).—The experiments were intended to test the question whether positively-charged ions take any part in the transport of electricity through metals. Several copper and zinc cylinders with accurately-ground surfaces of contact were placed in contact and 5200 ampere hours passed through them, but no change in weight could be detected; iron and brass gave the same result. With silver and copper plates, no change of weight occurred, and the silver was quite free from copper both before and after the experiment. A large quantity of electricity was also passed through a tube containing homogeneous barium amalgam; after the experiment, the barium was found to be still quite evenly distributed throughout the tube. It appears, therefore, that positive ions take no part in the conduction of the current.

T. E.

Relation between Current and Potential Difference in Solutions of Iodine in Potassium Iodide. Experiments with Bright Platinum Electrodes. Erich Brunner (Zeitsch. physikal. Chem., 1908, 63, 487—506. Compare Abstr., 1907, ii, 223).—The experiments have been carried out in the same way as previously described (loc. cit.). Except in the neighbourhood of the cathodic limiting current, the values obtained for the polarisation are, as a rule, only a few millivolts greater than those observed at platinised electrodes. The results obtained at the unplatinised electrodes may be expressed by the formula $\varepsilon = \varepsilon_0 + I(\omega_0 + g\omega)$ (compare loc. cit.), where $g$ varies between 1 and 8, mostly between 2 and 5; during one experi-
ment, and generally also during a series of experiments made successively in different solutions, $q$ is fairly constant.

It is possible that the excess of the polarisation observed at unplatinised electrodes over that found at platinised electrodes is due to a surface resistance caused by cathodic polarisation, a resistance which vanishes as rapidly as it is produced. The excess, as far as can be seen, has nothing to do with chemical polarisation. J. C. P.

Thermodynamic Calculation of Electromotive Forces. FRANZ HALLA (Zeitsch. Elektrochem., 1908, 14, 411—414).—Nernst's theory of the relation between heat development and maximum work in reactions in condensed systems (Abstr., 1907, ii, 153) is tested for the case of the two reactions $2\text{Ag}+\text{PbCl}_2=\text{Pb}+2\text{AgCl}$ and $2\text{Ag}+\text{Hg}_2\text{Cl}_2=2\text{Hg}+2\text{AgCl}$, using existing data. Satisfactory agreement is found between the requirements of the theory and the facts. T. E.

Discharge Potentials of the Ions in Solutions of Alkali Alkylxides. GIACOMO CARRARA and ALDO BRINGHENTI (Gazzetta, 1908, 38, i, 698—708).—The anode potential curves of solutions of sodium methoxide in methyl alcohol and sodium ethoxide in ethyl alcohol exhibit characteristic points at 0.32—0.34 volt, referred to the potential of the decinormal calomel electrode as zero. These values, which differ so little in the two cases that they cannot be differentiated, represent the discharge potentials of the ions (OMe) and (OEt). Similar close agreement exists between the heats of formation of the corresponding sodium salts, and it is probable that the tensions of electrolytic decomposition of these salts are also nearly equal in value. Another less sharply marked point is shown by the anode potential curves between 0.60 and 0.65 volt; it is possible that this corresponds with the discharge potential of anions of small quantities of aldehydes or acids formed by the oxidising action of the platinised platinum in presence of air. The corresponding cathode potential curves exhibit a common characteristic point at 1.22 volts, which represents that of the sodium ion. T. H. P.

Stability of the Alternating Arc; a Function of the Atomic Weight of the Metallic Electrodes. CHARLES E. GUYE and A. BRON (Compt. rend., 1908, 147, 49—51).—It was shown in a recent paper (this vol., ii, 561) that the minimum potential required for a stable alternating arc largely depends on the period of extinction of the arc. This theory is now applied to elucidate the results of the authors' earlier researches on short metallic arcs.

Given the same current density, gap between electrodes, period of alternation, and air pressure, the voltage required to establish a stable arc increases regularly with the atomic weight of the electrodes. For example, with arcs 5 mm. long and current density 0.04 ampere per sq. centimetre of electrode, the voltages required are: carbon, 640; magnesium, 700; iron, 850; nickel, 850; copper, 870; silver, 900; cadmium, 725; platinum, 1000; gold, 1070. Cadmium is an exceptional case, as metallic vapour is largely produced, and the arc therefore requires an abnormally low voltage.
The period of alternation being 50, the arc is extinguished and re-lighted 100 times every second. The voltage required to re-light the arc must be the greater the more rapidly the electrodes cool at each extinction. The authors suppose that the cooling of the electrodes is for the most part the result of radiation, which is almost independent of the nature of the metal. Hence, as the specific heat is inversely as the atomic weight (Dulong and Petit), the higher the atomic weight the smaller the heat content of the electrodes, the quicker the cooling, and the higher the voltage required to re-light the arc.

It may also happen that electrons projected from the incandescent cathode have a velocity which is higher the higher the atomic weight. The two explanations are not mutually exclusive. R. J. C.

Chemical Reactions in a Magnetic Field. G. Berndt (Physikal. Zeitsch., 1908, 9, 512—519).—The influence of a magnetic field on the heat development which accompanies the solution of iron in hydrochloric and sulphuric acids has been examined. The apparatus employed consisted of an electromagnet with square pole-pieces, between which a magnetic field of intensity equal to 3000 Gauss could be established. Two silvered Dewar vessels, packed in cotton-wool, were placed between the pole-pieces, and by means of a nickel-copper thermo-element the difference of temperature between the contents of the two vessels was read off at frequent intervals. One Dewar vessel served for the solution process, and the other acted as a blank to eliminate, as far as possible, temperature changes not due to the passage of iron into solution.

The estimated accuracy of the measurement of the difference between the heat of solution with and without a magnetic field is 1%, and to this extent the experimental data lead to the conclusion that a magnetic field has no influence on the amount of heat developed by the solution of iron in hydrochloric or sulphuric acids. It is shown that the differences previously obtained by Nicholls (Abstr., 1886, 668) are due to secondary disturbances, and that, although it has been shown by Duhem that the development of heat in a magnetic field should theoretically be less than without a field, the difference in question is too small to be experimentally measured.

One difference between the two processes is that the rate of solution in a magnetic field is smaller, and this is attributed to the fact that the iron particles do not respond so readily to the mechanical disturbances resulting from the evolution of gas. The protection of the iron from the action of the acid by the chloride formed may also contribute to the slower rate of solution in the magnetic field.

Experiments with zinc show that the heat change and the rate of solution are not influenced by a magnetic field. H. M. D.

Relation between Magnetic and Chemical Properties of Complex Ferric Salts. P. Pascal (Compt. rend., 1908, 147, 56—58).—The magnetic susceptibilities of a number of solutions of ferric compounds containing the same weight of iron per litre have been determined by the well-known U-tube method. It is found that as the condition of the iron is more and more removed from
the ordinary (precipitable) ferric state, the solutions become more and more diamagnetic. The gradual addition of acid to ammoniacal ferric pyrophosphate is accompanied by a corresponding increase in paramagnetism, even before the solution has attained to the ordinary ferric colour. Excess of alkali, on the other hand, accentuates the diamagnetism of a ferripyrophosphate.

Ferrimetaphosphates and ferripyrophosphates exhibit the phenomenon of magnetic double refraction.

R. J. C.

Orientation of Crystals by the Magnetic Field. Importance of Optical Properties of Mixed Liquids from the Point of View of Crystalline Symmetry. A. Cotton and Henri Mouton (Compt. rend., 1908, 147, 51—53. Compare Abstr., 1906, ii, 146; 1907, ii, 727).—The magnetic susceptibility of a crystal in various directions may be represented by an ellipsoid. Electrical and optical properties are also represented by ellipsoids. Although the relation between the ellipsoids cannot be generally stated, the elements of symmetry of the crystal belong to all three. Crystalline fragments suspended in a liquid in a metallic field will tend to set themselves with the long axis of their magnetic ellipsoid parallel to the lines of force. In an electric field, the long axis of the electric ellipsoid will set itself parallel to the lines of force. Crystals fall into two groups, according as the long axes of their magnetic and electric ellipsoids coincide or not. If, as in the case of the unaxial system, the two long axes do not coincide, suspended crystals will be completely oriented by the application of electric and magnetic fields at right angles, and the liquid with its suspended crystals will be isotropic in the direction of one of the fields. Some information concerning the crystallographic properties of microscopic crystals can thus be obtained.

The author combats the conclusion of Meslin (Compt. rend., 1908, 146, 1305) that the orientation of a suspended crystal by a magnetic field can alter with variation in the permeability of the suspending liquid.

R. J. C.

Glass Thermostats for Higher Temperatures. H. W. Fischer and O. Bobertag (Zeitsch. Elektrochem., 1908, 14, 375—376).—For temperatures above 100°, a large glass beaker containing 10 litres of paraffin oil is used; this is heated by a "cryptol" resistance enclosed in a glass tube. For temperatures below 100°, a glass vessel full of water is used; a stream of hot water, from a reservoir at constant head, flows into the vessel through a copper spiral heated by a gas flame, which is regulated by an ordinary regulator.

T. E.

Density and Latent Heat of Fusion of Ice, and the Molecular Depression of the Freezing Point in Aqueous Solutions. W. A. Roth (Zeitsch. physikal. Chem., 1908, 63, 441—446).—A critical review of the determinations of these constants recorded by various workers. The author considers the following to be the most probable values: for the density of ice at 0°, 0·9168; for the latent heat of fusion, 79·67 cal., the calorie being defined as the heat necessary to raise 1 gram of water from 15° to 16°; for the molecular depression of the freezing point, 1·858°.

J. C. P.
Solidification Phenomena Exhibited by Inorganic Salts and Salt Mixtures. Wilhelm Plato (Zeitsch. physikal. Chem., 1908, 68, 447—457. Compare Abstr., 1906, ii, 521; 1907, ii, 239).—Further observations are recorded bearing on the author’s method of calculating the latent heat of fusion from the special form of cooling curve described previously (loc. cit.). It appears that the formula based on the earlier results may be simplified. It is shown, also, that the latent heat of fusion may be deduced from the area enclosed by (1) the actual cooling curve, and (2) the curve that would be traced if no solidification took place.

J. C. P.

Specific Heat of Barytes, Witherite, and Fused Lime. Latschenko (Compt. rend., 1908, 147, 58—61).—The amounts of heat required to raise 3 to 7 grams of these substances from the room temperature to upwards of 1050° have been determined by the calorimetric method.

The specific heat of barytes increases regularly from 0.114 at 150° to 0.129 at 500°, remaining practically constant at higher temperatures.

Witherite undergoes a molecular transformation at about 800°, accompanied by a sudden increase of 19 calories per gram in the total heat of warming and a noteworthy change in the specific heat.

Values obtained with fused lime point to the existence of a molecular transformation at 405—410°, accompanied by an absorption of 5 calories per gram. Lime fused in the electric furnace gives good results only on the first occasion that it is plunged into the calorimeter water, as successive wettings and heatings break up the surface. Consistent results were obtained by the use of petroleum in the calorimeter.

R. J. C.

Thermochemical Evidence for von Baeyer's Strain Theory. H. Stanley Redgrove (Chem. News, 1908, 98, 25—27).—A theoretical paper on the thermal behaviour of the hydrocarbons, molecular heats of combustion of which have been determined by Thomsen and Strohmann, considered in the light of Baeyer’s strain theory. Values for the thermal equivalent of double and treble linkings are deduced, and the thermal equivalent of strains in polymethylene compounds is found to be proportional to the angle of deviation of the carbon atoms. From thermal data, the conclusion is drawn that the molecular heat of formation found for ethylene oxide and that deduced are quite in accord with the strain theory; the heat equivalent of the molecular strain in this compound is given as 18.0 cals.

J. V. E.

Explanation of the Viscosity Curve for Mixtures of Glycerol and Water. José R. Carracido (Anal., Fis. Quim., 1908, 6, 320—321).—The viscosity curve obtained by plotting the values given by Martínez-Strong (this vol., i, 307) shows a critical point between the concentrations 60% and 70% of glycerol, beyond which the viscosity increases very rapidly. Examined with the ultra-microscope, solutions containing less than 50% of glycerol do not show luminous points, and present the appearance of true
solutions; solutions containing from 50\% to 80\% of glycerol show an increasing number of such points, and probably consist of a mixture of a true solution with colloidal glycerol in a state of pseudo-solution. Mixtures containing 90—100\% of glycerol do not show points of light, and probably consist of liquid hydrogels which are completely homogeneous.

W. A. D.

Osmotic Pressure of Dextrose Solutions at 10\°. HARMON N. MORSE and W. W. HOLLAND (Amer. Chem. J., 1908, 40, 1—18. Compare this vol., ii, 671).—At 10\°, the osmotic pressures of dextrose solutions are proportional to the concentrations, the maximum, minimum, and mean molecular pressures obtained for individual concentrations being 23·87, 23·70, and 23·80 atmospheres respectively. The excess of osmotic over gas pressure observed in the neighbourhood of 0\° (loc. cit.) does not disappear at 10\°, at which temperature the mean molecular gas pressure is 23·09 atmospheres. The mean value of the ratio of osmotic to gas pressure for 0·1N to 1·0N dextrose solutions at 10\° is 1·031, the limiting values of the ratio being 1·035 and 1·027. The closer approximation of osmotic to gas pressure at 10\° than at 0\° is due more to the increase in gas pressure between these temperatures than to augmentation of osmotic pressure, the mean increases in molecular gas and osmotic pressures being 0·81 and 0·35 atmosphere respectively.

The following table summarises the results obtained up to the present time:

<table>
<thead>
<tr>

T. H. P.

Explosive Crystallisation. FRANK E. WESTON (Chem. News, 1908, 98, 27).—The author finds that when an aqueous solution of the compound formed by the combination of a sulphite with a thiosulphate is evaporated in a partial vacuum, a stage of concentration is reached when crystallisation may be accompanied by explosive violence. It seems probable in the case of the evaporation of some sulphites that crystallisation is suddenly induced on the surface with a consequent sudden increase in the vapour pressure of the surrounding liquid, which under the very low pressure existing causes the liquid to boil violently.

J. V. E.

Theory of Dyeing. HUGO FISCHER (Zeitsch. physikal. Chem., 1908, 63, 480—486).—In criticising Freundlich and Losev's theory of adsorption (Abstr., 1907, ii, 534), the author argues against assuming the existence of internal surfaces in colloids. He maintains that the swelling of colloidal substances cannot be explained by reference to any sort of structure. The phenomena of swelling and of dye absorption alike are, in the opinion of the author, essentially solution phenomena. Experiments are quoted which support this view.

J. C. P.
Influence of the Medium on Brownian Motions. **Victor Henri** (*Compt. rend.*, 1908, 147, 62—65).—Rubber latex is coagulated to a network of fine threads by addition of acids, but is aggregated by alkalis to a mass of irregular granules without definite structure. Before coagulation sets in, the Brownian motion of the particles in the emulsion is retarded.

The author has made cinematographic photomicrographs of rubber latex diluted to 1 in 500 with water in presence of quantities of hydrochloric acid, acetic acid, sodium carbonate, carbamide, and alcohol too small to bring about coagulation. With alkali, the Brownian movements are twice as slow, and with acid nine times as slow, as in distilled water. Thus the average displacement of a particle in 1/20 second was 0.62 μ in water, 0.31 μ in N/10 sodium carbonate, and 0.07 μ in N/32 hydrochloric acid. N/100 acetic acid produced the same effect as N/32 hydrochloric acid, although the former is a weaker coagulating agent.

The action cannot be attributed to the electrical influence of the ions, because alcohol produces an effect which is as intense as that of acid. On the other hand, carbamide, which does not coagulate the latex, also produces no change in the Brownian movement.

Measurements show that the granules absorb alkali somewhat, and acid very strongly. The author supposes that an adsorption zone containing molecules of the coagulating agent is formed round each granule, and that this surface combination is the cause of the slackening in the Brownian motion of the granules. **R. J. C.**

Osmotic Pressure and Brownian Motion. **Jacques Duclaux** (*Compt. rend.*, 1908, 147, 131—134).—Colloidal solutions and very fine suspensions have been shown to possess an osmotic pressure. This has been explained on kinetic grounds, but the osmotic pressures calculated on the kinetic theory are systematically smaller than the experimental values, although of the same order. The recent work of Perrin (*Compt. rend.*, 1908, 146, 967), which leads to an almost absolute agreement between experiment and the kinetic hypothesis, is criticised. The material employed by Perrin (namely, gamboge) is not entirely insoluble, so that in the emulsions which he prepared probably some 23% of the material was in solution. Furthermore, the insoluble particles were not conclusively shown to be of uniform size, and the method of enumerating them was questionable. Thus the kinetic theory does not explain the whole of the osmotic pressures. It is also inferior to the electrification theory of colloidal solutions in explaining many other properties, particularly coagulation.

The author supposes that the osmotic pressure of a colloidal solution is the same as that of an ordinary electrolytic solution containing the same number of electrons in the condition of free ions. It must be assumed that an ion exercises the same osmotic pressure whether free or as part of the layer on an electrified granule.

The charge can be recognised by the conductivity of the granules, that is, the difference in conductivity before and after filtering the colloidal solution through collodion. Knowing the velocity of the granules, their charge, the number of ions surrounding them and the corresponding osmotic pressures can be calculated.
The author has experimented with a true colloid, ferric hydroxide, and results calculated for osmotic pressure from the conductivity are of the same order, but somewhat smaller than the experimental values. The electrical theory gives results which are quite as good as those given by the kinetic theory, and is based on experiments made with a true colloidal solution instead of with a mere suspension, the properties of which in spite of several analogies are not the same. There is nothing incompatible in the two methods of treatment, however, if the kinetic theory is correctly regarded. R. J. C.

Ammonia Equilibrium. F. Jost (Zeitsch. Elektrochem., 1908, 14, 373—375).—The author points out that the discrepancy between his measurements and those of Haber and Le Rossignol (this vol., ii, 362) is not very great at the lower temperatures. Up to 80° a difference of less than 40° in the measurement of temperature would account for it. The possible error of his own measurements is estimated at about 20°. At higher temperatures, the differences are larger, and it is suggested that in Haber's measurements the equilibrium may have been displaced towards the cooler part of the quartz tube. T. E.

Experimental and Thermodynamic Researches on Neutral Salt Action. Bohdan von Szyszkowski (Zeitsch. physikal. Chem., 1908, 63, 421—440. Compare Abstr., 1907, ii, 238).—When carbon dioxide is passed through water containing ultramarine in suspension, hydrogen sulphide is liberated. The presence of neutral salts hinders this reaction, and there appears to be for each salt a concentration which is just sufficient to prevent any discoverable liberation of hydrogen sulphide. The author has determined these limiting concentrations in a number of cases, and regards the reciprocal of this concentration as a measure of the neutral salt action. It is found in this way that sodium salts exert a much stronger neutral salt action than potassium salts. When sodium salts alone are considered, it appears that the neutral salt action increases with the combining weight of the anion; this rule does not apply in the case of the potassium salts. As regards the comparative neutral salt action of sodium chloride and nitrate and potassium chloride and nitrate, the results of this investigation are in harmony with the author's earlier work (loc. cit.). There appears to be no immediate connexion between neutral salt action and the influence of the salts on gas solubility. A few experiments made with alcohol show that the general character of neutral salt action is manifest also in alcoholic solutions.

As a practical result of his work, the author advocates a method of testing the quality of a specimen of ultramarine. A sample of the best quality, suspended in a 1·4 N solution of sodium chloride and exposed to a fairly strong current of carbon dioxide, should not liberate any hydrogen sulphide.

The influence of a neutral salt, such as sodium chloride, on the behaviour of a weak electrolyte, such as carbonic acid, is discussed in general terms on a thermodynamic basis.

J. C. P.
Velocity of the Reaction between Bromine and Benzaldehyde. WALTER HERZ and HERMANN DICK (Ber., 1908, 41, 2645—2648).—In connexion with experiments on the velocity of the addition of bromine to unsaturated substances in various solvents, the reaction $2\text{PhCHO} + \text{Br}_2 = \text{PhCO}_2\text{CHPhBr} + \text{HBr}$ has been examined in chloroform, carbon disulphide, and carbon tetrachloride. The value of $K$, calculated for a bimolecular reaction, is almost the same and independent of the concentration in the first two solvents, but is about one thousand times as great in carbon tetrachloride.

C. S.

Inorganic Chemistry.

Hydrogen Persulphide. RUDOLF SCHENCK and V. FALCKE (Ber., 1908, 41, 2600—2603. Compare Bloch and Höhn, this vol., ii, 579, 580).—The authors have obtained the trisulphide $\text{H}_2\text{S}_3$ by distilling the crude polysulphide under diminished pressure. It is essential to blow steam through the glass vessels, and also to boil them in sulphuric acid, in order to remove the alkali from the surface, otherwise the polysulphide decomposes during distillation. It is a colourless, strongly refracting liquid, b. p. $43\text{—}50^\circ/4.5$ mm., $D^{15} 1.496$, and $n_\rho$ over 1.70. Its odour resembles that of camphor, and of the product formed by the slow combustion of sulphur. The substance is extremely volatile, and dissolves in most organic solvents, but these solutions are unstable, with the exception of that in bromoform. Analyses and molecular weight determinations agree with the formula $\text{H}_2\text{S}_3$.

J. J. S.

The Polyiodide Molecule. PIO LAMI (Boll. chim. farm., 1908, 47, 435—441).—A theoretical paper. From the solubility of iodine in potassium iodide solutions of various strengths, and from the electrical conductivity of potassium iodide solutions, it is deduced that undissociated potassium polyiodide has the composition $\text{KII}_3$, and that it dissociates into the ions $\text{K}$ and $\text{II}$.

No reference is made to the work of Jakowkin (Abstr., 1894, ii, 271; 1896, ii, 514; compare also Dawson, Trans., 1908, 93, 1308).

G. B.

So-called Crystalline Boron. HEINRICH BILTZ (Ber., 1908, 41, 2634—2645).—Crystalline silicon can be obtained by Kühne’s method (D.R.-P. 147871), but the directions for the preparation of crystalline boron do not give successful results. The author uses the following method. An intimate mixture of boron trioxide (50 grams), sulphur (75 grams), and aluminium (100 grams), or magnesium powder, is fired by a piece of magnesium ribbon. After the reaction, the fused mass is decomposed by water, the globules of aluminium separated, and
treated with hydrochloric acid. The residual black, crystalline powder is treated successively with concentrated hydrochloric acid, hydrofluoric acid, and dilute hydrochloric acid for many days. When larger quantities of materials are to be used, the proportions must be altered, more aluminium and less sulphur being taken; the yield is smaller and the black crystals are not so large. The preparation is practically an individual substance, has $D'_4 = 2.554 \pm 0.005$ (by the floating method), and consists of monoclinic crystals $[a : b : c = 0.7130 : 1 : 0.7139]$. A complete analysis of the substance proves it to be aluminium boride, $\text{AlB}_2$ (compare Hampe, this Journ., 1877, i, 273). It is identical with the black modification of crystalline boron obtained by Wöhler and Deville (Annalen, 1858, 105, 68), the specimens of which, however, contained carbon as an impurity. The yellow, transparent crystals mentioned by these investigators have also been obtained by the preceding aluminothermic method, and will be discussed later.

C. S.

**Presence of Rare Gases in the Atmosphere at Different Heights.** L. Teisserenc de Bort (Compt. rend., 1908, 147, 219—221).—Samples collected at Trappes from the upper regions of the atmosphere have been examined spectroscopically after removal of oxygen, nitrogen, and argon. The latter gas occurred in notable proportions. The samples collected up to a height of 10 kilometres contained both helium and neon, but helium was not detected in a sample obtained at 14 kilometres.

W. O. W.

**Acid Sulphates of Potassium.** L. Arzalier (Compt. rend., 1908, 147, 129—131).—On evaporation of a dilute solution containing molecular proportions of sulphuric acid and potassium sulphate, there are formed various acid salts, as described by Marignac, and also crystals of the composition $4\text{K}_2\text{SO}_4,3\text{H}_2\text{SO}_4,\text{H}_2\text{O}$, which, however, from their heat of solution do not appear to be a definite compound.

From concentrated sulphuric acid and normal potassium sulphate, the salts $\text{K}_2\text{SO}_4,3\text{H}_2\text{SO}_4,\text{H}_2\text{O}$ and $\text{K}_2\text{SO}_4,3\text{H}_2\text{SO}_4,3\text{H}_2\text{O}$ were prepared, which, when heated in an inert gas to 150°, yield the salt,

$$\text{K}_2\text{SO}_4,3\text{H}_2\text{SO}_4,$$

previously obtained by Schultz in an impure state.

G. B.

**Thioantimonates of Alkali Metals.** I. A. D. Donk (Chem. Weekblad, 1908, 5, 529—551).—From aqueous solutions, the following hydrated thioantimonates of sodium, potassium, ammonium, and lithium have been isolated: $\text{Na}_3\text{SbS}_4,9\text{H}_2\text{O}$; $\text{K}_3\text{SbS}_4,6\text{H}_2\text{O}$; $\text{K}_3\text{SbS}_4,5\text{H}_2\text{O}$; $\text{K}_3\text{SbS}_4,3\text{H}_2\text{O}$; $(\text{NH}_4)_3\text{SbS}_4,4\text{H}_2\text{O}$, and $\text{Li}_3\text{SbS}_4,10\text{H}_2\text{O}$. From aqueous-alcoholic solutions, the following have been isolated: $\text{Na}_3\text{SbS}_4,9\text{H}_2\text{O}$; $\text{K}_3\text{SbS}_4,6\text{H}_2\text{O}$; $\text{K}_3\text{SbS}_4,3\text{H}_2\text{O}$; $(\text{NH}_4)_3\text{SbS}_4,4\text{H}_2\text{O}$, and $\text{Li}_3\text{SbS}_4,10\text{H}_2\text{O}$.

A. J. W.
Reaction between Ammonium Persulphate and Sodium Peroxide. R. Kempf and Ed. Oehler (Ber., 1908, 41, 2576—2580. Compare Abstr., 1906, ii, 19, 25).—The fact that when an aqueous alkaline solution of ammonium persulphate is kept for some time the ammonia formed is quantitatively oxidised to nitric acid, whereas when silver peroxide is present the main oxidation product is nitrogen, is accounted for by the different velocities of the two reactions, the latter being much more rapid than the former. If the first reaction is accelerated by raising the temperature, nitrogen is also formed.

Ammonium persulphate and sodium peroxide react readily. When the dry substances are rubbed together in a mortar, the mixture explodes, producing thick fumes. The same result is obtained by heating the mixture, by passing a stream of carbon dioxide over it, or by the addition of a drop or two of water. The temperature at which the explosion occurs lies between 75° and 140°, and depends on the rate of heating and the amount of moisture present. The gases evolved consist of nitrogen and oxygen, but the proportions vary considerably in different experiments.

The mixture is not explosive when the peroxide is replaced by sodium hydroxide, or the ammonium persulphate replaced by ammonium sulphate, sodium persulphate, or a mixture of the two.

J. J. S.

Hydrates of Baryta and Strontia. Robert de Forcrand (Compt. rend., 1908, 147, 165—169. Compare this vol., ii, 155, 493).—The hydrate SrO,0.22H₂O slowly loses water in a vacuum desiccator at 10° and, after a week, has the composition SrO,0.2H₂O. When left in a vacuum for a month, this is converted into SrO,0.15H₂O. The dihydrate, the existence of which has hitherto been questioned, is also formed by heating SrO,0.2H₂O for two hours at 45—50° in a stream of dry hydrogen; if the operation is carried out at 95°, the mono-hydrate is obtained in the same time, and this does not undergo further dehydration below 540°. At this temperature, however, water is lost until the product has a composition varying between SrO,0.22H₂O and SrO,0.06H₂O. This has been mistaken by previous authors for anhydrous SrO, but it probably consists of a mixture of condensed hydrates. Anhydrous strontium oxide can only be obtained by heating this mixture to 850° for several hours.

The hydrate BaO,0.9H₂O undergoes a somewhat similar series of changes when heated. The dihydrate, however, does not change into the monohydrate below 90—95°. BaO,0.9H₂O has m. p. 325°, and does not lose water below 660°. When maintained at this temperature for several days, it becomes anhydrous; the change, however, is complete in two or three hours at 780°. There is no evidence for the existence of any compound intermediate between the monohydrate (hydroxide) and the oxide.

A table is given showing the heats of formation and heats of solution of the foregoing hydroxides and oxides in water, calculated from their heats of dissolution in dilute aqueous hydrogen chloride. The heat of solution for 1 gram molecule of SrO in 20 litres of water
at $15^\circ$ is 29.76 Cal., and not 30.8 Cal. as previously stated by the author (loc. cit.). From these data, the following conclusions are drawn: (1) The conversion of SrO$\cdot$H$_2$O into SrO is more difficult than the conversion of BaO$\cdot$H$_2$O into BaO. (2) SrO$\cdot$9H$_2$O and BaO$\cdot$9H$_2$O should dissociate at 142$^\circ$ and 152$^\circ$ respectively, whereas the actual temperatures of dissociation are 102$^\circ$ and 107$^\circ$. The difference of 40—50$^\circ$ is due therefore to an endothermic condensation of the molecule on the formation of the dihydrate. A further endothermic condensation occurs on the conversion of the dihydrate into the monohydrate. (3) The oxides should be represented as (SrO)$_n$ and (BaO)$_n$.

W. O. W.

Action of Hydrochloric Acid on Manganese Dioxide. Willis B. Holmes and E. V. Manuel (J. Amer. Chem. Soc., 1908, 30, 1192—1193. Compare Abstr., 1907, ii, 873).—The authors cannot as yet confirm the existence of manganese tetrachloride, although they have some evidence of the formation of a compound richer in chlorine than the trichloride.

L. de K.

Colour and Composition of Guignet’s Green. Lothar Wöhler and W. Becker (Zeitsch. angew. Chem., 1908, 21, 1600—1606).—Scheurer-Kestner’s statement is confirmed (Dingl. Polyt. J., 1865, 176, 386), that the boron present in Guignet’s green is without influence on the colour, and is present only as a remnant of the chromium borate formed primarily by fusion of potassium dichromate with boric acid. By employing ammonium, instead of potassium, dichromate, Guignet’s green is readily obtained free from boron, and has then the composition, Cr$_4$O$_8$ (OH)$_6$, ascribed to it by Scheurer-Kestner. The product obtained on heating potassium dichromate with an excess of boric acid has the composition Cr$_4$O$_8$ (B$_3$O$_7$)$_3$.

Whilst Guignet’s green has a vapour tension of 13 mm. at 75$^\circ$, 16 mm. at 81$^\circ$, and 26 mm. at 86$^\circ$, the greyish-violet chromium hydroxide, which has the same composition, is found to have a vapour tension of only 2 mm., not increasing between 75$^\circ$ and 93.4$^\circ$. This small vapour tension may result from the presence of moisture. These differences and the difference in colour of the two hydrates are ascribed to isomerism. The greyish-violet hydroxide is converted into its brilliant green isomeride on prolonged heating with water at 250$^\circ$. G. Y.

Oxalate Reduction of Alkali Iridiochlorides. Marcel Delépine (Compt. rend., 1908, 147, 198).—A reply to Vézes’ claim to priority (this vol., ii, 703).

W. O. W.

Mineralogical Chemistry.

Fumaroles of Etna. Boric Acid in the Fumaroles of Vesuvius. Alfred Lacroix (Compt. rend., 1908, 147, 161—165).—The fumaroles of the recent (1908) eruption of Etna are of the same types as those of Vesuvius, but they are much less active; this is due
to the short period of the eruption, and to the fact that the magma was poor in volatile materials. The types specially described are: (i) fumaroles depositing alkali chlorides; (ii) those emitting hydrogen chloride and depositing kremersite, &c., and (iii) those depositing ammonium chloride alone. The crusts of ammonium chloride were found to contain small amounts of fluorine, perhaps present as an alkali silicofluoride.

In one of the fumaroles of the 1906 eruption of Vesuvius, a small amount of sassolite \((H_3BO_3)\) in crystalline scales was detected. This is rare at Vesuvius, but its presence is of importance in connexion with theories of pneumatolytic action.

L. J. S.

Lavas of the Recent Eruption of Etna. Alfred Lacroix (Compt. rend., 1908, 147, 99—103).—The various products of the 1908 eruption of Etna were examined petrographically and chemically. They closely resemble one another in chemical composition and in the porphyritic crystals (of basic plagioclase, little augite and magnetite, and very little olivine) which they contain. The rock of a lava flow (anal. I) which has cooled more slowly, and has consequently crystallised more completely, contains in its ground-mass microlites of augite and olivine with very little glass; this rock is a basalt, or, according to the French terminology, a labradorite. In a slightly scoriaceous product (anal. II) of eruptions of the Strombolian type, and in a highly scoriaceous bomb (anal. III) resulting by an explosion of the Hawaiian type, the ground-mass contains more glassy material. Anal. IV is of the ash which fell during the eruption:

L. J. S

Physiological Chemistry.

Blood-coagulation Time. F. L. Golla (Proc. physiol. Soc., 1908, lxi—lxii; J. Physiol., 37).—A modification of Buckmaster’s coagulometer is described; it gives very constant results with a given blood. The coagulation time does not exhibit diurnal variation; it is not altered by fasting, or by the internal administration of sodium citrate or calcium salts. Nor is it abnormal in hæmophilia (1 case), purpura (1 case), or urticaria (2 cases). It is markedly prolonged in cases of jaundice, probably because of an alteration in the surface tension of the blood-film.

W. D. H.
Effect of Amyl Nitrite on Red Blood Corpuscles. GR. SLAVU
(Compt. rend., 1908, 147, 148—149).—Less than 0·3% of amyl nitrite
does not produce a visible spectroscopic change in the blood. Death,
after toxic doses have been administered, is not wholly due to want of
oxygen, for a considerable quantity of the gas can be extracted from
the blood in a vacuum. The oxygen which is set free, both in vivo and
in vitro, is not derived from the plasma, but from the corpuscles.
G. B.

The Behaviour of the Sugar of the Blood after Bleeding.
NILS ANDERSSON (Biochem. Zeitsch., 1908, 12, 1—7).—The statement
that the amount of sugar in the blood increases after bleeding is
confirmed; this occurs in rabbits, especially after a second bleeding.
The blood-sugar consists of 75% dextrose, and the remaining 25% is
spoken of as residual sugar; it is not fermentable by yeast and gives
a positive orcinol reaction, and so is probably a pentose, but this
requires confirmation. Both varieties of sugar increase in the same pro-
portion after bleeding; the total amount may be more than doubled.
W. D. H.

The Blood Issuing from the Dog's Suprarenal. F. A. YOUNG
—The blood issuing from the suprarenal gland, especially if it has been
dammed back there for a time by a ligature, produces on injection
into the general blood stream a decided rise of pressure, and so
presumably contains adrenaline.
W. D. H.

Duration of Effect of Pituitary Extract on Blood Pressure.
P. LOCKHART MUMMERY and W. LEGGE SYMES (Proc. physiol. Soc.,
1908, lvi; J. Physiol., 37).—In the dog, the elevation of blood pressure
produced by injection of pituitary extract may last twenty to thirty
minutes; in the pithed cat, it may persist for many hours.
W. D. H.

Influence of Magnesium Sulphate on Metabolism. MATTHEW
STEEL (J. Biol. Chem., 1908, 5, 85—124).—Injection of magnesium
sulphate into a muscle, or under the skin, does not cause diarrhoea.
The total nitrogen eliminated is somewhat increased, but the most
marked effect is the rise, relative and absolute, in urinary ammonia.
W. D. H.

Tolerance to Alcohol. JOSEF PRINGSHEIM (Biochem. Zeitsch.,
1908, 12, 143—192).—In animals accustomed to alcohol, the same
quantity is excreted by lungs, kidneys, and skin as in those
unaccustomed to its use. In both classes of animals, the faces are
free from alcohol. In both groups the amount united to glycuronic
acid in the urine is the same, but that united to sulphuric acid is
slightly higher in the "accustomed" animals. The "accustomed" animals
burn off the alcohol more rapidly, that is, in about two-thirds
of the time occupied in the burning by the "non-accustomed" group.
In acute alcoholic poisoning, the percentage of alcohol in the body is
about 66% more in the "non-accustomed" animals. The seat of combustion is mainly the liver, then comes heart muscle, and the brain is last.

W. D. H.

Temperature-coefficients of Velocities of Various Physiological Actions. CHARLES D. SNYDER (Amer. J. Physiol., 1908, 22, 309—334).—The large number of observations recorded and tabulated show that the temperature-velocities are all of magnitudes similar to those seen in physical and chemical reactions; in cases where it is known that metabolism occurs, the coefficients observed are those of chemical reactions; under this category are included the shortening of muscle, the latent period of smooth muscle, &c. Coefficients lower than these simulate physical actions, for instance, the latent period of striated muscle. In still other cases, the data are insufficient to draw conclusions from, as, for instance, the latent period of cardiac muscle and of vagus stimulation, and the velocity of urinary secretion and of lymph formation.

W. D. H.

Effects of Variations in Inorganic Salts and Reaction on Plants and Animals. BENJAMIN MOORE, HERBERT E. ROAF, and ROBERT E. KNOWLES (Bio-Chem. J., 1908, 3, 279—312).—The range of ionic concentrations compatible with life is a narrow one. Short of the lethal dose, life and growth of plants are stimulated by alkali and not by acid. Potassium is more stimulating than sodium to both rootlets and flowers. The phosphatic anion causes increase in size, but irregularities in the flowers. In amphibia, both acid and alkaline phosphates increase growth. Higher concentrations cause death, which in the case of the alkaline salt is preceded by hyperexcitability. In mammals, alkaline and acid phosphates, in doses of 0.26—0.38 gram per kilo. of body-weight, cause increased metabolism, diminishing body-weight, and finally death. The adipose and muscular tissues waste considerably; other symptoms are polyuria, and with large doses, diarrhoea with ulceration of the alimentary canal, leucocytosis, degeneration of liver cells, and nephritis. The alkalinity of the serum is increased by the alkaline and diminished by the acid salt.

W. D. H.

Chemical Composition of the Herring during the Reproductive Period. THOMAS H. MILROY (Bio-Chem. J., 1908, 3, 366—390).—The herring undoubtedly feeds until spawning time, and so differs from the salmon; the herring is therefore not dependent on its muscle proteins for the growth of its ovaries. In the male, as in the female, the highest fat percentage is found in the muscles just before rapid growth of the reproductive organs occurs; then it falls. The year may be divided into three periods: (1) The restitution or feeding period, three to four months before spawning; the spent fish recovers and accumulates a store of fat. (2) The ripening period, six to seven months. The fish still takes food, but in less amount, and the sexual organs grow as the store of muscle fat lessens. (3) The spawning period, two months; during this time feeding stops, the fat in the muscles falls greatly, and the water increases.

W. D. H.
Glycogen of Frog's Spawn. E. Haensel (Biochem. Zeitsch., 1908, 12, 138—142).—Glycogen is present in frog's spawn in amounts varying from 0·016 to 0·052% of the fresh, or from 1·28 to 4·08% of the dry, material. The estimations were made by Pflüger's method. The addition of dextrose, lactose, or sucrose to the spawn causes a rise in the yield of glycogen.

W. D. H.

Influence of Strontium on the Growth and Composition of Bone. Helene Stoeltzner (Biochem. Zeitsch., 1908, 12, 119—137).—The experiments recorded on growing dogs show that if the diet is poor in calcium, or if the calcium is partly replaced by strontium, the bone condition that results differs from that seen in rickets; in the latter condition, the relationship of calcium to fat-free dry substance is lessened, but this was not the case in the experimental puppies. Strontium is laid down in the bone in relatively important amount, but it does not seem able to take the place of calcium in producing healthy bone.

W. D. H.

Chemistry of Muscle and Liver of Reptiles. John F. Lyman (J. Biol. Chem., 1908, 5, 125—127).—Four kilograms of fresh muscle and the livers from two pythons were examined. From the muscle, creatine and sarcolactic acid were separated and identified. The most conspicuous purine derivative is hypoxanthine, as in higher vertebrates.

From the livers, uric acid, guanine, and adenine were obtained. Xanthine and hypoxanthine could not be separated in amounts sufficient for identification.

W. D. H.

Contraction of Muscle in Relation to the Presence of Receptive Substances. II. John N. Langley (J. Physiol., 1908, 37, 165—212. Compare this vol., ii, 120).—Further details of the phenomena of nicotine poisoning in frog's muscle, which support the author's previous contention that there exist in the muscle, or its nerve-endings, or both, substances with which the nicotine combines.

W. D. H.

W. D. H.

Kidney Secretion of Indigo-carmin, Methylene-blue, and Sodium Carminate. George D. Shaffer (Amer. J. Physiol., 1908, 22, 335—352).—The experiments recorded confirm Heidenhain's views on urinary formation; indigo-carmin, leuco-indigo-carmin, and methylene-blue are secreted at varying rates by the convoluted tubules and the wider limb of Henle's loop. Sodium carminate, on the other hand, passes out by the glomeruli.

W. D. H.

[Symptomatic] Significance of Urinary Indoxyl. Detection of Indole in Pus. Charles Porcher (Compt. rend., 1908, 147, 214—217).—Pus, diluted with water and made alkaline, is distilled with steam; the indole is extracted from the distillate by pure
benzene, in which it is detected by the colour reaction with \( p \)-dimethyl-aminobenzaldehyde. In less than half the number of specimens examined, indole was present; its formation seems to depend on the presence of particular organisms.

G. B.

Renal Calculi. J. Sydney Rowlands (Bio-Chem. J., 1908, 3, 346—350).—A series of twenty-two calculi from South-west Lancashire and North Wales was examined. The commonest constituent was found to be calcium oxalate. Uric acid was rare, and was absent in nineteen cases.

W. D. H.

Concentration of Diphtheria Toxin. P. G. Heinemann (J. Biol. Chem., 1908, 5, 27—30).—A high potency diphtheria toxin is advantageous in the production of diphtheria antitoxin. Concentration of the former by precipitating with alcohol or salts of heavy metals is accompanied by loss of potency; this, however, is minimised by the use of neutral salts as the precipitating agent. In the present research, ammonium sulphate was used; the salt was subsequently removed by dialysis through heavy parchment. Phenol was then added to the re-dissolved precipitate as a preservative to the extent of 0.3%; more than this precipitates the toxin. The loss of potency is very slight.

W. D. H.

Experimental Glycosuria. II. Glycogenolytic Fibres in the Great Splanchnic Nerve. John J. R. Macleod. III. Influence of Stimulation of the Great Splanchnic Nerve when the Liver is Deprived of its Blood Supply. John J. R. Macleod and H. O. Ruh (Amer. J. Physiol., 1908, 22, 397—409).—Stimulation of the great splanchnic nerve in dogs produces marked hyperglycaemia within half an hour, accompanied by diuresis and glycosuria. If the stimulation is continued for hours, these effects reach a maximum in about two hours and then decline. Liberal administration of oxygen lessens, but does not abolish, the effect; atropine, also, does not prevent the effect. Ligature of the hepatic artery or clamping of the portal vein do not in themselves produce hyperglycaemia. The glycogen which disappears from the liver is greater in amount when the nerve is stimulated when the portal blood is diverted into the inferior vena cava than when the stimulation is omitted. This, however, is not conclusive evidence in favour of glycogenolytic secretory fibres, for the stimulation might produce bloodlessness of the liver by constricting the hepatic artery. If, however, the glycogen still disappears during stimulation of the nerve, when the liver is rendered completely anaemic by ligature of the portal vein and hepatic artery, then the existence of such nerve-fibres is definitely proved. In two out of three experiments, the disappearance was greater during a ten minute period of stimulation than in the preceding ten minutes when no stimulation was employed. If no stimulation is used at all, the rate of disappearance during the second ten minutes is the same as, or less than, that occurring during the first period.

W. D. H.
Calcium Metabolism in Relation to Rickets. **Hans Aron** *(Biochem. Zeitsch., 1908, 12, 28–77).*—A critical and experimental review of calcium metabolism in relation to the aetiology of rickets. The lack of calcium may be due to the small amount in the food, or to its non-absorption, or to its too rapid excretion. The experiments recorded on animals, together with observations on human infants, show the overwhelming importance of the first of these three factors. The effect falls mainly on the skeletal structures, for the amount of calcium may remain normal in other organs. Among the interesting points raised are: (1) the poorness of human milk in calcium, and the suggestion is made that weaning should occur at an earlier date than that usually laid down; and (2) the fact that the milk of mothers of rickety children is poorer in calcium than that of other women in relation to the organic constituents in the milk. Doubtless other factors also step in, especially rapidity of growth in such children.

W. D. H.

**Arsenic and Trypanosomes.** **Martin Jacody** and **Albert Schütze** *(Biochem. Zeitsch., 1908, 12, 193–202).*—Phagocytosis does not appear to be a factor in the defence of the body against trypanosomes, and the beneficial influence of arsenic is not due to its stimulating leucocytic activity, but rather to its direct influence on the parasites.

W. D. H.

**Pharmacological Action of cycloHexane and Some of its Derivatives.** **A. Brissemoret** and **J. Chevalier** *(Compt. rend., 1908, 147, 217–219).*—A comparison of the action of cyclohexane, cyclohexanol, i-quercitol, and inositol on the action of the isolated rabbit’s heart perfused with Locke’s solution. The primary effect (contraction of the heart’s muscle) of all four substances is attributed to their having a common carbon skeleton. With cyclohexane, and especially with cyclohexanol, the toxic effect on the nerves of the heart is most prominent.

G. B.

**[Physiological] Action of Substances of the Saponin Group.** **Leonhard Wacker** *(Biochem. Zeitsch., 1908, 12, 8–14).*—Substances of the saponin group obtained from various plants appear to differ in toxicity; the experiments recorded (on dogs) were performed with a mixture of quillajic acid and sapotoxin. Deleterious effects on the kidney are described. The toxic action on the blood is less if the drug is given by the mouth, and the addition of extracts of the intestinal mucous membrane to solutions outside the body lessens their haemolytic properties; the gastric mucous membrane is even more powerful in the same direction.

W. D. H.

**Absorption of Certain Poisonous Gases by the Respiratory Tract.** **Karl B. Lehmann, Joseph Wiener, Johannes Willke, and Jiří Yamada** *(Arch. Hygiene, 1908, 67, 57–93).*—If the air contains from 0.2 to 0.3% of ammonia, from 80 to 90% of this is absorbed, and absorption is mainly brought about by the nasal and buccal mucous membranes. If the mixture is passed directly into the lungs of an
animal, about 56% of the ammonia is absorbed, but it is not possible to say whether the absorption occurs in the bronchial tubes or in the alveoli.

Hydrogen chloride is absorbed by the nose and trachea to the extent of 60—75%. An animal in this way absorbed 252 milligrams of the gas in an hour, sufficient to produce acid poisoning; injury to the mucous membrane is also readily produced. Sulphur dioxide is absorbed by the same channels to the extent of 35—58%. It is relatively more toxic than hydrogen chloride. Acetic acid vapour is less toxic than hydrogen chloride. It produces hyperæmia and acidity of the mucous membrane, but no hæmorrhage. The amount absorbed varies from 62 to 86%. A few experiments on carbon disulphide are also given; the amount absorbed is about 20—22%. Full analytical details are given throughout; the experiments on animals were supplemented throughout by experiments on man. W. D. H.

Chemistry of Vegetable Physiology and Agriculture.

Action of Heavy Metals on Bacillus Typhorus. Benjamin Moore and James Leonard Hawkes (Bio-Chem. J., 1908, 3, 313—345).—The investigation was undertaken on fresh-water mussels with a view to their purification from the bacillus of typhoid fever. Ferrous sulphate and ferric chloride solutions (1 in 1000) act beneficially on the mussels, and kill all the bacilli in twenty-five hours. Salts of silver, copper, zinc, and lead were found to be useless; they either act detrimentally on the mussels, or do not free them from the bacilli in a reasonable time.

Fermentation of Malic Acid in the Production of Wine. Auguste Rosenstiehl (Compt. rend., 1908, 147, 150—153. Compare Mestrezat, this vol., ii, 723).—Malic acid is transformed into lactic acid and carbon dioxide by Micrococcus malolacticus occurring in the grape; in order to secure proper ripening of the wine, this bacillus should not be allowed to develop rapidly, so that the malic acid disappears slowly.

Fermentation of Calcium Tartrate. Oskar Emmerling (Centr. Bakt. Par., 1908, ii, 21, 317—318).—The experiments were made with a Spirillum found in the waste waters from a tannery. When inoculated into a culture solution containing inorganic and organic food substances and solid calcium tartrate, it was found to decompose the latter salt quantitatively, giving rise to calcium carbonate and carbon dioxide. Thus, in one experiment, 5 grams of the tartrate were originally put into the solution, of which 4.3 were decomposed, giving rise to 2.05 grams of calcium carbonate (theor. = 2.2 grams). Decomposition proceeds more rapidly the greater the surface of liquid exposed to the air and the more frequently the liquid is shaken.
In all fermentations of calcium tartrate studied previously, the reaction has been more complex, and has given rise to several fatty acids.

E. J. R.

Influence of the Sterilisation Temperature of Grape Juice and of the Fermentation Temperature on the "Bouquet" of Wine. Auguste Rosenstiehl (Compt. rend., 1908, 146, 1417—1420).—The best temperature for sterilisation is 50—52°; at 55—60° the bouquet suffers. It is true that at the lower temperature only a partial sterilisation is achieved, but below 26° the surviving yeast cells do not appreciably resume their growth in the first forty-eight hours, so that there is time for the pure culture, with which it is desired to conduct the fermentation, to establish itself. A further reason for conducting the fermentation at a low temperature (20°) is that at a higher temperature the carbon dioxide evolved carries away substances the scent of which makes up the bouquet. The gases given off may be passed into sterile grape juice, to which they communicate the bouquet.

G. B.

De-amidising Ferments of Fungi. Hans Pringsheim (Biochem. Zeitsch., 1908, 12, 15—25).—Various fungi, such as yeast and Aspergillus niger, have the property of liberating ammonia from nitrogenous substances, especially from amino-acids. This is due to enzymatic action. After treatment with acetone and ether, this property is lost. The de-amidised residue is changed into alcohols, with the evolution of carbon dioxide, by an enzyme contained in yeast, which is also killed by acetone and ether. The theoretical bearing on these facts in relation to the growth of fungi is discussed.

W. D. H.

Influence of the Concentration of Sugar Solutions on Respiration [of Seedlings]. A. Maige and G. Nicolas (Compt. rend., 1908, 147, 139—142).—Bean seedlings placed for fifteen to twenty-two hours in sugar solutions of various concentrations (up to 10%) showed increased intensity of respiration, both normal and intramolecular. With all sugars examined, except lactose, the respiration increases progressively with the concentration.

G. B.

Behaviour of Certain Organic Substances in Plants. I. Giacomo L. Ciamician and C. Ravenna (Gazzetta, 1908, 38, i, 682—697).—The glucosides amygdalin, salicin, and arbutin are tolerated by maize and French beans to a much greater extent than the aromatic substances present in the glucosides, namely, benzaldehyde, saligenin, and quinol. The plants into which the latter are introduced die within three days, whilst those treated with the glucosides reach complete maturation. In a period of two months, a single plant can be treated with as much as 3 grams of glucoside without injury.

The glucosides introduced into the plants undergo partial hydrolysis, and are apparently utilised by the plants, since extraction of the latter only yields a fraction of the total glucoside introduced.

T. H. P.
Mechanism of the Distribution of Odoriferous Principles in
Plants. Eugène Charabot and G. Laloue (Compt. rend., 1908, 147,
144—145).—In general, those constituents of an essential oil which
are most soluble in water are most readily transported from the
leaves to the flowers. Menthol is more soluble than menthone, yet in
peppermint plants the flowers contain more menthone than the leaves.
This is, however, the result of oxidation of the menthol after it has
been transported into the flowers, and therefore a secondary effect.

G. B.

Chemical Changes Consequent on the Wounding of
Plants. Rudolf Friedrich (Centr. Bakt. Par., 1908, ii, 21,
330—347).—The author gives a full résumé of previous work on the
subject, dealing especially with (a) the increased evolution of carbon
dioxide, (b) the increased production of protein, in wounded potatoes
and onions. He finds that the former of these phenomena is also
shown by other parts of plants (leaves, fruit, &c.), but not always
the latter; thus potatoes and oak leaves respectively gave the following
results:

<table>
<thead>
<tr>
<th></th>
<th>Total N.</th>
<th>Protein N.</th>
<th>Amide N.</th>
<th>Carbohydrate. Acidity.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Potatoes (tubers), wounded</td>
<td>1'476</td>
<td>1'250</td>
<td>0'123</td>
<td>70'260 24'350</td>
</tr>
<tr>
<td></td>
<td>1'301</td>
<td>0'888</td>
<td>0'167</td>
<td>78'820 21'430</td>
</tr>
<tr>
<td>Oak leaves, wounded</td>
<td>5'171</td>
<td>3'557</td>
<td>1'230</td>
<td>8'191   59'530</td>
</tr>
<tr>
<td></td>
<td>5'392</td>
<td>3'498</td>
<td>1'004</td>
<td>12'436 48'896</td>
</tr>
</tbody>
</table>

The figures refer to percentages on the dry substance.

The fall in carbohydrate is correlated with the increased respiration,
but the increase in acidity is not discussed, since the acids actually
produced were not investigated. It was found that the protein
production in the wounded potato, onion, and pear depended on the
presence of the large amount of carbohydrate; the fruits of Cydonia
japonica and leaves of Oliva Gardneri, which behaved like oak leaves,
contained only small quantities. This observation lends support to
Pfeffer’s view that protein is formed from plants by a reaction
between carbohydrate and amide material.

E. J. R.

Origin of the Colouring Matter of Red Grapes and of Other
Plant Organs. J. Laborde (Compt. rend., 1908, 146, 1411—1413 *).
—By heating the solid parts of young, green grapes with 2% hydro-
chloric acid to 120° for thirty minutes, a red colouring matter is
formed from the tannins. A similar pigment may be formed by
boiling with alkali in the presence of air.

Oxydase in the Latex of Hevea Brasiliensis. David Spence
(Bio-Chem. J., 1908, 3, 351—352).—Four samples of this latex (Para
rubber) gave marked evidence of the presence of an oxidising
enzyme.

W. D. H.

Ripening of Tomatoes (Lycopersicum esculentum). F. M.
Albahary (Compt. rend., 1908, 147, 146—147).—During ripening, a
considerable increase in the amount of organic acids, sugars, starch,
and non-protein nitrogenous substances takes place, whilst proteins
and cellulose diminish.

G. B.

* and Bull. Assoc. chim. Sucr. Dist., 1908, 26, 76—78.
Physiological Action of Dicyanodiamide. Oscar Loew (Chem. Zeit., 1908, 32, 676—677).—Whilst under ordinary conditions calcium cyanamide decomposes entirely into calcium and ammonium carbonates, in alkaline soils there is a possibility of a partial production of dicyanodiamide. According to Ulpiani and Perotti (Abstr., 1907, ii, 295), the latter compound is not poisonous to crops, and may even be employed as a source of nitrogen; Kappen showed that it is very slowly converted into ammonia.

Experiments in which young barley plants (14—16 cm. high) were placed in a 0·5% solution of dicyanodiamide showed an injurious action after two days. In the case of small Lathyrus plants, no injurious action was observed until several days later, owing, perhaps, to evaporation being less. With 0·05—0·1% solutions, only the points of the leaves were affected; solutions of guanidine hydrochloride of the same strength killed barley plants in a few days.

Further experiments with twigs of Tradescantia in 0·1%, and Elodea in 0·2%, solutions of dicyanodiamide showed that no injurious effect was produced in either case, and that Elodea utilised dicyanodiamide as a source of nitrogen. The poisonous effects observed by Immendorff and Wagner were, perhaps, due to some decomposition product. Threads of Spirogyra in 1% solutions of dicyanodiamide remained intact for several days; worms lived for more than four days in 0·5% solutions. Bacteria in broth containing 0·5% were not injured in the least.

As regards the constitution of dicyanodiamide, it is suggested that the imide ring formula (Baumann) best accords with its slightly acid character and with its physiological properties, as compared with dicyanodiamidine and guanidine.

N. H. J. M.

Analytical Chemistry.

Automatic Safety Burette. Gustav Müller and O. Berchem (Chem. Zeit., 1908, 32, 711).—A modification of the apparatus described previously (this vol., ii, 626). The reservoir has been replaced by a tube connected with a large container. The circulation tube is replaced by an overflow chamber fitted with an open conical lid, which is firmly tied to it by means of glass hooks and strong rubber bands. A float, terminating in a cone, serves as a valve, which closes when, after filling the burette, sufficient liquid has entered the overflow chamber.

L. de K.

Detection of Fluorine Compounds in Wines. L. Vandam (Ann. Chim. anal., 1908, 13, 260—262).—A reply to Carles (this vol., ii, 318). The author proves that the amount of fluorine in enological products is too small to interfere with the use of his process (this vol., ii, 63).

L. de K.
Apparatus for the Quantitative Distillation of Ammonia. PHILIP A. KOBER (J. Amer. Chem. Soc., 1908, 30, 1131—1135).—The author has applied Folin's process to the Kjeldahl nitrogen estimations. The fused mass in the Kjeldahl flask, when sufficiently cooled, is mixed with 40—90 c.c. of water (about 4 vols. of water to 1 vol. of sulphuric acid present), and the flask is connected with two cylinders, one containing an amount of aqueous sodium hydroxide more than sufficient to neutralise all the sulphuric acid, and the other, a standard solution of sulphuric acid to absorb the ammonia given off. By applying suction, the alkali is forced into the flask, and the heat developed is sufficient to expel all the ammonia. When all the alkali has been carried over, the cylinder may be disconnected and replaced by an arrangement for supplying ammonia-free air. The suction is continued until the contents of the flask are perfectly cooled down.

L. DE K.

Folin's Method of Estimating Ammonia in Urine. MATTHEW STEEL and WILLIAM J. GIES (J. Biol. Chem., 1908, 5, 71—84).—Certain urines, collected during metabolism experiments with magnesium sulphate, gave discordant results when the ammonia in them was estimated by Folin's method. This is due to the fact that relatively large quantities of ammonio-magnesium phosphate are eliminated under these conditions, some of it being deposited in crystalline form; this deposit is not thoroughly decomposed by sodium carbonate as used in Folin's process, and so a variable amount of ammonia is lost.

W. D. H.

Limitations of the Copper-Zinc Couple Method in Estimating Nitrates. JOHN E. PURVIS and R. M. COURTAULD (Proc. Camb. Phil. Soc., 1908, 14, 441—446).—The authors have examined the accuracy of the copper-zinc couple method of estimating nitrates and nitrites in waters which contain considerable quantities of organic nitrogen compounds, such as soluble peptones, blood-serum, and soluble albumin. From a comparison of the results with those of blank experiments, it is found that the organic nitrogen is to some extent reduced to ammonia under the influence of the couple. Similar results were obtained with a sample of sewage to which known quantities of potassium nitrate were added. It is suggested that the reduction of the organic nitrogen is not merely due to the hydrogen liberated by the couple, but is influenced by the oxygen liberated simultaneously by the electrolytic action.

H. M. D.

The Nitro-Molybdate Method for the Detection of Phosphorus in Tissues. G. G. NASMITH and E. FIDLAR (J. Physiol., 1908, 37, 278—284).—In agreement with Macallum, but contrary to the view of Scott, the cold nitric acid employed does separate inorganic phosphates from nucleins and nucleic acids. Bensley's view is acquiesced in that the reduction of compounds of molybdenum is the cause of the bluish-green colour which appears in microscopic preparations, and that it is not due to the presence of phosphorus at all.

W. D. H.
Estimation of Phosphoric Acid. Norbert von Lorenz (Chem. Zeit., 1908, 32, 707—709).—A defence of the author's method (direct weighing as ammonium phosphomolybdate), which is applicable in all cases, whereas the citrate process gives but indifferent results.

L. de K.

Microchemical Analysis. III. Arsenic, Antimony, Tin. Nicolaas Schoorl (Zeitsch. anal. Chem., 1908, 47, 367—389. Compare this vol., ii, 432).—The process is based on the characteristic microscopical appearance of arsenious acid, ammonium calcium arsenate, ammonium magnesium arsenate, and arsenic iodide. Antimony may be isolated as caesium antimony chloride or, preferably, iodide, or as sodium antimonate, whilst tin yields characteristic compounds with caesium and rubidium chlorides, all of which are readily detected microscopically.

Tin and antimony are conveniently separated from arsenic by heating the mixed sulphides obtained in the ordinary course of analysis with 25% hydrochloric acid, which leaves the arsenic practically undissolved. A portion of the filtrate is then tested for tin with rubidium chloride, and another portion for antimony with caesium chloride and potassium iodide. The arsenic is oxidised with nitrohydrochloric acid, and then converted into the magnesium compound.

L. de K.

Separation of Lithium Chloride from the other Alkali Chlorides and Barium Chloride. Louis Kahlenberg and Francis C. Krauskopf (J. Amer. Chem. Soc., 1908, 30, 1104—1115).—The solution of the mixed chlorides is evaporated just to dryness, and the residue, which should not exceed 2 grams, is boiled for a few minutes with 25 c.c. of pyridine; any large particles are crushed with a stirring rod. The clear liquid is decanted through a small filter, and the insoluble matter washed twice with a little hot pyridine. It is then dissolved in a little water, evaporated to bare dryness, and again extracted with hot pyridine. The pyridine filtrates, which contain all the lithium chloride, are mixed, the bulk of the pyridine is recovered by distillation, and the lithium chloride is converted into sulphate by evaporation with sulphuric acid and weighed as such.

L. de K.

Assay of Telluride Ores. George Borrowman (J. Amer. Chem. Soc., 1908, 30, 1023—1027).—The irregularities in the assay of high-grade auriferous tellurides are due to lack of homogeneity of the sample, and not, as has been suggested, to the tellurium. In some cases, however, it is advisable to remove the tellurium with nitric acid. Any silver is then precipitated as chloride, and added to the insoluble residue, which is then assayed as usual for gold and silver. The most favourable temperature is about 1200°.

L. de K.

The red lead may be dissolved in dilute nitric acid, and separated from insoluble impurities by the use of such reducing agents as sucrose, oxalic acid, lactic acid, methyl alcohol, formaldehyde, glycerol, phenylhydrazine, salts of hydroxylamine, but best of all by hydrogen peroxide.

When small quantities only are available, Bunsen's process (distillation with hydrochloric acid and estimation of the chlorine liberated) may be used, but in works, Topf's process (titration of iodine liberated from potassium iodide with sodium thiosulphate) should be used, as this allows the use of 5 grams of the sample.  

L. de K.

Solubilities of the Oxalates of the Rare Earths. I. Solubility of the Oxalates of Lanthanum, Cerium, and Samarium in dilute Sulphuric and Oxalic Acids or their Mixtures. Otto Hauser and Fritz Wirth (Zeitsch. anal. Chem., 1908, 47, 389—400).—Tables showing the solubility of the oxalates of the cerium group in dilute sulphuric and oxalic acids, and in a mixture of the two; the strength of the acids varies from 0·05\(N\) to 4·3\(N\).

As a result of this investigation, the following process is recommended. The rare earths are separated from accompanying alkaline earths by precipitation with ammonium chloride and pure ammonia. The washed precipitate is dissolved in hydrochloric acid, and, after expelling the excess by evaporation, the residue is dissolved in about 60 parts of \(N/4\)—\(N/2\) sulphuric or hydrochloric acid. A saturated solution of oxalic acid is then added in such quantity that the solution will contain about 3\% of that acid. If lanthanum is present in large excess, ammonium oxalate should be used. In presence of more acid, the process becomes quite inaccurate for lanthanum, and less accurate for cerium.  

L. de K.

Influence of Fine Grinding on the Water and Ferrous Iron Content of Minerals and Rocks. William F. Hillebrand (J. Amer. Chem. Soc., 1908, 30, 1120—1131).—A series of tabulated experiments on the influence of fine grinding on minerals containing ferrous iron and on the iron and water content. In order to avoid oxidation, it is recommended that the grinding should be effected under alcohol, or, better still, the coarse powder should be treated directly with hydrofluoric acid and the solution titrated for ferrous iron; any undissolved matter is then finely ground under water, and again treated with hydrofluoric and sulphuric acids (for details, compare Bull. 305, U. S. Geol. Survey, 142).  

L. de K.

Volumetric Estimation of Iron and Chromium by means of Titanous Chloride. S. B. Jatar (J. Soc. Chem. Ind., 1908, 27, 673—674).—The principles involved in the method are: (1) hydrogen peroxide oxidises chromium salts in alkaline solutions to chromates, these becoming dichromates on acidifying the solutions; (2) hydrogen peroxide reduces dichromates to chromates in acid solutions, ferric salts being unchanged; (3) on titrating a mixture of a dichromate and a ferric salt, for all practical purposes the dichromate is reduced first,
the colour change marking the reduction and the ferric salt being left in solution. Of these, the first one is involved in bringing the iron and chromium in an ore into solution; on the second and third, the following process depends. A weighed quantity of about 0·5 gram of the finely-powdered ore is fused with a mixture of sodium hydroxide and sodium peroxide, more of the latter being added subsequently. After cooling, the fused mass is extracted with water, the solution is boiled to remove all traces of hydrogen peroxide, then acidified with sulphuric acid, and again boiled and diluted to a volume of 500 c.c. Fifty c.c. of the solution are titrated with standardised titanous chloride solution until a clear violet coloration is obtained, showing that all the dichromate is reduced; a few more drops of titanous chloride are added to make sure that only the ferric salt remains in solution, then a few drops of thiocyanate solution are added as indicator, and the solution is titrated until the colour disappears. The volume of titanous chloride solution used represents the dichromate and iron together. A second 50 c.c. of the solution are treated with hydrogen peroxide to reduce the dichromate, and the mixture is boiled to expel the excess of hydrogen peroxide. When cold, the solution is titrated with titanous chloride solution, a few drops of thiocyanate solution being added as an indicator. In this titration, the volume of titanous chloride used represents the amount of iron only. A sensitive indicator may be prepared by adding a few drops of potassium thiocyanate solution to a dilute ferrous sulphate solution.

W. P. S.

Estimation of Nickel and Chromium in Steel. Edward D. Campbell and Walter Arthur (J. Amer. Chem. Soc., 1908, 30, 1116—1120).—A modification of Moore's process. One gram of the sample is converted into sulphate by evaporating with nitric acid and sulphuric acid, and to the solution, measuring about 70 c.c., 13 grams of sodium pyrophosphate dissolved in 70 c.c. of hot water are added. This is preferable to the citric acid usually employed. The precipitate is dissolved by cautious addition of ammonia, and warming towards the end.

Five c.c. of 0·05% silver nitrate and then 5 c.c. of 2% potassium iodide are added, and standardised potassium cyanide is run in until a clear liquid has been obtained. If copper is present, it must be remembered that 1 part of this counts for 4 part of nickel. Copper, however, may be left undissolved by avoiding the use of nitric acid. If chromium is also present, it must be rendered harmless by oxidation with potassium permanganate before adding the pyrophosphate. If chromium only has to be estimated, the chromic acid thus formed is titrated in the usual way with ferrous ammonium sulphate and permanganate.

L. de K.

Separation of Tungsten from Chromium. Estimation of Tungsten in Steel containing Chromium. Georg von Knorre (Zeitsch. anal. Chem., 1908, 47, 337—366).—1·5—6 Grams of the sample are dissolved in a small quantity of dilute hydrochloric acid. When no further action takes place on boiling, the excess of acid is at
once neutralised with sodium hydroxide, and, when cold, 8—10 c.c. of N/10 sulphuric acid are added, and then, without previous filtration, 30—60 c.c. of benzidine reagent (20 grams of benzidine and 25 c.c. of concentrated hydrochloric acid per litre). The precipitate, which contains all the tungsten, also more or less chromium, is washed with the diluted reagent and burnt in a platinum crucible. The ash is then fused with sodium carbonate, and the mass extracted with water. The filtrate is acidified with hydrochloric acid, using methyl-orange as indicator, and then boiled for some time to convert the tungsten into metatungstic acid. When cold, the chromic acid is reduced by a solution of sulphur dioxide, and the tungsten precipitated with excess of the benzidine reagent. Addition of sulphuric acid is, as a rule, unnecessary, as enough is formed owing to the oxidation of the sulphur dioxide. On ignition, pure tungsten trioxide is obtained.

L. de K.

Volumetric Estimation of Titanium. Gino Gallo (Gazzetta, 1908, 38, i, 658—659. Compare Abstr., 1907, ii, 402, and Knecht and Hibbert, Abstr., 1903, ii, 509).—Titanium is usually accompanied by iron, so that the method given by Newton (this vol., ii, 325) for the volumetric estimation of titanium is inapplicable in practice.

T. H. P.

Purity and Volatility of Precipitated Antimony Sulphide. Lewis A. Youtz (J. Amer. Chem. Soc., 1908, 30, 975—979).—Antimony sulphide precipitated from a solution containing free hydrochloric acid is never pure, but is always contaminated with more or less antimony oxychloride, which cannot be removed even by redissolving the precipitate in ammonium sulphide and reprecipitating with acetic acid. In practice, this admixture does not interfere with the accuracy of the analysis if care is taken to heat the precipitate in an atmosphere of carbon dioxide at 250° only just long enough to transform it into the black sulphide; a prolonged heating causes volatilisation of the antimony oxychloride, and consequent loss.

Antimony sulphide precipitated from a solution free from chlorides does not suffer loss on prolonged heating at 250° in a current of carbon dioxide.

L. de K.

Electrolytic Estimation of Bismuth. J. Pezet (Zeitsch. anal. Chem., 1908, 47, 401).—0.04—0.08 Gram of a bismuth salt is heated with 4—5 c.c. of water and 3 c.c. of sulphuric acid, and, when all is dissolved, the solution is diluted to 140 c.c. and submitted to electrolysis, using a rotating anode. Conditions: 2 volts; 0.002 to 0.01 ampere; temperature, 50°; time, eighteen to twenty hours. When the solution is quite free from bismuth, 0.08—0.15 gram of accurately-weighed cadmium sulphate dissolved in 10 c.c. of water is added, and the electrolysis is continued now under the following conditions: 2.5—3.5 volts; 0.2—0.3 ampere; time, eight hours.

The cadmium thoroughly protects the bismuth from oxidation, and renders it more adhesive.

L. de K.
Simple Form of Apparatus for Observing the Rate of Absorption of Oxygen by Polluted Waters and by other Fermenting Liquids. WALTER E. ADENEY (Sci. Proc. Roy. Dubl. Soc., 1908, 11, 280—287).—It has been shown (Abstr., 1896, ii, 322; 1898, ii, 86; 1902, ii, 221) that the determination of the extent and rate of absorption of oxygen is of fundamental importance in the examination of polluted waters. A simple apparatus for carrying out these determinations has now been devised, and is figured in the accompanying diagram. Flask $B$ is charged with the polluted water and $A$ with distilled water. The taps $a_2$ and $b_2$ being closed, absorption takes place in $B$, but not in $A$, which acts therefore as a standard pressure gauge. The difference of pressure read off on the graduated tube $a$, in which the distilled water rises when $b_1$ is opened, shows the amount of absorption in $B$. The original should be consulted for details as to the size of the apparatus, the method of use, and the manner of calculating the results.

Detection of Free Acids in Organic Liquids. FERNAND REPITON (Ann. Chim. anal., 1908, 13, 269—270).—Five c.c. of Fehling's solution are boiled in a test-tube, and, if no change takes place, a few drops of the solution to be tested for acidity are added, when a precipitation of copper oxide takes place. One drop of an $N/10$ acid solution will give the test.

Physico-chemical Analysis of Wines. PAUL DUTOIT and MARCEL DUBOUX (Compt. rend., 1908, 147, 134—137).—A strong solution of baryta is added in small portions to the wine, the conductivity of which is measured after each addition. At first the conductivity falls, and a sharp minimum indicates the point at which all the sulphates have been precipitated. It then rises to a maximum, corresponding with neutrality to litmus. On further addition of baryta, a gelatinous precipitate occurs, and the curve of conductivity shows a shallow dip, the length of which is a measure of the amount of tannins present. After this, the conductivity rises in a straight line. In one operation, three constituents of the wine are thus determined, the sulphates and acids with great accuracy.
Origin and Variations of Sulphates in Beer. Interpretation of Analytical Results. Achille Muntz and J. Auguste Trillat (Ann. Chim. anal., 1908, 13, 253—260).—An investigation to ascertain whether the presence of more than 2 grams of potassium sulphate per litre in beer should be called adulteration. The authors point out that even more than 2 grams may be fully accounted for by the sulphate derived from the water (Burton water, for instance) and the other materials used in the brewing process. The potassium is derived mainly from the malt, and is often present in sufficient quantity to cover the sulphate fully; the authors, however, doubt whether even then it is really permissible to calculate and report all the SO₃ found as potassium sulphate.

A further quantity of sulphate is due to the sulphuring of the hops or from the use of sulphites; a special test should be made to detect the latter.

L. de K.

Detection of Thiocyanic Acid by means of Mercurous Chloride. Egidio Pollacci (Chem. Zentr., 1908, i, 1576; from Arch. Farmacol. sperim., 7, 94—96).—To detect thiocyanic acid in saliva, 12—15 c.c. are warmed with 40—42 c.c. of absolute alcohol, the filtrate is concentrated to 6—7 c.c., and the residue again filtered. On adding mercurous chloride, this will be reduced in the cold to metallic mercury, which reaction is characteristic for thiocyanic acid. The process may be applied also to solid animal matter.

L. de K.

Estimation of Citral in Lemon-grass Oil. Armand Bloch (Chem. Zentr., 1908, i, 1500; from Bull. Sci. Pharmacol., 1908, 15, 72—77).—Ten c.c. of the sample are introduced into a 100 c.c. flask, the neck of which holds fully 10 c.c., and is graduated to 0·1 c.c. Twenty c.c. of a recently-prepared 30% sodium hydrogen sulphite solution are added, and the mass shaken until solidified. After fifteen minutes, the flask is suspended in a water-bath at 85°, and, when with constant shaking the mass has liquefied, the flask is three-fourths filled with the sulphite solution. After four to six minutes, a layer of oil will have formed, and more of the reagent is then added until the flask is filled up to the neck. After eight minutes, more is added so as to fill the graduated neck, and, after keeping the flask in the water-bath for another ten minutes, it is taken out and allowed to cool. The volume of unabsorbed oil is then read off.

L. de K.

Titration of Chloral Hydrate. Jules Garnier (Chem. Zentr., 1908, i, 1492; from Bull. Sci. Pharmacol., 1908, 15, 77—82).—In order to prevent a secondary reaction from taking place between the chloroform formed and the alkali, the test should be carried out as follows: 0·1655 gram of the sample is dissolved in 10 c.c. of water, and 12·5 c.c. of N/10 potassium hydroxide are added. The temperature should not exceed 15°, and, after fifteen to twenty minutes, the excess of alkali is titrated with N/10 sulphuric acid, with phenolphthalein as indicator. Another experiment should then be made, using only the slightest excess of alkali.

L. de K.
Estimation of Acetone in Urine. T. Stuart Hart (J. Biol. Chem., 1908, 4, 477—482).—The acetoacetic acid in the urine is first converted into acetone by heating at 100°; the acetone is then drawn by a current of air into the absorbing cylinder, as in Folin's method (Abstr., 1907, ii, 588). The values for total acetone plus acetoacetic acid closely approximate to those obtained by the more lengthy Messinger-Huppert procedure. W. D. H.

The Estimation of Indole in Fæces by Herter and Foster's Method. E. Gorter and W. C. de Graaff (Pharm. Weekblad, 1908, 45, 842—845).—Fæces are distilled with steam in presence of potassium hydroxide, and the distillate again distilled with steam after acidification with sulphuric acid. The indole is estimated in the second distillate by Herter and Foster's colorimetric method, using a standard solution prepared from pure indole. A. J. W.

Direct Application of Kerner's and of Liebig-Hesse's Process to Quinine Disulphate. Pietro Bigielli (Chem. Zentr., 1908, i, 1499—1500; from Mon. Sci., 1908, [iv], 22, 185—187).—The conversion of the quinine disulphate into the normal salt is effected in the cold by lead carbonate (also compare Abstr., 1907, ii, 317). L. de K.

Estimation of Casein: Determination of its Molecular Weight. Georg Th. Matthaiopoulos (Zeitsch. anal. Chem., 1908, 47, 492—501).—The process is based on the fact that casein forms a definite compound with sodium hydroxide when using phenolphthalein as indicator; in this compound, the casein seems to have a molecular weight of 1131.5, practically agreeing with the molecular weight 1135 attributed to it by Laqueur and Sackur (Abstr., 1903, i, 300).

The analysis is conducted as follows: In two separate beakers are placed 80 c.c. of water and 20 c.c. of milk, N/25 sulphuric acid is added to the milk until the casein appears to be completely precipitated, and the same amount is then added to the second beaker; as a rule, some 21 c.c. are required. To the contents of the control beaker is now added 1 c.c. of 1% alcoholic phenolphthalein, and the whole titrated with N/10 sodium hydroxide. The contents of the other beaker are filtered until 100 c.c. of a clear filtrate have been obtained. This is then also titrated with N/10 soda, and, after making an allowance for the dilution caused by the acid added, the difference in the titrations represents the alkali absorbed by the casein; 1 c.c. of N/10 alkali = 0.11315 gram of casein. L. de K.

Pettenkoffer's Reaction. Gabriel Guérin (J. Pharm. Chim., 1908, [vi], 28, 54—54).—The Pettenkoffer reaction for biliary acids is due to the formation of a trace of furfuraldehyde from the sugar added, and, in fact, a trace of this aldehyde may be substituted for the sugar.

The author now states that if a larger quantity of furfuraldehyde is employed, the colour generated is not purple, but blue. The test may be applied as follows: A small quantity of the biliary salts is dissolved in 1—2 c.c. of alcohol, 5—6 drops of a saturated aqueous solution of
furfuraldehyde are added, and then slowly an equal volume of sulphuric acid, when the blue colour will be developed at once. If an aqueous solution has to be tested, twice the quantity of furfuraldehyde should be employed.

The blue coloration is due entirely to the formation of cholic acid.

L. de K.

Colour Test for Alypine and various other Local Anæsthetics. P. Lemaire (Ann. Chim. anal., 1908, 13, 301—303).—The author has successfully applied the sulphonation test for benzoic acid to some local anæsthetics.

Two c.c. of pure sulphuric acid are placed in a test-tube, 0·05 gram of the substance is added, and the mixture heated until white fumes appear. 0·4 Gram of potassium nitrate in fine crystals is then added in small portions, and, when cold, the liquid is poured carefully into a beaker containing 25 c.c. of dilute ammonia (1:1). On adding a drop of ammonium hydrogen sulphide, a reddish-brown coloration appears. The test is successful with alypine (benzoyletreamethyldiaminopentanol hydrochloride), stovaine (benzoyldimethylaminopentanol hydrochloride), cocaine hydrochloride, tropacocaine hydrochloride, a-eucaine hydrochloride, and β-eucaine hydrochloride.

With other substances of this class, the test is indistinct, owing to secondary reactions.

L. de K.
General and Physical Chemistry.

Refractive and Dispersion of Helium. Kurt Herrmann (Ber. deut. physikal. Ges., 1908, 6, 476—482. Compare this vol., ii, 333).—Measurements of the refraction of air, hydrogen, and helium have been made for the cadmium line \( \lambda = 0.6438 \mu \). The values of the refractive index are for air 1.0002930, hydrogen 1.0001380, helium 1.00003406, at 0° and 760 mm. The values of \( v \) in the expression for the relative dispersion \( 1/v = (n_x - n_v)/(n_D - 1) \), where \( n_x \), \( n_v \), and \( n_D \) are the refractive indices for the lines \( F \), \( C \), and \( D \), are for air 98.0, hydrogen 65.9, and helium 39.9.

H. M. D.

Index of Refraction of Mixtures of Alcohols and Water.

II. Antony G. Doroschewsky and S. V. Dvorschantschik (J. Russ. Phys. Chem. Soc., 1908, 40, 908—931. Compare this vol., ii, 241).—The curves connecting the index of refraction of aqueous alcohol with the proportion of alcohol present for thallium, lithium, and sodium lights are of the same type, all exhibiting maxima at the same concentration; the curves become less convex as the wave-length is increased. Rise of temperature also results in a flattening of the curve, and in a displacement of the position of the maximum towards the water axis.

When water is added to isopropyl alcohol, a well-defined maximum refrangibility, corresponding with 93—94% of the alcohol, is observed. With normal propyl alcohol, a less clearly marked maximum exists at about 97%. With butyl and isobutyl alcohols, addition of water causes lowering of the index of refraction, no maximum being observed. The rate of change of the index of refraction with temperature, \( dn/dt \), also varies regularly, exhibiting a maximum in the region of the maximum index of refraction. In general, the magnitude of \( dn/dt \) for propyl, isopropyl, butyl, and isobutyl alcohols varies little, but diminishes slightly as the molecular weight of the alcohol increases, and is greater for the isoalcohols than for the normal ones.

The value of \( a \) in Pulfrich’s formula (Zeitsch. physikal. Chem., 1889, 4, 561) \( (n - n_v)/n = a(D - D_v)/D \) has been calculated for mixtures of ethyl, propyl, and isopropyl alcohols with water, and is found to be a constant independent of the temperature and of the wave-length of the light used. For ethyl alcohol, the mean value of \( a \) is 0.075, for propyl alcohol, 0.92, and for isopropyl alcohol, 0.95. Knowing the value of \( a \), the indices of refraction of mixtures of alcohol and water, and the specific gravities and indices of refraction of absolute alcohol and water, the compression of the aqueous alcoholic mixtures can be calculated; results obtained in this way for various mixtures of ethyl alcohol and water at 15°, 20°, and 30° agree closely with the experimental numbers. Calculation of the concentration of mixtures of alcohol and water by means of Gladstone’s formula, \( (n - 1)/d = \text{const.} \),

VOL. XCIV. ii.

54
yields accurate results, which are also given by Pulfrich's (loc. cit.)
modification of Gladstone's formula.

The expansion of liquids by heat is expressed with great accuracy
by the equation \( v_t = v_0/(1 - kt) \) (compare Mendeléeff, J. Russ. Phys.
Chem. Soc., 1884, 16, 1). The authors find that a similar equation,
\( n_t = n_0/(1 + kt) \), gives accurately the relation between the index of
refraction of a liquid and the temperature; \( k \) is termed the modulus
of the index of refraction.

T. H. P.

New Law of Series Spectra. W. Ritz (Physikal. Zeitsch., 1908,
9, 521—529).—A formula is given by means of which new series of
spectral lines can be deduced from known series. The newly-discovered
series of lines in the spectra of the alkali metals are accurately
represented by means of the formula, and it is also shown that the
series of lines in the spectra of helium, copper, and the alkaline earth
metals are in agreement with it.

H. M. D.

Spectrum of the Lighter Constituents of Air. Herbert E. Watson
(Proc. Roy. Soc., 1908, 81, A, 181—194).—The lighter portions of
air were separated by fractional distillation by Coates (Abstr., 1907,
ii, 257), and the portion not absorbed by charcoal at \(-190^\circ\) was
further fractionated. One fraction pumped off charcoal at \(-205^\circ\), and
a second fraction at \(-190^\circ\), have now been examined spectroscopically
by the author. The spectra of the first order, and, for all lines of
wave-length less than 4100, of the second order as well, obtained with
a Rowland grating, were photographed. A very long exposure was
given in order that faint lines might not be overlooked.

The wave-lengths obtained, along with those of Liveing and Dewar
(Abstr., 1901, ii, 213) and Baly (Abstr., 1904, ii, 3) for comparison,
are given in tabular form. After allowing for the lines ordinarily
ascribed to helium and neon (and also to traces of argon and hydrogen),
a considerable number of lines remain unaccounted for. These lines,
however, do not appear to show more than accidental coincidences
with any of the chief nebular or coronal lines, or with any of the lines
of the spectrum of the solar chromosphere. It seems probable, there-
fore, that the majority are really neon lines which were not observed
previously owing to insufficient exposure, and there is no evidence that
the fractions contain gases other than those already mentioned.

G. S.

Spectrum of Radium Emanation. Alexander T. Cameron and
Sir William Ramsay (Proc. Roy. Soc., 1908, 81, A, 210—213).—In a
previous paper (Abstr., 1904, ii, 529), Ramsay and Collie gave
measurements of the spectrum of radium emanation obtained with
a direct-vision spectroscope. The spectrum in question has now been
photographed. Three successive photographs were taken, but only the
first showed the spectrum of the emanation alone, as the effect of the
discharge is to drive the emanation towards the negative electrode,
where it is largely absorbed, and the tube soon shows only the
hydrogen spectrum.
Much better results were obtained with copper electrodes in place of the aluminium electrodes first used. The former electrodes appear not to contain hydrogen, and absorb the emanation much more slowly than aluminium does.

The wave-lengths and intensities of the lines ascribed to the emanation are given in the paper (compare Rutherford and Royds, following abstract).

**Spectrum of Radium Emanation.** Ernest Rutherford and T. Royds (*Phil. Mag.*, 1908, [vi], 16, 313—317. Compare Cameron and Ramsay, preceding abstract).—The spectrum of radium emanation purified as well as possible from permanent gases and carbon dioxide was found to consist of entirely characteristic lines. The authors have mapped a spectrum of seventy-four lines between 3612.2 \( \lambda \) and 6079 \( \lambda \), thirty-nine lines being observed visually, and sixty-three photographed. None of these lines has been identified in any stellar spectrum.

The colour of the discharge is bluish, the spectrum being characterised by groups of brilliant green and violet lines.

During the passage of the discharge, the emanation lines grow gradually weaker, and the emanation itself appears to be driven into the walls of the tube, whence it is removed with difficulty by strongly heating the glass. After three days, the glass is much blackened, and the principal lines of helium appear in the spectrum.

**Quantitative Indications Furnished by Dissociation Spectra: Silver.** Antoine de Gramont (*Compt. rend.*, 1908, 147, 307—309. Compare Abstr., 1907, ii, 728; this vol., ii, 645).—The following series of argentiferous materials have been examined spectroscopically, employing the simple or oscillating condensed spark: (1) galena; (2) commercial lead; (3) alloys of lead and silver; (4) alloys of tin and silver, all of known composition. Spectra of the four classes have been photographed on the same plate, and to render the quantitative indications comparable, six spectra of each class, representing six different concentrations of silver, have been recorded by vertical movement of the plate. It is found that the number and intensity of the lines for silver have a direct and constant relation to the concentration of the metal in the sample. A table is given showing the lines which disappear at different concentrations of silver from 1% to 0.0001%.

It is necessary to guard against certain foreign lines which coincide with those of silver, and also against the halo occasioned by bright lines of lead or tin.

The air supply of a Bunsen flame is charged with a spray produced by electrolysis of a suitable solution.

The laws of electric dichroism are shown, theoretically and experimentally, to be similar to those established by Meslin (loc. cit.) for magnetic dichroism. But whilst the sign of electric dichroism is independent of the relative value of the dielectric constants of the media, that of magnetic dichroism can be altered by modifying the relative value of the magnetic constants of the solid and surrounding liquid. The dichroism is proportional to the length of liquid traversed by the light and to the concentration of the liquid, and increases with the intensity of the field to a limiting value.

A mixture of liquids placed in a uniform electric field exhibits marked birefringence, provided that the suspended particles are sufficiently minute.

The field due to gravity is also capable of producing the phenomena of dichroism and even of birefringence. The action of any uniform field is hence manifested in an orientation of the particles of mixed active liquids, which then exhibit the phenomena of dichroism and birefringence; the laws of these phenomena are the same whatever the nature of the field, provided that account is taken of the change of sign due to diamagnetism. If the particles in suspension have a greater magnitude than about 0·3 mm., dichroism alone is observed, and is due to the reflection of light by the crystalline surfaces. If the particles are smaller and uniform in size, dichroism is still the principal phenomenon observed, but birefringence also appears, and the modifications due to diffraction come into play. As the dimensions of the particles diminish, dichroism becomes rarer, and birefringence plays a more important rôle, whilst, when they are infinitely small, as in colloidal solutions, the phenomena of reflection and refraction are no longer produced and the liquids are only birefringent. T. H. P.

Electrochemistry of Light. III. Halogen Carriers. Wilder D. Bancroft (J. Physical Chem., 1908, 12, 417–447. Compare this vol., ii, 448, 549).—The facts and theories relating to the action of carriers in the chlorination and bromination of hydrocarbons are discussed, and a new theory is put forward which resembles in some respects that advanced by Bruner (this vol., i, 146).

The chief conclusions at which the author arrives are that the action of halogen carriers is not due to the intermediate formation of additive compounds, and that under suitable conditions the carriers react with the hydrocarbons even in the absence of free halogen.

To account for the observed facts of substitution in the side-chain and in the nucleus, it is supposed that the halogens and the carriers give rise to ions, and that substitution takes place in the nucleus when the negative ions are present in excess and in the side-chain when the positive ions predominate. By means of this theory, the catalytic action of ferric, stannic, and aluminium chlorides, as well as of iodine
monochloride, phosphorus pentachloride, water, and sunlight, can be accounted for. The facts relating to the velocity of the reactions when certain of these carriers are employed can also be explained.

H. M. D.

Photographic Action of Metals and Hydrogen Peroxide (So-called Metallic Radiation). Sem Sæland (Ann. Physik, 1908, [iv], 26, 899—917. Compare Russell, Abstr., 1898, ii, 287; 1899, ii, 720).—An investigation has been made of the conditions under which photographic action is produced by certain metals and by solutions of hydrogen peroxide, and from the results the author concludes that the action of the metals is due to chemical changes and not to the emission of any special type of radiation.

The activity of the metals, measured immediately after polishing the surface, increases with the electropositive character, and the greater the activity of the freshly-polished metal the more rapidly does this activity diminish with time. When the metal is kept in a vacuum, this diminution in the activity does not take place. The photographic activity is also unaltered after the metals have been heated, and exposure to an electrical field has no influence on the photographic effect. The darkening of the plates is greatly increased if the plates are left undeveloped for some time, or if before developing they are gently heated.

In a vacuum containing phosphoric oxide, the photographic action does not take place; conditions under which hydrogen peroxide can be formed appear to be essential. Experiments are also described which indicate that the action does not spread from the active metals in a rectilinear manner, but that, on the other hand, the distribution is such as would be expected if gaseous diffusion were taking place. The photographic action is not observed when certain metals, such as copper, or alloys, like brass, are interposed as diaphragms between the active metals and the photographic plate. It is also inhibited if very thin, non-porous sheets of metals are interposed, or if a sufficiently rapid current of air is passed between the photographic plate and the active metal.

The observations indicate the identity of the action of metals and of hydrogen peroxide solutions. The metals therefore exhibit photographic activity in consequence of the formation of hydrogen peroxide, and are only active when the conditions are such that hydrogen peroxide can be produced.

H. M. D.

Relation of Absorption and Sensitiveness in Photographic Preparations. Erich Lehmann (Zeitsch. physikal. Chem., 1908, 64, 89—119).—The question as to the influence of wave-length on the relation of optical absorption to photochemical extinction has not hitherto received a definite answer. The author shows that in the case of silver iodide a solution of the problem is possible. For silver iodide either by itself or in collodion, the maximum of absorption and the maximum of sensitiveness are coincident. In a gelatin emulsion of silver iodide, however, the maximum of sensitiveness is displaced.
16.65 µµ relatively to the absorption maximum. This may be due to the formation of an organic silver salt.

It is exceedingly probable that similar results would be obtained with silver chloride and bromide if these substances could be subjected to direct observation.

J. C. P.

Photochemical Oxidation of Hydrogen Iodide by Oxygen. JOH. PLOTNIKOFF (Zeitsch. physikal. Chem., 1908, 64, 215—228. Compare Abstr., 1907, ii, 212).—The rate of decrease of the oxygen concentration is now found to be proportional to the 2/3 power of the acid concentration both in the light and in the dark. The fact that in the earlier work different values were found for the exponent of the hydrochloric acid concentration in the light and in the dark was probably due to some catalytic agent, and it is now shown that the presence of copper sulphate is sufficient to cause such a difference.

For the reaction in the dark, the value of \( K_{T+10}/K_T \) is now found to be 2.07; for the reaction in the light the value is 1.38.

The author's further experiments show that the photochemical oxidation of hydrogen iodide by oxygen is the sum of two independent changes: (1) the reaction in the dark; (2) the reaction in the light. Hence the velocity may be represented by the formula:

\[
\frac{d(O_2)}{dt} = [K_a \cdot 10a^2 + K_r \cdot 1.10^{37}](HCl)^{2/3}(KI)^{1/3}(O_2).
\]

J. C. P.

Method of Carbon Dioxide Assimilation. EMIL BAUR (Zeitsch. physikal. Chem., 1908, 63, 683—710).—A solution of potassium ferric oxalate in diffused daylight evolves carbon dioxide, but the evolution of gas ceases before all the ferric salt is decomposed. When a solution of potassium ferrous oxalate is kept in an atmosphere of carbon dioxide, the gas is gradually absorbed, and ferric salt is produced. These observations may be summed up in the equation:

\[
\text{Fe(C}_2\text{O}_4\text{)}_3\text{K}_3 \rightleftharpoons \text{Fe(C}_2\text{O}_4\text{)}_2\text{K}_2 + \frac{1}{2}\text{C}_2\text{O}_4\text{K}_2 + \text{CO}_3.
\]

The reversibility of this reaction has led the author to consider the suggestion, that in the original production of organic compounds the reduction of carbon dioxide to oxalic acid was the first stage. In order to make the energy of light available for this reduction, the system ferrous oxalate + ferric oxalate + carbon dioxide must be combined with a system in which oxygen is developed under the influence of light. This latter result is attained, for instance, when silver chloride immersed in water is exposed to light, and the author shows how in a vessel provided with a septum of photochloride and a semipermeable membrane it would be possible, theoretically at least, to effect the conversion of carbon dioxide and water into oxalic acid and oxygen. In endeavouring to find other systems which, like silver chloride in water, would evolve oxygen on exposure to light, the author has studied the way in which the potentials of iron, mercury, uranium, and cerium salts are affected by light. The P.D. at a platinum electrode immersed in a solution containing both uranoxy and uranyl salts is actually less positive when exposed to sunlight than when kept in the dark. The displacement of potential is considerable, and takes place more or less rapidly according to the
nature of the salts employed. The results obtained with iron, mercury, and cerium salts were less noteworthy.

The term "light content" ("Lichtinhalt") is proposed for the quantity of energy which is absorbed by a light-sensitive substance, and which goes to change its chemical potential. The value of this "light content" is deduced from the \(E.M.F.\) of photoelectric cells and their temperature- coefficients.

J. C. P.

Distribution of the Radiation from Radioactive Substances. HEINRICH W. SCHMIDT (Physikal. Zeitsch., 1908, \(\varnothing\), 537—541).—To explain the irregular distribution of the radiation from substances containing uranium, which Greinacher (this vol., ii, 551) found on examination of photographic plates which had been placed in contact with these substances cut into sections of well-defined geometrical forms, it is not necessary to attribute the action to secondary rays. The phenomenon can be referred to the action of the \(\beta\)-rays if it is assumed that the emitted rays follow the cosine law of Lambert. Conversely, the experimental observations indicate the validity of this law in the case of corpuscular radiation.

H. M. D.

Experiments with Radium Emanation. Volume of the Emanation. ERNEST RUTHERFORD (Phil. Mag., 1908, \(16\), 300—312).—The amount of emanation in equilibrium with one gram of radium is \(q/\lambda\), where \(q\) is the rate of production per second and \(\lambda\) is the radioactive constant of the emanation. The value of \(\lambda\) is about \(1/46\,800\).

Assuming that one atom of radium emits one \(\alpha\)-particle and then becomes one atom of emanation, and knowing the number of \(\alpha\)-particles emitted per second and the charge on each (Rutherford and Geiger, this vol., ii, 794), the author calculates the volume of the emanation to be 0.57 cub. mm. per gram of radium. Ramsay and Cameron, however (Trans., 1907, \(91\), 1266), obtained 7.07 cub. mm. of emanation from one gram of radium. The author finds that probably 80% of the gas measured by these authors consisted of matter foreign to the emanation itself.

To obtain pure emanation, radium bromide was either heated in a quartz tube or dissolved in water, the emanation being pumped off with the oxygen and hydrogen formed, and sparked down as described by Ramsay. The emanation was collected over potassium hydroxide, and condensed by cooling in liquid air. After all uncondensed gases had been pumped off, the emanation was allowed to gasify and remain some hours in contact with potassium hydroxide. It was finally liquefied again by liquid pentane at a temperature between 150° and 186° and exhausted by the pump, a portion being volatilised and lost in the process. Difficulty was experienced in obtaining the emanation free from carbon dioxide, although phosphoric oxide was used to lubricate the stopcocks and the emanation frequently stood twenty-four hours over potassium hydroxide. The emanation, as finally measured in a capillary tube, was in such a state of purity that the spectrum of carbon dioxide was hardly seen, but a new spectrum of bright lines certainly due to the emanation itself appeared.
The amount of radium corresponding with the amount of emanation measured was estimated by comparing the γ-ray activity of the emanation with that of a standard sample of radium bromide. When the emanation was well purified, its volume varied from 0.80 to 1.32 cub. mm. per gram of radium, decreasing rapidly and spontaneously to 0.58 to 0.66 cub. mm. The average final volume corrected for temperature and pressure was 0.58 cub. mm. The highly-purified emanation had the usual half-period of 3.75 days, and the author finds it difficult to explain the spontaneous contraction. In one experiment when purified emanation was left eleven days in the capillary, its volume greatly increased again, and a brilliant spectrum was obtained showing all the lines of helium. Passage of electric sparks caused the emanation to condense on the glass walls of the capillary, leaving only carbon dioxide. At the temperature of liquid air, the emanation has a sensible vapour pressure.

R. J. C.

Relative Activity of Emanation and Active Deposit from Thorium and from Actinium. Howard L. Bronson (Phil. Mag., 1908, [vi], 16, 291—299).—It is frequently assumed that each atom of the various radioactive substances gives off either one or no α-particle each time it undergoes transformation. The author's comparisons of the relative activity of emanation and active deposit in the cases of thorium and actinium, making due allowance for the different mean free paths of the α-particles in the various cases, fail to support this view.

A quantity of the volatile radioactive products from thorium or actinium was conveyed to the testing vessel by a current of air, and its total ionising activity was measured. After waiting a short time to allow the emanation to decay, the residual ionising activity due to the active deposit was measured. The activity of the emanation was obtained by difference. Knowing the rates of transformation of all the products, the activity of the deposit when at its maximum value could be calculated.

The ratio of ionisation due to active deposit to that due to emanation was found to vary from 0.34 to 0.40 in the case of thorium, and from 0.28 to 0.41 with actinium, different ratios being obtained with measuring vessels of different sizes.

The active deposit from thorium is supposed to contain thorium B and thorium C. In all cases with thorium, the calculated ionisation ratio was four times as great as the measured ratio, whilst with actinium the calculated ratio was always twice as great as the measured. The presence of other substances of short transformation periods would serve to explain the results, but there is no evidence for this (compare Hahn, Abstr., 1906, ii, 718). The author prefers to suppose that atoms of thorium B and thorium C give off the same number of α-particles during transformation, but that an atom of thorium emanation gives off four times as many; also, that a disintegrating atom of actinium emanation gives off twice as many α-particles as an atom of its active deposit. On the other hand, radium emanation, radium A, and radium C appear to give off the same number of α-particles per atom. The actual number of ejected
a-particles per atom cannot be stated as the determinations are only relative.

R. J. C.

Ozonisation of Air by the Action of Radium Salts and Emanation. RAFFAELO NASINI and MARIO G. LEVI (Atti R. Accad. Lincei, 1908, [v], 17, ii, 46—49).—The authors discuss the formation of ozone by radium salts, which is affirmed by Madame Curie and by Giesel, but denied by Ramsay and by Soddy. The authors' experiments show that, in presence of a large excess of air or oxygen, ozone is formed by the action of radium.

A small bottle containing 0.005 gram of radium bromide dissolved in 30 c.c. of water was placed open in a 5-litre flask containing air. When the flask was closed by a ground-glass stopper, after some hours the air inside gave the reactions of ozone, but if a cork or a rubber stopper was used, the air gave no odour or reactions of ozone, which had been destroyed.

Further experiments indicate that the emanation itself cannot produce ozone, but the results cannot be regarded as absolutely decisive.

T. H. P.

Action of Radium Emanation on Solutions of Copper Salts. MADAME MARIE CURIE and Mlle. GLEDITSCH (Compt. rend., 1908, 147, 345—349).—The authors have repeated Cameron and Ramsay's experiments (Trans., 1907, 91, 1593) on the action of radium emanation on copper salts, taking special precautions to employ apparatus and reagents free from traces of lithium. Platinum vessels were used, since it was found that distilled water free from lithium becomes contaminated with traces of this element when allowed to remain in contact with glass for twenty-four hours. The use of quartz vessels, especially of the transparent variety, is inadmissible, since these contain notable amounts of lithium. The water and acids necessary were distilled in platinum retorts, and the reagents were not allowed to come into contact with glass during the experiments. It was found practically impossible to remove the last traces of lithium from copper sulphate. After allowing the emanation to act on the solution, the copper was removed, and, after evaporation of the liquid, the residue, which weighed about 0.0004 gram, was examined spectroscopically. Sodium and potassium were found to be present, but lithium could not be detected. Comparative experiments on sodium sulphate containing known quantities of lithium sulphate indicated that the residue could not have contained more than $0.6 \times 10^{-5}$ milligram lithium. In order to show that no lithium was lost during the experiment, a control experiment was carried out on a solution containing 0.27 gram of copper and an amount of lithium sulphate equivalent to $1.7 \times 10^{-4}$ milligram of the chloride. After removal of the copper, lithium was readily detected in the residue.

The authors consider that the formation of sodium and lithium has not been established by Cameron and Ramsay.

W. O. W.

Retardation of $\alpha$-Rays by Metal Foils, and its Variation with the Speed of the $\alpha$-Particles. T. SMITH TAYLOR (Amer. J. Sci., 1908, [iv], 26, 169—179).—In the experiments of Bragg and
Kleeman, and also in those of Kučera and Mašek (Abstr., 1907, ii, 4), McClung (Abstr., 1906, ii, 138), Rutherford (Abstr., 1906, ii, 642), and Levin (Abstr., 1906, ii, 535), on the effect produced on the range of α-particles by the interposition of sheets of metals, the air equivalents corresponding with different positions of the screen were obtained by determining the difference of the range with the source of the rays uncovered and with the screen in place. As this method is not very accurate, a new method has been devised, and is described in the present paper.

Polonium was used as the source of the rays, and experiments were made with thin sheets of gold, lead, tin, aluminium, and silver of varying thickness. The results show that the air equivalents of sheets of metal foil decrease with the range, and hence with the speed, of the α-particles. The change is very small for thin foil of the lighter metals when the range of the α-particles is high, but for thicker sheets or a lower range, the change is more considerable. A comparison of the change for sheets of different metals of nearly equal air equivalents shows that the rate of change is in the order of the atomic weights of the metals.

E. G.

Charge and Nature of the α-Particle. Ernest Rutherford and Hans Geiger (Proc. Roy. Soc., 1908, 81, A, 162—173. Compare this vol., ii, 555).—The total charge carried by the α-particles expelled per second from a known weight of radium has been determined directly, and from the result and the number of α-particles expelled per second per gram of radium, the charge carried by an α-particle has been calculated as $9.3 \times 10^{-10}$ E.S. units. In determining the total charge carried by the particles, radium C was used as a source of radiation; the particles passed through aluminium plates into a testing chamber, and the current was measured in the usual way. The methods used to eliminate other rays, and to determine the strength of the radiating source, are fully described.

The charge carried by an α-particle, calculated on the assumption that the heating effect of radium is a measure of the kinetic energy of the α-particles expelled from it, is $9.1 \times 10^{-10}$ E.S. units, in good agreement with the above value. The charge $e$ carried by a hydrogen atom has been estimated by J. J. Thomson, H. A. Wilson, and others at $3-4 \times 10^{-10}$ E.S. units, from which it would follow that the charge on the α-particle is between $2e$ and $3e$. Reasons are given for the assumption that the values hitherto found for $e$ are too low. As the α-particle probably carries $2e$, the most probable value for $e$ is $4.65 \times 10^{-10}$ E.S. units. Support is lent to this view by a new calculation of $e$ from the known period of transformation of radium, the result obtained being $4.1 \times 10^{-10}$ E.S. units.

As the ratio of the charge on the α-particle to its mass has already been determined, the mass (atomic weight) of the α-particle has now been calculated as 3.84, which supports Rutherford’s previous suggestion that the α-particle, after it has lost its positive charge, is a helium atom.

From the data now available, some important radioactive magnitudes, such as the volume of the emanation and the rate of production of helium, have been calculated.

G. S.
Scattering of the α-Particles by Matter. Hans Geiger (Proc. Roy. Soc., 1908, 81, 4, 174—177).—Radium emanation was employed as a source of α-particles; these were allowed to pass through a narrow slit on their way to a phosphorescent screen, and from a comparison of the area reached by the rays (as determined by observing the scintillations) with the magnitude of the geometrical image of the slit, the amount of scattering could be ascertained.

In a vacuum, scarcely any scintillations were observed outside the image of the slit, but, when air was allowed to enter, the area of scintillation increased. The same effect was produced in a vacuum when the slit was covered with gold leaf, and to a smaller extent when aluminium foil was employed.

G. S.

Secondary γ-Rays due to γ-Rays of Radium C. A. S. Eve (Phil. Mag., 1908, [vi], 16, 224—234).—The intensity of secondary cathode radiation from various substances under the impact of Röntgen rays, β-rays, and γ-rays has been shown to be a function of the atomic weight of the secondary radiator, but comparison of Townsend’s determinations of secondary radiation, from various substances under the influence of X-rays, with the author’s values for the total secondary radiation produced by γ-rays, reveals striking discrepancies. The author has endeavoured to find the origin of these differences, which, if Röntgen rays and γ-rays are fundamentally of the same nature, ought not to arise.

Upwards of 30% of the secondary radiation may consist of secondary γ-rays with a penetrating power equal to that of primary γ-rays from actinium, but greater than that of primary γ-rays from uranium or radium. One or two millimetres of lead or aluminium suffice to absorb completely the secondary cathode rays from lead,* iron, or brick radiators, but allow the secondary γ-rays to pass. When comparative experiments are made in such a way that cathode secondary rays are absorbed and only secondary γ-rays reach the electroscope, the secondary effects produced by X-rays and γ-rays of radium are neither in order of the atomic weights nor of the densities of the radiators, and are not in agreement with one another. The secondary rays which reach the electroscope are γ-rays, and not penetrating cathode rays, since their intensity is not affected by a strong magnetic field.

The differences apparently lie more in the velocity than in the nature of the particles. Even cathode secondary radiation, which follows the order of the atomic weights, has a much higher velocity when excited by β- or γ-rays than by X-rays. The similarity of the β- and γ-ray effects in this instance is held to support Bragg’s theory that β- and γ-particles are essentially the same, but bear different charges.

The intensity of the secondary γ-rays induced by primary γ-rays from radium depends on the material surrounding the radium. Primary γ-rays traverse steel more readily than lead, but rays which have passed through steel are more readily absorbed by lead than rays which have already passed through lead. Taking the case of radium enclosed in a glass tube, the secondary radiation due to γ-radiation is 7.5% of that due to β- and γ-radiation together. Of this 7.5%, the
larger part is cathode secondary radiation, the proportion of \( \gamma \)-radiation in it being 6.2% from lead, 25% from iron, and 28% from brick.

The coefficient of absorption of primary \( \gamma \)-rays from radium is \( 0.45 - 0.57 \), from uranium 1.4, from actinium 2.7 - 4.7, whilst the secondary \( \gamma \)-rays excited by radium \( \gamma \)-rays in lead, iron, and brick have a coefficient about 4.6. The author is of the opinion that secondary \( \gamma \)-rays caused by the primary \( \gamma \)-rays of actinium would have a coefficient of absorption even lower than 4.6, and approximating to that of \( X \)-rays.

R. J. C.

Polonium Rays. Ch. Lattès (Chem. Zentr., 1908, i, 2137—2138; from Le Radium, 1908, 5, 97—102).—The author has endeavoured to obtain evidence of the production of secondary rays when polonium rays fall upon a metal plate by means of delicate electrical and photographic processes. In this he has been unsuccessful, although it is probable that secondary rays are produced (Logeman, Abstr., 1906, ii, 721), and should be photographically detectable.

J. V. E.

Radioactivity of Certain Goitrigenic Springs. Répin (Compt. rend., 1908, 147, 387—388).—Three samples of spring water from the neighbourhood of St. Jean de Maurienne were found to be distinctly radioactive \( (A = 0.011 \) to 0.031 in Curie-Laborde units). Endemic goitre is known to be prevalent in the districts where these waters are used for drinking purposes, and the author suggests that the well-known disappearance of goitrigenic properties which takes place after the lapse of time is connected with the decay in the radioactivity of the waters.

W. O. W.

Invisible Radiations from the Explosive Discharge in Air. I. Schincaglia (Nuovo Cim., 1908, [v], 15, 481—491).—An apparatus is described which allows of the very accurate regulation of a spark gap, in order to study the effect of radiations from another spark in causing the spark to pass. The transparency of various liquids to the invisible rays was examined by enclosing them in a quartz or selenite cell and interposing them between the spark gaps.

Whilst water and alcohol are transparent, metallic salts and many organic liquids, such as turpentine, carbon disulphide, and petroleum, are highly opaque, indicating that the radiation from the spark does not contain extreme ultra-violet rays.

C. H. D.

Radiation from Drying Oils. Werner Schmidt (Zeitsch. physikal. Chem., 1908, 64, 243—250).—Gum arabic when kept in the neighbourhood of linseed-oil varnish is found to undergo a slow change and becomes insoluble. If a gum solution contains a little chromate, the gum is rendered insoluble, rapidly when exposed to light, and more slowly when exposed to linseed-oil varnish in a dark room. This analogy between the action of light and the action of the drying oil is borne out by a study of the effect of the latter on a photographic plate. The radiation from the oil affects the plate even through slips.
of gelatin or paper, and if a perforated sheet of metal is interposed, an image is obtained. The phenomenon of solarisation has also been observed.

This behaviour of linseed-oil varnish is connected with the oxidation which goes on during drying, and which is possibly accompanied by the formation of ozone or other compounds of a superoxide character. It has been noticed that the bright surface of a metal plate exposed in the neighbourhood of a linseed-oil varnish shows evidence of oxidation.

J. C. P.

Formation of Mists in Presence of Radium Emanation. Madame Marie Curie (Compt. rend., 1908, 147, 379—382. Compare this vol., ii, 7).—The appearance of mists in moist gases induced by radium emanation appears to be due to the formation in the gases of chemical compounds capable of absorbing water vapour. The gases experimented on were contained in sealed glass bulbs illuminated by the electric arc. Air containing pure water vapour and charged with emanation gives a slight mist, persisting for several days; a mist is not produced when the air is replaced by carbon dioxide. If the water contains half its weight of sulphuric acid, an intense mist, lasting for several months, is produced whether the gas employed is air or carbon dioxide.

A permanent mist is also obtained in a bulb containing concentrated sulphuric acid and carbon dioxide; in a blank experiment without emanation, a still more intense mist was produced on warming the bulb, but this disappeared in less than a day. When caoutchouc stoppers are used to close the bulbs, the mists are very dense and persistent, probably through the oxidation of sulphur and organic matter giving rise to products capable of acting as centres of condensation. This is confirmed by the production of a fine, persistent mist in a bulb containing water, air, and emanation, with a fragment of sulphur kept out of contact with the water; at the end of the experiment, sulphuric acid is present in the water. The presence of nitric acid has also been detected when air has been used.

Similar mists are formed in air charged with light petroleum or carbon disulphide, and also in carbon dioxide containing anhydrous ether with emanation. In some instances, mists are formed when solids are employed; in these cases, a deposit is visible on the sides of the vessel. Emanation induces a mist in carbon dioxide containing iodine, or in air containing camphor; in the first instance, the mist subsides in a few days. Actinium causes a mist in moist carbon dioxide.

The drops constituting the mist in the foregoing experiments behave as if they had no electrostatic charge when introduced into an electric field.

W. O. W.

Supersaturation and Nuclear Condensation of Certain Organic Vapours. T. H. Laby (Phil. Trans., 1908, A, 208, 445—474; Proc. Roy. Soc., 1908, 81, A, 219—220).—Dust-free air, saturated with an organic vapour (ester, acid, or alcohol), was subjected to sudden adiabatic expansion in a special apparatus, and the least expansion required to produce condensation of the vapour noted. The
effect of the presence of ionic nuclei, obtained by previous exposure to Röntgen rays, on the conditions of condensation was also noted, as well as the different effects produced according as positive or negative ions were in excess.

The degree of supersaturation, $S$, existing at the end of the expansion has been calculated for a number of alcohols, esters, and acids; it is greatest for the acids and least for the alcohols. There is good agreement in some cases between the values of $S$ deduced from the expansions and those calculated on the accepted theory of condensation on ionic nuclei.

In the case of certain acids, greater expansion is necessary to produce condensation in the absence of ionic nuclei than when they are present. The positive ions are more efficient condensing agents than the negative for certain organic vapours, but water condenses more easily on negative ions.

Certain organic compounds, including alcohols and esters, become negatively charged when air is bubbled through them, but acetic acid becomes positively charged.

Influence of Traces of Nitrous Gases on the Condensation of Water Vapour. Erich Pringal (Ann. Physik, 1908, [iv], 26, 727—750).—The object of the experiments was to determine whether the condensing action of ordinary ozonised oxygen or air on water vapour is due to the presence of small quantities of nitrous gases. The experimental observations show that this is the case, and that pure ozone has no condensing action. In presence of water vapour, ozone appears to act on nitrogen and yield the condensation agent. Attention is called to the importance of these observations in connexion with the condensation of atmospheric water vapour.

Genesis of Ions by Collision of Positive and Negative Ions in a Gas. Experiments on Argon and Helium. E. W. B. Gill and F. B. Pidduck (Phil. Mag., 1908, [vi], 16, 280—290).—Townsend and Hurst (Abstr., 1905, ii, 7), assuming that positive and negative ions produce ionisation of a gas at definite rates, deduced an equation connecting gaseous conductivity and sparking potential with the gap between the electrodes. The authors have determined the minimum voltage required to produce a spark in argon or helium and the conductivity at various pressures in order to test the above theorem.

Each negative ion is supposed to produce a gaseous ions, and each positive ion $\beta$ gaseous ions, in moving through a centimetre. Experiments were carried out with gaseous pressures of 0·66 mm. to 13 mm. and various distances between the electrodes. The values of the constants $a$ and $\beta$ at any one pressure could be calculated from three conductivity measurements. The remaining conductivities at this pressure were found to be in satisfactory agreement with Townsend and Hurst's equation. Additional support for the theory is found in the extremely close agreement between the sparking potentials determined directly in argon and helium and the potentials calculated from conductivity measurements at lower potentials. The values of the constants $a$ and $\beta$ for argon are greater than for air, so that argon is
more readily ionised than air by both positive and negative ions. The helium employed was somewhat impure, but as the theory holds equally well for mixtures, values of $a$ and $\beta$ could be calculated. Even impure helium is more readily ionised than hydrogen, and, after purification by charcoal cooled in liquid air, the sparking potential of helium was lowered (compare Strutt, *Trans. Roy. Soc.*, 1900, *A*, 193, 377). On the other hand, purification of the argon employed did not affect the values obtained with it.

After the passage of one spark, a higher potential was required to pass another immediately. Passing a spark in the reverse direction facilitated recovery. This effect may be due to some kind of polarisation at the zinc electrodes.

**R. J. C.**

**Positive Electrons.** A. Bestelmeyer (*Physikal. Zeitsch.*, 1908, *9*, 541—542).—It has been found by J. Becquerel (this vol., ii, 751) that canal rays which are caused to pass through a small opening through which cathode rays are also passing are displaced in the immediate neighbourhood of the aperture under the influence of a magnetic field. Becquerel's conclusion, that the canal rays are temporarily transformed into positively-charged carriers as the result of contact with the cathode rays, is refuted by the author. The phenomenon can be satisfactorily explained by the electrostatic charge which the walls of the aperture receives as the result of bombardment by the cathode rays. In consequence of the action of this electrostatic charge, the canal rays are caused to deviate from their rectilinear paths.

**H. M. D.**

**Experimental Investigation of the Stratified Positive Glow.** R. Holm (*Physikal. Zeitsch.*, 1908, *9*, 558—562).—Measurements have been made of the potential gradient and the distance between adjacent strata of the positive glow in the discharge through hydrogen, nitrogen, and helium. Curves are plotted which show the dependence of these two factors on the current intensity. Almost identical results are obtained whether the method of Stark or that of H. A. Wilson is employed.

**H. M. D.**

**Cathodic Volatilisation of Metals in Attenuated Gases.** Volkmar Kohlschütter (*Zeitsch. Elektrochem.*, 1908, *14*, 417—421).—Fischer and Hähnel (this vol., ii, 653) have found that the volatilisation of a metal is the same in argon and hydrogen when the same current is used, whereas Kohlschütter and Goldschmidt (this vol., ii, 457) found large differences.

The author now shows that the results depend on the kind of current used. Two different induction coils are used: (A) a coil with a high resistance primary and low resistance secondary winding, and (B) an ordinary Ruhmkorff coil. Using platinum cathodes in tubes filled with hydrogen and argon respectively and connected in series, he finds that the quantity of platinum volatilised in argon is from four to twenty-two times as much as that volatilised in hydrogen.

The ratio of the quantities volatilised in argon and in hydrogen
is increased by increasing the pressure of the gas and the current strength when one coil is used, but decreased with the other coil. Hence the results obtained appear to depend entirely on the peculiarities of the induction coil employed.

T. E.

Volatile of Cathodes in Attenuated Gases. Franz Fischer and Otto Hahnel (Zeitsch. Elektrochem., 1908, 14, 433—437; Volkmar Kohlschütter, ibid., 437—439).—These papers contain the numerical data on which the statements already published (this vol., ii, 653) are founded, and a reply by Kohlschütter (compare preceding abstract).

T. E.

Electrical Conductivity of Mixtures of Alcohol and Water. Antony G. Doroschewsky and M. S. Roschdestvensky (J. Russ. Phys. Chem. Soc., 1908, 40, 887—908).—After discussing previous work on this subject, the authors give the results of their own measurements.

The values obtained for the conductivities of aqueous-alcoholic solutions of various concentrations at 15° are quite different from those given by Pfeiffer (Abstr., 1885, 1029; 1886, 4, 115), as also is the form of the curve connecting the conductivity with the percentage of alcohol by weight. The curve obtained by the authors not only exhibits no evidence of the existence of definite hydrates of alcohol, but has no singular points. In some respects it resembles the curves connecting the composition of aqueous-alcoholic solutions with other properties, such as the specific gravity and boiling point, the curve falling sharply at both ends and remaining almost horizontal in the middle of its course; there is a slight rise corresponding with about 80% of alcohol.

When the concentration of the alcohol is expressed in grams per 100 c.c. of solution, the electrical conductivity follows the law

\[ K = c \]

The electrical conductivities of aqueous solutions of alcohol are directly proportional to the dielectric constants of the solutions, and inversely proportional to their viscosities.

T. H. P.

Electrical Conductivity of Liquid Sulphur. Albert Wigand (Ber. deut. physikal. Ges., 1908, 6, 495—508).—The author has made measurements of the electrical conductivity of liquid sulphur, in order to ascertain whether this is altered under the influence of light. The experiments were suggested by the fact that liquid sulphur, like solid selenium, consists of a mixture of two modifications in equilibrium, and that in the case of selenium, displacement of the equilibrium takes place under the influence of light in the direction of the formation of a larger proportion of the modification which has the greater conductivity. The results are negative, and indicate that the electrical conductivity of the soluble and insoluble forms of sulphur is the same.

Measurements of the conductivity at temperatures ranging from 130° to 446° show that this increases regularly up to 150°, where it reaches a maximum; it then falls, attaining a minimum value between
160° and 170°, above which it increases up to the boiling point. The view is expressed that the measured conductivity is really due to traces of foreign substances which are ionised in the molten sulphur.

H. M. D.

**Effect of Concentration on the Temperature of Maximum Electrolytic Conductivity of Weak Electrolytes with Negative Heat of Dissociation.** Henrik Wegelius (Zeitsch. Elektrochem., 1908, 14, 514—518).—Solutions of hypophosphorous acid \( \text{H}_3\text{PO}_3 \) have a maximum conductivity at 72° for 5·75 \( \text{N} \), 54° for 1·25 \( \text{N} \), 52° for 0·955 \( \text{N} \), 70° for 0·328 \( \text{N} \), 87·5° for 0·12 \( \text{N} \). With weaker solutions, the temperature of maximum conductivity is higher than 100°. Phosphoric acid gave maxima at 77° for 2·715 \( \text{N} \), 70° for 1·955 \( \text{N} \), and at 79° for 0·217 \( \text{N} \); weaker and stronger solutions showed no maximum at temperatures below 93°. An approximate theory showing how the temperature of maximum conductivity depends on the changes of dissociation and of ionic mobility with the temperature is given.

T. E.

**A New Primary Voltaic Cell of the Daniell Type.** James Strachan (Chem. News, 1908, 98, 102).—The cell consists of an outer jar in which are placed a number of carbon rods connected by a leaden cover, through which passes a porous pot containing an amalgamated zinc rod immersed in a hydrochloric acid solution of zinc and ammonium chlorides. The outer jar contains an acid solution of lead tetrachloride prepared by dissolving freshly-precipitated lead peroxide in cold concentrated hydrochloric acid, or by adding concentrated hydrochloric acid to a mixture of lead acetate and bleaching powder contained in a pressure bottle and rapidly sealing the latter. Such a solution acts as a rapid depolariser, and is constant in its action; the cell has a higher \( \text{E.M.F.} \), but a much lower resistance, than a Daniell cell. The disadvantage of the cell due to the escape of chlorine may be overcome by sealing the space between the leaden cover and the porous pot with paraffin wax. The zinc may be replaced by iron, but the \( \text{E.M.F.} \) drops then from 1·5 to 0·95.

P. H.

**Gas Electrodes. I. Nitric Oxide.** Ugo Grassi (Nuovo Cim., 1908, [v], 15, 467—480).—The potential of a platinised platinum electrode, saturated with nitric oxide, was measured against a normal calomel electrode. In acid solutions, the electrode is stable, and its potential is independent of the rate of passage of the gas; in alkaline solutions the difference of potential changes sign in the first minute, and only attains its final value slowly. This is due to the conversion of the oxide into alkali nitrite and nitrous oxide, which is greatly accelerated by platinum. The first stage of the reaction is the formation of sodium nitrohydroxylaminate: \( 2\text{NO} + \text{Na}_2\text{O} = \text{ON} : \text{N}(\text{ONa})_2 \), which then decomposes according to the equation \( 2\text{Na}_2\text{N}_2\text{O}_3 + \text{H}_2\text{O} = 2\text{NaNO}_2 + 2\text{NaOH} + \text{N}_2\text{O} \). Quantitative experiments show that the nitric oxide reacts in solution as a double molecule. In acid solutions, the cell \( \text{H} - (\text{NO})_2^- \text{NO} \) has an \( \text{E.M.F.} \) of 0·80 volt, nitric oxide being positive to hydrogen.

C. H. D.
Potential of a Hydrogen Electrode in Acid and Alkaline Solutions. C. L. A. Schmidt and C. P. Finger (J. Physical Chem., 1908, 12, 406—416).—The authors have measured the potential of a hydrogen electrode in a series of solutions, each containing 0·25 gram-atom of boron per litre and prepared by mixing solutions of boric acid and borax or sodium hydroxide in different proportions. From the values of the potential difference, the hydrogen-ion concentrations are calculated, and a series of readily reproducible standards for the colorimetric determination of the strengths of acids and bases has been provided.

From the form of the curve, which is obtained by plotting the potential differences against the percentage amount of the hydrogen of the boric acid which is replaced by sodium, the conclusion is drawn that the compound NaH$_2$BO$_3$ (or its anhydride, NaBO$_2$) is the only one formed to any appreciable extent when solutions of boric acid and sodium hydroxide are mixed. This conclusion is in agreement with the results of thermochemical and freezing-point measurements.

H. M. D.

Solid Electrolytes. Their Decomposition by a Current and their Electromotive Properties in Galvanic Chains. Fritz Haber (Ann. Physik, 1908, [iv], 26, 927—973).—Part of this paper represents a summary of work which has been published in detail previously (compare Haber and Tolloczko, Abstr., 1904, ii, 813; Haber and Moser, Abstr., 1905, ii, 667; Haber and Foster, Abstr., 1907, ii, 66; Haber and Fleischmann, Abstr., 1907, ii, 6; Haber, Rieff, and Vogt, this vol., ii, 254).

In the third section [with G. Birstein], experiments on the electrolytic decomposition of solid salts of the alkali metals are described. Pure potassium chloride yields at the cathode a violet substance which dissolves in water with evolution of hydrogen. It is not acted on by anhydrous ethyl alcohol. The eutectic mixture of potassium and sodium chloride yields a yellowish-brown substance with the same properties. On electrolysing a mixture of sodium chloride and carbonate, carbon separates at the cathode. Potential measurements are recorded which support the view that the coloured substances formed at the cathode are sub-chlorides of the alkali metals.

The last section of the paper [with R. Beutner] deals with the potential differences at the surfaces of contact of solid electrolytes and of solid salts and their saturated solutions. Application is made of Nernst’s theory of potential differences to the special systems under investigation, and a number of theoretical deductions are made.

H. M. D.

T. E.

shown in a previous paper that the progressive diminution in the equivalent conductivity of dilute sulphuric acid with dilution when the concentration is less than 0.0005—0.001 gram-equivalent per litre is still observed when the solvent is boiled repeatedly under low pressure and the air re-admitted through potash bulbs (to remove carbon dioxide), and it is now shown that the diminution in question persists when the air is re-admitted through bulbs containing dilute sulphuric acid and potassium hydroxide respectively.

The observed diminution in the equivalent conductivity could be accounted for if the H⁺ ion travels more slowly in dilute than in concentrated solutions, and to test this point the transport ratio of solutions of different concentration has been determined by a modification of the ordinary method, the changes in concentration round the electrodes due to electrolysis being determined by measuring the conductivity of the solution; in the case of the very dilute solutions, with pairs of electrodes placed in the anode and cathode compartments respectively. Although a change in the expected direction was actually observed, the transport ratio apparently increasing from 0.186 to 0.202 on progressive dilution, it is not considered probable that this is due to a change in the relative migration velocity of the ions, but to some alkaline or saline impurity in the water. As the effect in question is not removed by boiling, the impurity might be ammonium carbonate, but the matter is not regarded as being finally settled.

G. S.

Electrolysis of Copper Solutions. Jean Meyer (Bull. Soc. chim. Belg., 1908, 22, 259—291).—The author attempts to find a more satisfactory explanation of the anomalous behaviour of the copper voltameter than that provided by the theories of Foerster, Abel, and others. The Foerster-Seidel theory requires that a gram-molecule of cuprous oxide for each 2 × 96540 coulombs should be formed on electrolysis a hot solution of copper sulphate at a lower potential than that required for the deposition of copper; on repeating these authors' experiments, however, it was found that the weight of the oxide was less than half this. Similar results were obtained when operating in absence of air, hence the deficit cannot be due to oxidation to copper sulphate. When the electrolysis is carried out at 90°, a green basic salt of variable composition is precipitated; this compound, which appears to be identical with that obtained by boiling an aqueous solution of copper sulphate, probably arises from dissolution of the cuprous oxide in the copper sulphate solution. This secondary dissolution of the oxide, which is independent of the current and the concentration of the ions, explains the presence of a cuprous salt, and evidence is adduced to show that it accounts for the formation of cuprous oxide at both electrodes. At the cathode, the following reaction is supposed to occur: \( \text{Cu} + \text{CuSO}_4 + \text{H}_2\text{O} \rightarrow \text{Cu}_2\text{O} + \text{H}_2\text{SO}_4 \). The same principle is applied to cover the phenomena observed when solutions of cupric chloride are electrolysed.

It was found possible to estimate the amount of cuprous oxide in the metallic deposits by treating the mixture with a neutral
solution of ferric alum, which, after being acidified with sulphuric acid, was titrated by permanganate.

It is pointed out that Bose’s phenomenon cannot be due to the partial discharge of cupric ions: \( \text{Cu}^{++} \rightarrow \text{Cu}^{+} \), as Abel has suggested, since, by electrolyzing a hot acid solution of copper sulphate in absence of oxygen and operating with currents of low density, a good yield of pure copper is obtained, the dissolution of copper in copper sulphate solution being accomplished as readily in acid as in neutral solution (compare Heiberg, Abstr., 1903, ii, 263).

In the hope of obtaining a perfect voltametric solution, hydrogen peroxide, instead of sulphuric acid, was added to the copper sulphate in order to prevent the formation of cuprous salts. The results, however, were not satisfactory, probably owing to the formation of persulphates and catalytic decomposition of the hydrogen peroxide at the electrodes.

W. O. W.

Reversed Electrolysis. J. W. Turrentine (J. Physical Chem., 1908, 12, 448—467).—A number of apparently anomalous electrolytic phenomena, which are in reality due to secondary reactions, have been examined. When a current is passed through a solution of sodium sulphate between a magnesium anode and a platinum cathode, hydrogen is evolved at the anode, which becomes covered with scales of magnesium hydroxide. It is supposed that the magnesium dissolves at the anode as a univalent metal, a secondary reaction then taking place in accordance with the equation:

\[
\text{Mg}_2\text{SO}_4 + 2\text{H}_2\text{O} = \text{MgSO}_4 + \text{Mg(OH)}_2 + \text{H}_2
\]

In a similar way, hydrogen is evolved at an aluminium anode in the electrolysis of a solution of sodium chloride. It is not possible to determine the effective valence with which solution takes place.

When a solution of potassium permanganate acidified with sulphuric acid is electrolysed between platinum electrodes, the gas evolved at the cathode contains a considerable proportion of oxygen. This has been traced to the decomposition of hydrogen peroxide formed by the electrolytic reduction of manganese dioxide.

H. M. D.

Migration of Ions in Heterogeneous Systems. Karl Spiro and Lawrence J. Henderson (Zeitsch. Chem. Ind. Kolloide, 1908, 3, 91—92).—Solutions of phosphates, carbonates, and globulins of the same composition are separated by a membrane, on one side of which a substance such as calcium carbonate, magnesia, or globulin is suspended. When carbon dioxide is passed through the solution which does not contain the suspended matter, its alkalinity to methyl-orange increases; the increase is diminished by passing in oxygen. This arrangement behaves in the same way as blood, and the experiments show that the phenomena are due to simple diffusion, and the assumption of a selective permeability of the walls of the red corpuscles under the influence of carbon dioxide is unnecessary.

T. E.

and insoluble carbonates in the presence of water is due to the
ionisation of the soluble salt; thus in the case of potassium chloride
and barium carbonate a small part of the dissociated salt reacts with
the barium carbonate to form barium chloride and potassium
carbonate.

M. A. W.

Estimation of the Hydration of Ions from Measurements of
Electromotive Forces. Gilbert N. Lewis (Zeitsch. Elektrochem.,
—The E.M.F. of a concentration cell depends on the ratio of the
“activities” of both the electrolyte and the water in the two
solutions (this vol., ii, 16), and on the numbers of ions and molecules
of water transported by the current. A measurement of the E.M.F.
of a cell in which the electrolyte has the same concentration in each
solution and therefore the same activity, whilst the activity of the
water in one solution is altered by the addition of a non-electrolyte,
should make it possible to estimate the number of molecules of water
carried along with the ions of the electrolyte.

T. E.

Improved Apparatus for the Measurement of Trans-ference Numbers in Solutions of the Halogen Acids and
their Salts. Edward W. Washburn (Technology Quart., 1908, 21,
164—177).—The essentially new features of the author’s apparatus
are represented by the special form of the silver anode and the silver
halide cathode. The anode consists of a silver wire wound into a
flat spiral, which is placed at the bottom of a Soxhlet extraction
cartridge, this being filled with small crystals of electrolytic silver,
which are packed tightly round the silver wire. This arrangement
gives an electrode of very large active surface. Using a cartridge
6 cms. long and 1·9 cms. in diameter, an electrode prepared in
this way will carry a current of 0·1 ampere for sixteen hours without
the formation of the slightest trace of acid or of colloidal silver
chloride.

The cathode consists of a silver disk prepared by making it the
anode in the electrolysis of a solution of sodium chloride. The disk,
which just fits into the apparatus, is covered with a layer of silver
chloride, obtained by precipitating a hot solution of silver nitrate with
excess of an alkali chloride solution. An electrode, 2·3 cms. in
diameter, is able to carry a current of 0·5 ampere without the evolution
of hydrogen or the formation of the slightest trace of alkali.

The anode and cathode tubes of the apparatus are provided with
stopcocks, and are connected by means of a ground-glass joint.

H. M. D.

Hydrolysis of Salts in Solution: Lecture Experiment.
Bartolo L. Vanzetti (Gazzetta, 1908, 38, ii, 98—99).—The following
simple experiment renders evident the phenomenon of hydrolysis of
salts. A test-tube is filled to about three-fourths of its height with a
5—10% gelatin solution containing faintly alkaline phenolphthalein.
When the gelatin has solidified, a 10% ferric chloride solution is
poured on to it. As diffusion into the gelatin proceeds, two strata become more and more distinct, the lower one being colourless, owing to the more rapid diffusion of the acid liberated by hydrolysis, and the less advanced, opaque one consisting of ferric hydroxide. Salts, such as nickel chloride or copper sulphate, containing a coloured ion may also be used.

**Change of Colour of Phenolphthalein.** Rudolf Wegscheider [with A. Schugowitsch] (Zeitsch. Elektrochem., 1908, 14, 510—512. Compare Abstr., 1904, ii, 512; this vol., ii, 646). — The concentration of the red ions in dilute alcoholic solutions containing known quantities of phenolphthalein and sodium hydroxide is determined by comparison of the colour with solutions containing an excess of sodium hydroxide. It is found that the expression \([RH][OH']/R'\) (where \(R'\) represents the phenolphthalein ion) is only approximately constant when there are more than two molecules of sodium hydroxide for each molecule of phenolphthalein in solution. On the assumption that the red salt contains two atoms of sodium (Abstr., 1905, i, 440), and that it is hydrolysed thus: \(R'^+H_2O\rightleftharpoons RH^'+OH'\) and \(RH^'+H_2O\rightleftharpoons RH_2+OH'\), a satisfactory explanation of the results obtained is possible.

**New Method for Determining the Specific Heats of Liquids.** Theodore W. Richards and Allan Winter Rowe (Zeitsch. physikal. Chem., 1908, 64, 187—200). — The liquids, the specific heats of which are to be compared (for example, water and a salt solution), are successively put in the calorimeter, and a definite quantity of heat is developed each time by neutralising a given quantity of acid with alkali in a platinum vessel, which is immersed in the liquid of the calorimeter. The calorimeter itself is completely surrounded by a jacket, the temperature of which is constantly adjusted to the changing temperature of the calorimeter (see Richards, Henderson, and Forbes, Abstr., 1905, ii, 677; Richards, Henderson, and Frevert, Abstr., 1907, ii, 604). The rise of temperature, therefore, in the calorimeter takes place adiabatically. The same apparatus may obviously be employed in the determination of heats of dilution.

One or two experiments made with this apparatus are recorded. The specific heat of a hydrochloric acid solution of the composition HCl + 200H_2O has been found to be 0.9809, and the maximum deviation from this figure in four independent experiments was 0.03%. The heat developed when a solution of the composition NaOH + 5.85H_2O is diluted until it has the composition NaOH + 43.5H_2O is 3.79 kilojoules.

**Specific Heats and Heats of Fusion of Isomorphous Substances and their Mixtures.** A. Bogojawlensky and N. Winogradoff (Zeitsch. physikal. Chem., 1904, 64, 251—254). — The authors have determined the specific heats and latent heats of fusion for mixtures of (1) m-chloronitrobenzene and m-bromonitrobenzene, (2) α-chlorocinnamaldehyde and α-bromocinnamaldehyde, (3) azobenzene and dibenzyl. They find that the specific heats of these
isomorphous mixtures, in both the liquid and the solid state, can be calculated by the mixture rule. In the first two cases, the latent heat of fusion \( f \) can be calculated by the mixture formula
\[
\frac{f}{(f_1 p_1 + f_2 p_2)} = \frac{(p_1 + p_2)}{(p_1 + p_2)}
\]
in fair agreement with the observed values, but in the third case there are marked discrepancies, the observed values being regularly less than the calculated values. It is noted that only in this third case does the freezing-point curve exhibit a minimum, and that the discrepancies referred to are similar to those observed with substances which form a eutectic mixture.

J. C. P.

Specific Heat of Mercury. W. A. KURBATOFF (J. Russ. Phys. Chem. Soc., 1908, 40, 811—813).—The results of a number of measurements show that the mean specific heat of mercury from \( 0^\circ \) to \( 306^\circ \) is \( 0.0325-0.0331 \). This value, together with that previously obtained by the author (Abstr., 1903, ii, 130), and those of other investigators, prove that the specific heat of mercury rises distinctly as the boiling point is approached.

In general, the specific heat of substances, the molecules of which do not change from the melting point to the critical temperature, is represented by a curve approximating to a straight line, and the true specific heat is the minimum between these two temperatures.

T. H. P.

Specific Heat of Alcohol and of its Mixtures with Water. Antony G. Doroschewsky and Adam W. Rakowsky (J. Russ. Phys. Chem. Soc., 1908, 40, 860—886).—The authors discuss the various formulae which have been proposed for expressing the specific heat of alcohol at different temperatures, and come to the conclusion that all these formulae refer, not to absolute alcohol, but to alcohols containing small, and probably varying, proportions of water. For carefully dehydrated alcohol, the value \( 0.6597 \) is obtained as the mean specific heat at \( 22-99^\circ \); this gives the value \( 0.518 \) for the specific heat at \( 20^\circ \), taking the value \( 0.0035 \) given by Hirn’s measurements (Ann. Chim. Phys., 1867, [iv], 10, 32) for the temperature-coefficient (between \( 20^\circ \) and \( 100^\circ \)). For the alcohol used by the authors, \( D_{1.0}^1 \) 0.79426 and \( k \) at \( 15^\circ \) is \( 0.097 \times 10^{-6} \) ohms.

In general, the changes of specific heat \( C \) of mixtures of alcohol and water with temperature are irregular. Thus, for \( 10—40\% \) aqueous alcohol solutions, \( C_{0.15} > C_{0.30} > C_{0.45} < C_{0.54} < C_{0.98} \), and for \( 10—20\% \) solutions, \( C_{0.15} > C_{0.98} \).

For solutions containing \( 100—50\% \) of alcohol, the specific heat is expressed by the equation: \( C = 0.6628 + 0.007945 (100 - p) - 0.000045 (100 - p)^2 \), where \( p \) represents the \% of alcohol by weight in the solution. For \( 50—20\% \) solutions, \( C = 0.9475 + 0.005164 (50 - p) - 0.0000625 (50 - p)^2 \), and for \( 20—0\% \) solutions, \( C = 1.0455 - 0.00104 (20.09 - p) - 0.0000482 (20.09 - p)^2 \).

The authors’ results show that Thomson’s supposition (Thermochem. Untersuch., 1882, vol. i, 74), that at their boiling points the heat effect of the formation of aqueous-alcoholic solutions is zero, is not general, but applies only to one definite solution. The temperature
at which the mixing has a zero heat effect is below the boiling point for strong solutions, and above the boiling point for dilute solutions of alcohol.

T. H. P.

Equation of Condition for Metals: Correction. Max Thiesen (Ber. deut. phys. Ges., 1908, 6, 604).—According to Grüneisen (this vol., ii, 563), for those metals which have been sufficiently investigated, the relation between the specific heat and the coefficient of expansion is nearly independent of the temperature. In deriving the form of the temperature function of these two magnitudes (this vol., ii, 659), the author assumed that the $\theta$ of equation $4$ (loc. cit.) was a pure temperature function, an assumption which is not justified. The value of $\theta$ is given only by a partial differential equation, which leaves the form of the temperature function undetermined. The relations given by the author do not, therefore, follow as consequences of Grüneisen's experimental law, but must be tested by direct experiment, as has been done in the case of platinum.

T. H. P.

Melting-point and Freezing-point Curves of Binary Systems when the Solid Phase is a Mixture (Amorphous Solid Solution or Mixed Crystals) of the Two Components. Johannes J. van Laar (Zeitsch. physikal. Chem., 1908, 64, 257—297).—A mathematical discussion of the possible forms of curve. In the case of optical isomerides and tautomeric substances, a minimum or eutectic point in the freezing-point curve is impossible (compare Roozeboom, Abstr., 1899, ii, 355, 401). When a racemic compound is formed, two eutectic points are possible. The formation of liquid mixed crystals is also discussed.

In Tammann's method of representing the total heat-content of binary systems (this vol., ii, 660), the heat of mixing may only be neglected in comparison with the heat of fusion so long as only stable systems are dealt with. In the labile region below the eutectic point, the heat of mixing may be considerable.

C. H. D.

Reciprocal Salt-pairs. I. Ernst Jänecke (Zeitsch. physikal. Chem., 1908, 64, 305—327. Compare Meyerhoffer, Abstr., 1901, ii, 639).—The conditions occurring in the melting and solidifying of reciprocal pairs of salts, in which there is an equilibrium $M'R' + M''R'' \rightleftharpoons M'R'' + M''R'$, when only one liquid phase is present, are discussed for the two cases: (a) when the only solid phases are the four salts; (b) when only two isomorphous mixtures separate. The equilibrium diagrams for case (a) are completely discussed. In case (b) there are many possibilities. The simplest conditions occur when the melting points of each pair of reciprocal salts have neither a maximum nor a minimum point; the whole system may then be broken up into two ternary systems.

The eutectic curve between the two solid phases may be without any maximum or minimum, or may have either a maximum or a minimum. The last of these cases is illustrated by the system $(K_2Na_2)-(Cl_2SO_4)$ (this vol., ii, 841).

C. H. D.

The melting-point curves obtained in cases (1) and (2) show that complete series of mixed crystals are formed; the melting-point curves obtained in cases (3) and (4) exhibit a minimum, but it is not certain whether this is an eutectic or not; in cases (5), (6), and (7) the melting-point curves are all marked by eutectics; in cases (8) and (9) the melting-point curves were not traced.

The clearing-point curves show that in all cases the fluid-crystalline phases are completely miscible. The direction of these curves depends exclusively on the clearing points of the two components, and is independent of the course of the melting-point curve. Hence it comes that, as in cases (1) and (2), two substances the clearing points of which lie below their respective melting points form fluid-crystalline mixtures within certain limits of concentration. In cases where the labile clearing point of one component cannot be determined directly, owing to the impossibility of supercooling, it may be ascertained by extrapolating the clearing-point curve, which in the majority of cases is nearly a straight line.

The melting points and clearing points for various azo- and azoxy-compounds are as follows, the melting point being given first in each case: azoanisole 164·1°, 108·0°; azophenetole, 160·2°, 156·1°; n-dipropylazophenol, 146·1°, 112·0°; ethyl-n-propylazophenol, 144·2°, 139·6°; methylethylazophenol, 134·5°, 132·2°; methyl-n-propylazophenol, 113·1°, 110·0°; azoxyphenetole, 136·9°, 167·5°; azoxyanisole, 117·4°, 134·4°; n-dipropylazophenol, 116·0°, 122·0°; azoxyanisolephenetole, 93·5°, 149·6°. It will be observed that all the azo-compounds are monotropic, that is, their clearing points lie below their melting points, whilst the azoxy-compounds are enantiotropic.

J. C. P.

Inverse Melting Points. J. N. Brönsted (Zeitsch. physikal. Chem., 1908, 64, 374—377).—The course of the solubility curves for the hydrates of ceric sulphate (Koppel, Abstr., 1904, ii, 819) indicates that two of the hydrates, Ce₂(SO₄)₃·9H₂O and Ce₂(SO₄)₃·5H₂O, are only stable at higher temperatures, passing into the octahydrate and the tetrahydrate at 35° and 100° respectively. Since this would mean the conversion of a solid hydrate into a lower hydrate and an aqueous solution on cooling, the temperatures mentioned may be regarded as inverse melting points. Such fusion on cooling was not directly observed, but is a thermodynamical consequence of the position of the solubility curves.

It is shown on theoretical grounds that inverse melting points can
only occur when, as is the case with ceric sulphate, the solubility of the salt diminishes with increasing temperature. C. H. D.

A Modification of the Cryoscopic Method for Investigating Small Quantities of liquid. Tōsaku Kinoshita (Biochem. Zeitsch., 1908, 12, 390—406).—With certain modifications, the Beckmann method can be applied to small quantities of liquid. The chief of these consists in enveloping the thermometer bulb with a thin layer of paraffin, ash-free filter-paper, and sheet-rubber. S. E. S.

Analysis of the Lowering of the Freezing Point in Physiological Fluids. II. Lowering of the Freezing Point of Suspensions. Ernst Tezner and Johann Roska (Zeitsch. physiol. Chem., 1908, 56, 495—506).—The depression of the freezing point of water by the addition of a fatty acid is not nearly so marked when solid particles, such as blood-charcoal or casein, are suspended in the solution. This effect is attributed to adsorption, which produces a concentration of the solute around the solid particles, and thus diminishes the concentration of the rest of the solution.

The adsorption depends mainly on the surface tension, and this again on the concentrations of the various dissolved materials, but is not directly proportional to their osmotic concentrations. Hence the lowering of the freezing point of such solutions is not a simple function of the osmotic concentration.

Negative adsorption is not met with. The process of filtration yields a liquid with the same or greater lowering of the freezing point, according as the filtration is more or less complete. J. J. S.

Influence of the Rate of Cooling on the Composition of Saturated Mixed Crystals. W. von Lepkowski (Zeitsch. anorg. Chem., 1908, 59, 285—292).—Experiments have been made to ascertain whether molten alloys of bismuth and tin and of copper and silver give rise to mixed crystals when rapidly cooled. The supersaturation phenomena requisite for the production of these crystals are found in the case of bismuth-tin alloys, but not in the case of copper-silver alloys.

Alloys containing up to a little more than 1% of tin show no trace of the eutectic mixture when rapidly cooled, but this is found if the percentage of tin exceeds 1.5. The supersaturated mixed crystals, which are formed in the first case, are unaltered by exposure for six hours at 120°.

The difference in behaviour of bismuth compared with copper and silver is attributed to the greater velocity of crystallisation of the supercooled metal in the case of bismuth. H. M. D.

Vaporisation. II. Hanns von Jüptner (Zeitsch. physikal. Chem., 1908, 63, 579—618. Compare this vol., ii, 663).—Starting with van der Waals’ equation, the author deduces formulæ for the calculation (1) of the internal pressure, \( \pi = a/v^2 \), due to molecular attraction; (2) of the fraction of the total volume actually occupied by the molecules. The values of these are then deduced for a large number
of substances. It is found that the value of $a$, in general, increases with the molecular weight, although constitutive influences make themselves felt. From these values of $a$, the critical constants are calculated, and the expressions $(p_k + \pi_k)/p_k = A$ and $v_i/v_k = B$ [$v_i =$ ideal volume] are evaluated. It is shown that, in general, $A$ increases with $B$. The question how far these various quantities are affected by molecular association at the critical temperature is also discussed. The term $b$ in van der Waals’ equation is regarded as variable with the temperature and internal pressure, possibly also with the attraction of neighbouring molecules.

**Determination of Vapour Pressures of Solutions with the Morley Gauge.** Olin F. Tower (J. Amer. Chem. Soc., 1908, 30, 1219—1228).—The methods most commonly used for determining the vapour pressures of solutions are of two kinds, which may be distinguished as the “differential” and the “dynamic” methods. In the former, the difference between the two vapour pressures, such as that of a given solvent and one of its solutions, is measured by means of a suitable gauge, whilst the latter method is based on the principle that when air, or some other inactive gas, is saturated with the vapour of the liquid or solution, the following relation holds: total volume/volume of the aqueous vapour = total pressure/pressure of the aqueous vapour. Ostwald has simplified this method by allowing the air to bubble first through the solution and then through pure water.

A method has now been studied which is of the “differential” class, and resembles that of Smits, except that his micromanometer is replaced by a mercury gauge, designed by Morley (Amer. J. Sci., 1902, 13, 455) for measuring small differences of pressure. Determinations have been made of the vapour pressures of aqueous solutions of sucrose, potassium iodide, and lithium chloride, and of methyl- and ethyl-alcoholic solutions of tetraethylammonium iodide, potassium iodide, and lithium chloride. The results are tabulated.

It has been found that this method involves several difficulties and sources of error. The readings vary considerably, and it is therefore necessary to make a great many readings and take the average. The time occupied in this way, and also in repairing breaks and overcoming other difficulties, is very great. Moreover, the solutions must always be maintained at a temperature lower than that of the gauge. For these reasons, this “differential” method is regarded as less trustworthy, and subject to more limitations than the “dynamic” or air-bubble method.

**Osmotic Researches.** I. Ernst Cohen and J. W. Commelin (Zeitsch. physikal. Chem., 1908, 64, 1—52).—The authors review the attempts which have been made to measure osmotic pressure directly, and criticize in detail Kahlenberg’s experimental methods and conclusions (Abstr., 1906, ii, 337). An osmotic apparatus has been devised in which the weaknesses of Kahlenberg’s osmometer are remedied, and with which the osmotic pressure of sucrose in pyridine has been determined. As in Kahlenberg’s experiments, the semi-permeable membrane was of India-rubber. The authors show that it
is immaterial whether the contents of the osmotic cell are stirred or not. It has not been found possible to get consistent values for the osmotic pressure in parallel experiments, and all the pressures recorded were far below the theoretical values. The authors consider it probable that water is responsible for the irregular results obtained, for it has been found that the presence of water either in the solution or in the pure solvent exerts a very marked influence on the observed pressure. Fresh experiments are therefore planned in which perfectly anhydrous pyridine will be employed.

J. C. P.

The Avogadro-Guldberg Law. W. A. Kurbatoff (J. Russ. Phys. Chem. Soc., 1908, 40, 813—817).—It was shown by Guldberg that the absolute boiling points of different substances represent "corresponding" temperatures, as they are always two-thirds of the absolute critical temperatures. The author finds, however, that this relation is considerably influenced by various factors, and, on the basis of a large number of experimental numbers given by various investigators, he formulates the relationship between boiling point and critical temperature as follows. With all substances having less than five atoms in the molecule, and having, also, low molecular weights, the ratio of boiling point to critical temperature has the mean value 0·666. The ratio varies, however, from 0·580 for the lower members of a homologous series to 0·700 for the highest members investigated.

T. H. P.

Calculation of Thermochemical Constants. V. Calculation of the Thermal Constants of Aromatic Substances. H. Stanley Redgrove (Chem. News, 1908, 98, 80. Compare this vol., ii, 564).—The author gives in tabular form a comparison of the molecular heats of combustion and formation as determined by Thomsen, and as calculated by himself for toluene, mesitylene, ψ-cumene, chlorobenzene, anisole, and phenol. The method of calculation does not necessitate any assumption concerning the constitution of benzene. The figures show that the various groups exhibit the same thermal behaviour in aromatic as in aliphatic compounds. P. H.

Free Energy Changes Attending the Formation of Certain Carbonates and Hydroxides. John Johnston (J. Amer. Chem. Soc., 1908, 30, 1357—1365. Compare this vol., ii, 358).—The increase of free energy attending the conversion of a hydroxide into the oxide and water vapour, and of a carbonate into the oxide and carbon dioxide, can be expressed by the equation $\Delta F = \Delta H + RT\ln p + IT$ ($\Delta H$ being the increase in total energy). Calculations from existing pressure data for the hydroxides and carbonates of magnesium, calcium, lithium, strontium, and barium give, in general, very concordant values for $I$, the thermodynamically undetermined constant,
The increase in free energy at $25^\circ$, accompanying the formation of these substances, and their dissociation pressures at $25^\circ$ have been calculated. The results show that the stability of the hydroxides and carbonates increases in the order magnesium, calcium, lithium, strontium, barium, sodium.

It is shown that neither Le Chatelier and de Forcrand's rule, $T=\Delta H/30$, nor Nernst's approximate formula for heterogeneous equilibria, $\log p = \Delta H/4.576T + 1.75\log T + C$, can lead to accurate results, except in special cases.

E. G.

**Hydrolysis as Illustrated by Heats of Neutralisation.** VICTOR H. VELEY (Trans. Faraday Soc., 1908, 4, 19—26. Compare Lundén, this vol., ii, 164).—The paper contains a summary of the available data as to the acid and basic dissociation constants of a number of weak bases and acids and the degree of hydrolysis of their salts, as determined by Bredig, Winkelblech, Walker, Lundén, and the author. The heats of neutralisation determined directly of these weak bases and acids are also given as far as available, as are the values calculated by Lundén and others by means of the van t'Hoff equation connecting heat development and displacement of equilibrium. The data appear to show that the higher the value for the heat of neutralisation the less is the degree of hydrolysis, and conversely.

G. S.

**Orthobaric Volumes in Relation to Pressure and Temperature.** EDWARD HAIGH (Phil. Mag., 1908, [vi], 16, 201—223); SYDNEY YOUNG (ibid., 222—223).—Haigh puts forward a dual equation to express the relation of the orthobaric volumes of liquid and saturated vapour to vapour pressure and temperature of ebullition. At the critical point, the dual equation reduces to the well-known van der Waals' form. The dual equation affords results which are in excellent accord with the experimental values in the cases of fluorobenzene, isopentane, benzene, and a number of other hydrocarbons. The small deviations observed with methyl and propyl alcohols, carbon tetrachloride, and stannic chloride are explainable as polymerisation effects and experimental errors.

With a liquid far removed from its critical point, a small experimental error in the volume is greatly magnified, and the spheres of action of the molecules may intersect. The theorem may be utilised to test the accepted values of the critical constants of a substance, for on combining them with the data of observations at temperatures below the critical point, the dual equation should hold good.

From the specific volumes of isopentane liquid and vapour at temperatures between $10^\circ$ and $120^\circ$, the critical volume of this substance is calculated to be 4.2686, whereas Young obtained the value 4.266 experimentally.

This agreement does not constitute an independent proof of the validity of the dual equation, since the value of the critical volume (4.266) was assumed for the purposes of the former proof. R. J. C.
Saturated Aqueous Solutions of Sparingly Soluble Salts. II. The Amounts Dissolved and their Alteration with Temperature. Friedrich Kohlrausch (Zeitsch. physikal. Chem., 1908, 64, 129—169. Compare Abstr., 1903, ii, 528).—The experimental material previously collected (loc. cit.) has been subjected to recalculation, with the result that some of the values for the solubility already communicated (Abstr., 1905, ii, 152) have undergone alteration. In this extension of the work, special attention has been paid to ascertaining the value of the equivalent conductivity which should be employed in calculating the solubility from the specific conductivity of the saturated solution. It is only in the case of salts with extremely low solubility that \( \lambda_\infty \) can safely be taken as the equivalent conductivity of the saturated solution. The correct value can, however, be ascertained on the basis of the rule that in dilute solutions \( \lambda \) changes almost proportionally with the square root of the concentration. For details of the way in which this rule is applied to the different salts, the original must be consulted. Another point to which attention has been paid in this extension of the work, is the evaluation of the solubility for temperatures other than 18°.

The following is a list of the salts for the solubility of which an appreciably different value has been found on recalculation; the number given after each salt represents the weight in milligrams present in a litre of the saturated solution at 18°: magnesium fluoride, 87; silver chloride, 1-34; silver iodate, 38-5; lead iodate, 17-8; barium chromate, 3-5; lead chromate, 0-1; barium oxalate \((\text{BaC}_2\text{O}_4 \cdot 2\text{H}_2\text{O})\), 85-1; barium oxalate \((\text{BaC}_2\text{O}_4 \cdot 3\frac{1}{2}\text{H}_2\text{O})\), 105. In addition, numbers are given for the following minerals: fluorite, 15-0; barytes, 2-6; celestine, 114-3.

For the values of the solubility at temperatures other than 18°, the original must be consulted. Of the salts examined, magnesium fluoride is the only one the solubility of which diminishes as the temperature rises.

J. C. P.

Studies of the Processes Operative in Solutions. VI. Hydrolysis, Hydrolation, and Hydronation as Determinants of the Properties of Aqueous Solutions. Henry E. Armstrong (Proc. Roy. Soc., 1908, 81, A, 80—95. Compare Abstr., 1907, ii, 848, 849, 850).—Water is regarded as a complex mixture of active and inactive molecules; the active components are monad hydrone \((\text{H}_2\text{O})\) molecules and hydrol-hydron (briefly hydronol or hydrol) molecules, \(\text{H}_2\text{O}\overset{\text{H}}{\underset{\text{OH}}{\downarrow}}\); the inactive molecules are a series of polyhydrones (formed by association unaccompanied by rearrangement) of the form \(\text{H}_2\text{O}:\text{OH}_2\), \(\text{H}_2\text{O}\overset{\text{OH}_2}{\underset{\text{OH}}{\downarrow}}\), &c.

When non-electrolytes of the type \(\text{RX}\) are dissolved in water, interaction takes place with the hydrol molecules present in the solvent, with the ultimate possible production of active complexes, \(\text{RX}\overset{\text{H}}{\underset{\text{OH}}{\downarrow}}\) inactive hydron complex, \(\text{RX}:\text{OH}_2\), and polymerides of the type \(\text{RX}:\text{XR}\).
When, on the other hand, substances which form conducting solutions are dissolved in water, not only does the compound become hydrolated with formation of complexes of the type
\[ RX\text{OH} < \text{H} \text{OH} \quad (a), \]
but its component groups also become distributed (re-arranged), forming complexes of the type
\[ \text{H}_2\text{O} < \text{R} \quad (b); \]
the latter process is a kind of hydrolysis, but the groups are only distributed and not set free. The occurrence of electrolysis in such solutions is dependent on influences which the composite molecules \((a \text{ and } b)\) exert reciprocally on one another whilst under the influence of the electric strain.

The above considerations are applied to the interpretation of the most various properties of aqueous solutions, such as electrolytic conductivity, hydrolysis, neutralisation of acids by alkalis, hydration, compressibility, and the so-called ionic properties of aqueous solutions. It is considered that the conductivity in concentrated solutions is conditioned mainly by molecules of the hydrolysed solute of type \(b\), whilst in dilute solutions it is due mainly to molecules of type \(a\). In general, the changes which take place in aqueous solution involve the interaction of the composite molecules above referred to; for example, the neutralisation of hydrochloric acid by sodium hydroxide may be represented by the equation:

\[ \text{HCl} < \text{H} \text{OH} + \text{NaOH} < \text{H} \text{OH} = \text{NaCl} + 3\text{H}_2\text{O}. \]

The considerable expansion attending such neutralisations cannot be adequately accounted for on the ionic theory, but on the present theory, is a simple consequence of the different modes of combination of the water before and after neutralisation. It is shown that when measurements are made with weight-normal solutions, the change of volume on neutralisation is greater for sodium than for potassium salts.

Hydration may be of two kinds, according as it involves hydrolation or hydronation. The effect of sugars in reducing the conductivity of electrolytes (compare No. X) is probably connected with the association of their oxygen atoms with hydroly. In hydriones, for example, NaCl·OH₂, the salt is rendered comparatively inactive, but, owing to the ethenoid linking, the associated water has probably a greater optical effect than ordinary water, the increase in refractive index which attains solution in water being thus accounted for.

G. S.

Studies of the Processes Operative in Solutions. VII. Relative Efficiencies of Acids as Deduced from their Conductivities and Hydrolytic Activities. Henry E. Armstrong and E. Wheeler (Proc. Roy. Soc., 1908, 81, A, 93—102).—The electrolytic and hydrolytic activities of hydrochloric, nitric, and sulphuric acids in various dilutions are contrasted, and the conclusion is drawn that the processes are altogether different in character. The hydrolytic activity was determined with sucrose in the usual way, and weight-normal solutions were employed.

When weight-molar solutions of the three acids are compared
nitric acid is least, and sulphuric acid most, active as hydrolyst, and to reduce the other acids to the same activity as nitric acid, 3 mols. of water have to be added to the hydrochloric acid solution and 7 mols. to the sulphuric acid solution. In 1/10 and 1/20 molar solution, hydrochloric and nitric acids are more nearly equal in activity, but sulphuric acid is much stronger than either, its strength not being reduced so much by dilution. The diminution of hydrolytic activity on dilution from molar to 1/10 molar solution for the monobasic acids is not proportional to the dilution, but about 1.5 times as great.

For solutions of the three acids of equal conducting power, the hydrolytic activities at 25° are in the ratio $HNO_3:HCl:H_2SO_4 = 100:107:180$ when the activity of weight-normal nitric acid = 100.

The molecular conductivities of the various solutions are also given in tabular form.

G. S.

Studies of the Processes Operative in Solutions. VIII. The Influence of Salts on Hydrolysis and the Determination of Hydration Values. Henry E. Armstrong and D. Crothers (Proc. Roy. Soc., 1908, 81, 4, 102—112. Compare Senter, Trans., 1907, 91, 460; Proc., 1908, 24, 89).—It has been shown in a previous paper (No. IV, loc. cit.) that the "average degree of hydration" of certain alkali chlorides and nitrates is considerably greater when determined from hydrolysis experiments with sucrose in the presence of the corresponding acids than when methyl acetate is used as hydrolyte, and that the nitrates give lower values than the chlorides, especially with methyl acetate. On the preliminary assumption that the results obtained with sucrose are the true hydration values, and that the smaller values observed with methyl acetate are due to combination of salt and ester, the average amount of each salt combined with the ester is calculated. This explanation of the different effect on the two hydrolytes is not, however, regarded as satisfactory.

In order to obtain further information on this point, the relative influence of nitrates and chlorides on the molecular solution volume of methyl acetate, and on the electrical conductivities of the respective acids in the presence and absence of methyl acetate, has been measured, but in no case is the difference so great as for the influence on the hydrolytic activity. For comparative purposes, the effect of sucrose, dextrose, and raffinose on the conductivity of the salts was also measured.

It is suggested that the differences are best accounted for on the basis of the considerations advanced in communication VI. The "hydration values" will vary from case to case, and the highest values will be obtained by using hydrolytes and hydrolysts which form relatively stable hydrolys in solution, as these will be less affected by the introduction of salts. Methyl acetate holds hydrol but weakly, and is therefore easily rendered inactive by salts.

The effect of methyl acetate in diminishing the conductivity of electrolytes is probably mainly mechanical, but the sugars appear to exercise a direct dehydrolating influence as well as a mechanical effect.

G. S.
Studies of the Processes Operative in Solution. IX. Determination of Optical Rotatory Power. ROBERT J. CALDWELL and R. WHYMPER (Proc. Roy. Soc., 1908, 81, A, 112—117).—A modified polarimeter provided with a spectroscopic eyepiece is described and figured. A sodium lamp for obtaining a very bright flame is described, but the Bastian mercury lamp was found to possess considerable advantages as a source of illumination, the green line (546.1 μμ) being very bright, pure, and of constant intensity.

The effect on rotatory power, the volume change, and (in the case of salts) the change of conductivity produced by adding sucrose to each of a large number of electrolytes and non-electrolytes in weight-molar solution, have been determined.

The influence of non-electrolytes on the rotatory power is slight; the greatest effect is exerted by acetaldehyde (an increase) and by chloral hydrate (a decrease). Electrolytes all diminish the rotation slightly, and the effect increases in the order nitrates, chlorides, sulphates, alkali hydroxides; it is ascribed mainly to combination between electrolyte and sugar.

The molecular conductivity of the most various salts (in molar solution) is reduced to the extent of 43—51% by the addition of 1 mol. of sucrose. The diminution is partly due to combination between sugar and salt, but mainly to the reduction of the salt to an inactive state, probably by withdrawal of hydrol (compare No. VI). On the basis of certain assumptions, an attempt has been made to ascertain the extent to which sugar enters into combination with certain salts. The order of the effect of salts on the rotatory power is in the main the same as that in which their conductivity is affected by the addition of sugar.

The admixture of sugar with salts in solution is usually attended with considerable expansion, but in the case of non-electrolytes there is very little effect.

Calculation of the Diffusion Constants of Non-electrolytes in Solution. MAX VON WOGAU (Ber. deut. physikal. Ges., 1908, 6, 542—545).—By means of the author’s formula (Abstr., 1907, ii, 606) for the diffusion constant of a non-dissociated substance in dilute solution, values are obtained for aqueous solutions in approximate agreement with the experimental values. The values for the diffusion constants of bromine and iodine in benzene and carbon disulphide do not agree so well with the observed values, and this is attributed to the relatively larger size of the solvent molecules.

Theory of Capillarity. E. T. WHITTAKER (Proc. Roy. Soc., 1908, 81, A, 21—25).—The surface energy, $\lambda$, of a liquid is related to the surface tension, $\gamma$, by the equation: $\gamma = \lambda + T \frac{d\gamma}{dT}$, where $T$ denotes absolute temperature. By means of this equation, the surface energy
for a few non-associating liquids has been calculated from the values of the surface tension at different temperatures observed by Ramsay and Shields, and it is then shown that the surface energy of a liquid in contact with its own vapour at any temperature is proportional to the product of the "internal latent heat" and the absolute temperature. The "internal latent heat" is that part of the observed latent heat which is used up in increasing the internal energy of a substance as it passes from the state of liquid to that of vapour.

G. S.

Viscosity of Colloidal Silver Solutions. H. W. Woudstra (Zeitsch. physikal. Chem., 1908, 63, 619—622. Compare this vol., ii, 160).—The viscosity of a given colloidal silver solution gradually diminishes with time. When solutions containing different amounts of silver are compared, it is found that the viscosity increases with the concentration. The viscosity of a colloidal silver solution is lowered by electrolytes, an observation which should be contrasted with the action of electrolytes on gelatin solutions (see, for instance, Levites, this vol., ii, 161). J. C. P.

The "Negative" Viscosity of Aqueous Solutions. William White Taylor and T. W. Moore (Proc. Roy. Soc. Edin., 1908, 27, 461—471. Compare Taylor and Ranken, Trans. Roy. Soc. Edin., 1906, 45, 397; Jones and Veazey, Abstr., 1907, ii, 438; Getman, ibid., ii, 744).—In order to test the theory that the cations, in opposition to undissociated molecules and anions, tend to diminish the viscosity of water, and that the activity of the cations increases in general with the atomic volume, the authors have measured the viscosity of aqueous solutions of tetramethylammonium iodide, tetraethylammonium chloride and bromide, and of tetrapropylammonium chloride and iodide at 25° and 35°.

The viscosity increases with increasing volume of the cation, and in no case is there the slightest approach to "negative" viscosity. The influence of the anion on the viscosity is very small. The values for tetraethylammonium chloride and bromide are much more nearly equal than the viscosities of solutions of hydrochloric and hydrobromic acids, of the potassium salts, or of the ammonium salts. The viscosity of salt solutions cannot therefore be regarded as simply an additive property.

The density of tetrapropylammonium chloride solutions decreases with increasing concentration, the diminution being more marked at 35° than at 25°. H. M. D.

Theory of Adsorption. T. Brailsford Robertson (Zeitsch. Chem. Ind. Kolloide, 1908, 3, 49—76).—A theoretical paper of a highly controversial character, in which the view is advocated that the phenomena of adsorption are in reality chemical equilibria, in which capillary condensation plays at most a very unimportant part. T. E.
Adsorption Phenomena of Inorganic Salts. Hans E. Wohlers (Zeitsch. anorg. Chem., 1908, 59, 203—212).—When barium sulphate is precipitated in a strong solution of potassium permanganate, the precipitate carries down some of the permanganate, as is shown by the fact that after boiling with hydrochloric acid to remove manganese dioxide the precipitate is still rose-red. The amount of permanganate adsorbed is too small to be estimated gravimetrically. The adsorbed permanganate does not react with hydrogen peroxide or sulphurous acid, nor does adsorbed ferric chloride react with potassium ferrocyanide. On heating the precipitates, however, adsorbed substances undergo chemical changes; thus the pink barium sulphate becomes brown on heating, owing to the formation of manganese peroxide, and adsorbed red cobalt sulphate becomes blue on heating.

Strontium sulphate also adsorbs potassium permanganate, but calcium and lead sulphates and silver chloride do not do so to any appreciable extent.

The absence of chemical reactivity on the part of adsorbed substances might be accounted for on physical lines as being due to a great diminution of solubility, but the author considers it more probable that precipitate and adsorbed substance become chemically combined.

G. S.

Dissociation of a Compound in a State of Equilibrium, and a Thermodynamic Relation Necessary to the Validity of the Law of Constant Proportions. Rudolf Ruer (Zeitsch. physikal. Chem., 1908, 64, 357—373).—It has been shown (Abstr., 1907, ii, 433) that a compound AB fusing to a homogeneous liquid, and capable of dissolving both A and B, must be dissociated when in a state of equilibrium. The conditions of such equilibria in the solid, liquid, and gaseous state are now discussed on the basis of the thermodynamic potential. It is shown on theoretical grounds that two solid or two liquid phases must always possess a certain degree of miscibility, although this miscibility may be very small. C. H. D.

The Unimolecular Course of the Decomposition of Ammonia by the Silent Discharge. Robert Pohl (Zeitsch. Elektrochem., 1908, 14, 439; Max Le Blanc, ibid., 507).—A claim for priority against Le Blanc and Davies (this vol., ii, 653) and a reply by Le Blanc, who points out that, whereas Pohl found the decomposition to be unimolecular, he and Davies arrived at the opposite result.

T. E.

Position of the Ammonia Equilibrium. Fritz Haber and Robert Le Rossignol (Zeitsch. Elektrochem., 1908, 14, 513—514).—In consequence of Jost’s criticism (this vol., ii, 761), the authors have made measurements with thermocouples both inside and outside their quartz tube, which show that the difference of temperature is at most 3°. They maintain the accuracy of their results (Abstr., 1907, ii, 454; this vol., ii, 362).

T. E.
Temperature of Dissociation of Ammonia and of Carbon Monoxide. HERMAN C. WOLTERECK (Compt. rend., 1908, 147, 460—461).—Pure dry ammonia was passed through a heated tube of Jena glass. The first signs of dissociation were observed at 620°; above 630° an explosive mixture of gases was produced. Decomposition occurred at a considerably lower temperature in presence of traces of organic matter or water vapour. When passed over heated iron gauze, dissociation commenced at 320°, whilst in presence of ferric oxide no decomposition took place below 420°.

Carbon monoxide dissociates at 570—580°, but in presence of traces of moisture no decomposition occurs even at higher temperatures.

W. O. W.

Theory of Colloids. EDUARD JORDIS (Zeitsch. Chem. Ind. Kolloide, 1908, 3, 13—26. Compare this vol., ii, 675).—The suspension theory, the theory of electric charges, the adsorption theory, and the partition theory are criticised, in the sense that none of them is applicable to all colloids, and that they all neglect chemical changes in the colloid itself and reactions between it and substances in solution.

T. E.

Modification of Wolfgang Ostwald's System of Colloids. P. P. VON WEIMARN (Zeitsch. Chem. Ind. Kolloide, 1908, 3, 26—27).—In dispersed systems the dispersion may be molecular (as in true solutions of solids or liquids) or the molecules may be aggregated to minute crystals or drops (as in suspensions or emulsions). Between these extremes there are molecular dispersions of compounds of high molecular weight, and then "suspensoids" and "emulsoids" (colloidal solutions in which the colloid is solid or liquid). True solutions are called dispersions; colloidal solutions, suspensions, and emulsions are called dispersoids. The word colloid is avoided altogether.

T. E.

System of Colloids. WOLFGANG OSTWALD (Zeitsch. Chem. Ind. Kolloide, 1908, 3, 28—30).—The nature of gelatin and agar-agar solutions is discussed. The author gives reasons for supposing them to contain two liquid phases; the gelatinous precipitates of inorganic salts obtained by von Weimarn (this vol., ii, 90) are regarded as emulsions of two different solutions, which are prevented from mixing by solid membranes of the salt. A high molecular weight is not a necessary condition for the existence of a substance in the gelatinous form, which appears rather to depend on the physical conditions than on the chemical nature of the substance.

T. E.

Classification of Solutions of Colouring Matters. H. FREUNDLICH and W. NEUMANN (Zeitsch. Chem. Ind. Kolloide, 1908, 3, 80—83).—The solutions of colouring matters are true solutions, semi-colloidal and colloidal. They are classified by their diffusion through parchment paper and by their ultra-microscopic behaviour. The colloidal solutions belong to two classes, the suspension colloids, the freezing point and surface tension of which are practically the same as those of pure water, and the emulsion colloids, the properties of which differ from those of water.
Measurements of the surface tension of aqueous and alcoholic solutions of several colouring matters are given. They all form true solutions in alcohol, and the surface tension is slightly increased. Among the aqueous solutions, rhodamine (true solution), crystal-violet (semi-colloidal), and night-blue (colloidal) diminish the surface tension, whereas the other colouring matters leave it practically unchanged.

T. E.

Effect of Electrolytes on the Viscosity of Colloids. GOKUN (Zeitsch. Chem. Ind. Kolloide, 1908, 3, 84—88).—The effect of ammonium nitrate on the viscosity of solutions of gelatin is studied. The viscosity of a pure gelatin solution (0·28%) increases with time, increasing by one-half in 115 hours. The addition of ammonium nitrate diminishes the rate of increase, so that when the concentration of the salt is from 1·5N to 2N, the viscosity remains almost constant; with greater concentrations, the viscosity diminishes with the time instead of increasing. The viscosity depends on the mechanical treatment to which the solution has been subjected; repeated passage of the same solution through a capillary tube gives different results; also, the viscosity measured by passing the solution through a narrow tube under high pressure is not the same as that observed with a wider tube and lower pressure. This points to the existence of a structure in the solutions.

T. E.

Nature of Precipitated Colloids. HARRY W. FOOTE (J. Amer. Chem. Soc., 1908, 30, 1388—1394).—Experiments are described which afford evidence that precipitated ferric and aluminium hydroxides may be regarded as solutions of water in the oxides or lower hydroxides, that is, solutions of liquids in solids.

Samples of the precipitated hydroxides were left in the air for several days at the temperature at which the experiments were to be carried out. The composition of the material was then determined by ignition, and a weighed quantity was put into a porcelain crucible, which was placed on a raised triangle in a large weighing bottle containing a little water. The bottle was carefully sealed and left for eighteen to forty-eight hours. The crucible was then quickly removed, and weighed in order to determine the change of weight. The experiments were made at 25° and 45°. The composition of the product at any point could be calculated from the known composition of the original material.

All the moist precipitates lost weight slightly over water, but, after being dried in the air to a certain point, they began to gain weight when placed over water. This was due to the fact that their vapour pressures had fallen below that of the water, showing that the water phase had just disappeared. The composition at the point at which the gain in weight first occurred was approximately that of the saturated hydrate free from mechanically-contained water. The averages of a large number of determinations gave the following as the composition of the saturated solutions of water in the oxides. Ferric hydroxide at 25°: Fe₂O₃, 47·72—47·79%; at 45°, 54·53—56·74%; aluminium hydroxide at 25°: Al₂O₃, 49·52—51·17%; at 45°, 52·57—53·82%.
Similar experiments were made with zirconium hydroxide, and the composition of the saturated solutions at 25° were found to be: ZrO₂, 32·02—32·33%.

E. G.

Coagulation of Colloidal Solutions in Galvanic Cells. Wilhelm Biltz (Zeitsch. Elektrochem., 1908, 14, 567—571).—Two metals are immersed in solutions of colloidal ferric hydroxide, gold, or antimony sulphide, purified by dialysis, and the cell so formed short circuited. In all cases the colloid is coagulated, the precipitate forming partly on one of the metals and partly in the solution near it. The more noble metals alone have no action; the less noble ones have a small action. Ferric hydroxide is precipitated on or near the more noble metal of the couple; gold and antimony sulphide go to the less noble metal. The phenomenon is not due to the current alone; the E. M. F. of the zinc copper element, for example, is under 1 volt, and this voltage applied to platinum electrodes in a gold hydrosol produces no precipitate. On the other hand, the quantity of zinc hydroxide which is formed from the zinc electrode is comparable in weight with the quantity of gold precipitated, and it is found almost entirely in the precipitate. The action therefore appears to be mainly due to the action of bivalent ions formed from the metals in the short circuited cells.

T. E.

Agglutination and Coagulation. Svante Arrhenius (J. Amer. Chem. Soc., 1908, 30, 1382—1388).—The work described was carried out with the object of obtaining evidence as to the nature of agglutination. Two views have been advanced, one, the colloidal theory, according to which the suspended particles (bacteria or blood corpuscles) collect together and subside under the influence of electrolytes or agglutinins, and the other, first proposed by Duclaux, that agglutination depends on the coagulation of some substances in the cells which causes the cells to cling together and subside.

Experiments have been carried out on the precipitation and agglutination of blood corpuscles by means of various salts. Ox-blood corpuscles were suspended in solution of sodium chloride (0·9%) or sucrose (7%), the emulsions containing 4, 1, and 0·25% of corpuscles. To 5 c.c. of such solutions, varying quantities of the salt solutions were added. The minimum quantity of each salt required for precipitation and for agglutination was noted. The results are tabulated, and show that, with certain exceptions, there is a well-marked relation between the precipitating and agglutinating powers of each salt. Salts which give a maximum precipitation at a certain concentration also give a maximum agglutination at a certain concentration, but if a maximum does not appear in the one case, it also fails in the other. It is therefore concluded that, as Duclaux has suggested, agglutination depends on a precipitation, and that this precipitation is due to a chemical reaction between the metal ions and the proteins in the corpuscles. In general, both precipitation and agglutination in sugar solutions require less quantities of the added salt than in sodium chloride solutions.

Many substances cause agglutination as well as haemolysis of the
blood corpuscles, and among these may be mentioned the nitrates of silver and lead, mercuric chloride, and the acids (compare this vol., ii, 708). The hæmolytic action does not run parallel with the agglutinating action.

The quantity of a salt required to be added for the precipitation of a blood solution is proportional to the concentration of the latter. Since the quantity of the salt required increases more slowly than the concentration, it is evident that there exists a chemical equilibrium between the two salt-like products derived from the blood solution and the ions of the precipitating salt. All the evidence obtained in this investigation is in favour of the physico-chemical theory, according to which the observed phenomena are due to ordinary chemical processes.

E. G. Bechhold (Zeitsch. physikal. Chem., 1908, 64, 328—343).—The author’s gelatin “ultra-filters” (this vol., ii, 24), for the separation of colloids from the solvent, vary in fineness according to the concentration of the gelatin. Some of them are too fine to allow of the determination of the size of their pores by ultra-microscopic examination of the colloids retained by them. By considering the pores as capillary tubes or as slots, their dimensions can be arrived at by measuring the pressure required to force air through them when immersed in water. This method was controlled by tests with a filter-paper which retains ox-blood corpuscles (diam. 7—8µ), for which the air-pressure method gave an average value of 1·5µ, and with Chamberland porcelain filters, which retain cocci (diam. 1µ), and where the method gave as a result 0·3µ. The same method provides a test for the uniformity in size of the pores. Ultra-filters may be tested in this way, and by the rate of passage of water.

Tests with ultra-filters indicate that the smallest particles of hæmoglobin have one-sixth the diameter of collargol particles, and that the smallest particles of litmus in alkaline solution, or of soap solution, have less than one-half the diameter of hæmoglobin particles.

C. H. D.
allotropic modifications in different proportions, the several solutions being separated by limiting surfaces in which surface-tension forces play an important part. At one and the same temperature, liquid sulphur may contain solutions in which these modifications are present in different proportions, this being determined by the previous physical treatment of the sulphur.

H. M. D.

**Velocity of Reaction.** Johannes J. van Laar (Chem. Weekblad, 1908, 5, 698—705).—A theoretical paper, in which the theory of reaction velocity is criticised, and a new thermodynamic theory put forward.

A. J. W.

**Temperature-coefficient of the Velocity of Chemical Reactions.** I. Max Trautz and Karl Theodor Volkmann (Zeitsch. physikal. Chem., 1908, 64, 53—88).—The velocity of saponification of eight esters in aqueous solution has been determined over a wide range of temperature. The temperature-coefficient of the velocity rises to a maximum between 10° and 20° in all cases, and thereafter falls off. At 60°, the value of the temperature-coefficient is frequently as low as 1·4, so that the difference in magnitude as compared with the temperature-coefficient of a photochemical reaction is not so marked as has usually been assumed. The existence of a maximum temperature-coefficient between 10° and 20° is probably connected with an irregularity which occurs in the viscosity of water in that region. The observed variation of the temperature-coefficient with the temperature may in fact be reproduced by a formula into which the viscosity of water enters.

The authors' experiments tend to show that the mass action law is strictly applicable to the saponification of esters only when the concentration is less than $\frac{N}{75}$.

The paper contains an extensive list of references to earlier papers on the temperature-coefficient of reaction velocity, and this earlier work is subjected to a critical review.

A. J. W.

—Polemical. A reply to Cohen and Strengers (preceding abstract).

A. J. W.

**Effect of Ferric Salts on the Rate of Oxidation of Ferrous Salts and on the Catalytic Action of the Latter.** W. F. Green (J. Physical Chem., 1908, 12, 389—397).—The influence of ferric salts on the rate of oxidation of ferrous salts by chloric acid and by oxygen, and on the rate of oxidation of iodides
by chlionic and bromic acids in the presence of ferrous salts, has been investigated. It is found that ferric salts are without influence on the rate of oxidation of ferrous salts by chloric acid and by oxygen. The liberation of iodine from iodides by chlionic and bromic acids is accelerated by both ferrous and ferric salts, the rate depending merely on the amount of iron present, and not on its state of oxidation. In solutions containing ferrous and ferric salts, the effects of the two are additive.

H. M. D.

Reaction between Potassium Ferricyanide and Potassium Iodide. Gerhard Just (Zeitsch. physikal. Chem., 1908, 63, 513—578. Compare Donnan and Le Rossignol, Trans., 1903, 83, 703).—This reaction may be conceived as involving two stages:

(1) FeCy₆⁺ + ⊕ = FeCy₆⁻⁺ ; (2) I⁻⁺ + ⊕ = I⁻. The velocity of the latter process is practically that of an instantaneous reaction, as shown by Brunner (Abstr., 1907, ii, 223). Process (1), however, is not to be regarded as an instantaneous reaction, as shown by a study of the polarisation at an electrode immersed in a solution containing both ferro- and ferri-cyanide. When the electrode consists of platinum, it is practically unpolarisable, but this is not at all the case when the electrode consists of gold or silver. Hence process (1) is not instantaneous; it is very markedly accelerated by platinum, the acceleration being apparently connected with an oxidation and reduction of the metal. The accelerating effect of platinum on the rate of reaction between potassium ferricyanide and iodide can be demonstrated directly. From the fact that process (1) is not instantaneous, the author draws the conclusion that the difference between the FeCy₆⁻⁺ and FeCy₆⁺⁺ groups cannot be one of charge alone; they must have a different constitution.

The results of quantitative experiments made on the rate of reaction between ferricyanide and iodide confirm those recorded by Donnan and Le Rossignol (loc. cit.), but the interpretation of the results is different. The application of the Noyes-van't Hoff formula to the author's measurements shows that the reaction is of the first order in regard to the ferricyanide, and of the second order in regard to the iodide. Altogether, therefore, the reaction between potassium ferricyanide and iodide is one of the third order, not of the fifth, as held by Donnan and Le Rossignol.

It appears fairly certain that it is the undissociated ferricyanide which takes part in the reaction, for the velocity is very markedly increased by the addition of indifferent potassium salts. In what form the iodide takes part, whether as ion or as undissociated salt, it is not possible to determine, although it is considered most probable that the ions are actively concerned.

A complete kinetic equation has not been constructed, but attention is drawn to the following observations, which would have to be considered in working out such an equation. The reaction between ferricyanide and iodide is notably retarded by ferrocyanide, but not by iodine; it is accelerated by both cyanide and fluoride ions; it is retarded by hydroxyl ions, but accelerated by hydrogen ions. Indications were also obtained that an intermediate product plays some part in the reaction.

J. V. E.

Laboratory Apparatus. W. Heber Green (Chem. News, 1908, 98, 49—50).—Determination of Density.—The maximum error liable to occur in determining the density of water by means of a pear-shaped specific gravity bottle is found to be 0.00002. To obtain this accuracy, the bottle, which can only be used for temperatures above that of the surrounding atmosphere, is filled with the solution and immersed to the neck in a thermostat constant within 0.04°; after ten to fifteen minutes, the expansion of the solution through the perforated stopper is complete; the bottle is then dried and cooled for fifteen minutes, and finally weighed, the density being calculated from the formula 

\[ \rho = \frac{M}{W}(1 + 0.0012/d - 0.0012), \]

in which \( W \) and \( M \) are the apparent weights of water and solution respectively required to fill the bottle. The formula is only approximate, and disregards variations of atmospheric pressure which are often sufficient to nullify the correction. The most serious fault of the instrument is the fact that wear on the ground surfaces of the stopper and neck diminishes the capacity of the pyknometer.

A Sensitive Form of Thermo-regulator.—The thermostat is of the ordinary type, and consists of a toluene bulb of about 20 c.c. capacity attached to a U-tube containing mercury, which is connected by a capillary tube to the by-pass, the novelty of which is that the gas inlet-tube is slightly opened out instead of being left square. As soon as the mercury reaches the funnel-shaped opening of this tube, its capillarity tends to force it down again and so admit the gas supply. The temperature was found to remain constant within 0.01° for several weeks, provided the bath was efficiently stirred.

A Sensitive Temperature-compensated Barometer.—A modification of a Huyghens glycerol-mercury barometer in which the former liquid is replaced by paraffin oil, b. p. 230°. The vapour pressure of this oil varies with temperature at such a rate as almost exactly to neutralise the effects of the accompanying expansion of mercury for the particular dimensions of tubes used. The rise and fall of the liquid for a variation of one-hundredth of an inch in the atmospheric pressure is sufficiently large to be seen at some distance.

P. H.

Erper's Gas Generating Apparatus. L. Gutmann (Zeitsch. angew. Chem., 1908, 21, 1798).—The apparatus consists of a pear-shaped funnel for holding marble or iron sulphide, which is fitted into the neck of a bottle containing acid; the lower end of the bottle is connected by a side-tube and a tap, \( A \), to a raised reservoir. The top of the funnel is fitted with a tap, \( B \), and a delivery tube; near the lower end of the funnel is a side-tube through which the spent acid may be withdrawn after closing the delivery tube and opening the tap \( B \). When re-charging with solid, the tap \( A \) is closed.

P. H.
Modified Form of Saint-Claire Deville's Apparatus for Continuous Production of Gases. Victor Grignard (Bull. Soc. chim., 1908, [iv], 3, 890—892).—The modification is devised to overcome the disadvantages of the ordinary Saint-Claire Deville apparatus, namely, the difficulty of using up the whole of the acid and the clogging of the rubber tubing by crystals deposited from the saturated solutions formed when the apparatus has been long in action.

For this purpose, the ordinary rubber tube connexion is prolonged upwards at an obtuse angle inside the bottle containing the acid, by a glass tube reaching to a level slightly below that of the liquid, so that it is always the strongest acid which comes into action first, and the denser liquid remains at the bottom of the bottle. Continuity of action can be secured by having the side aperture of the acid bottle halfway up the latter, and making the connexion between the two bottles by two glass tubes parallel to each other and prolonged into the acid bottle at obtuse angles to the horizontal with their arms turned in opposite directions. To permit of this arrangement, the bottle containing the solid is raised on a small block, so that its side aperture is opposite that of the acid bottle. In this way by the action of gravity a continuous flow of acid through the solid to be acted on is maintained.

Simple Regulator for High Pressure Gas. Robert Le Rossignol (Chem. Zeit., 1908, 32, 820).—By making the cone angle of an ordinary screw-down tap very small (4°), it is possible to obtain gas from a cylinder at any required pressure in a simple manner. A slow, steady current of oxygen, as used for combustion purposes, may be obtained directly from a cylinder of the compressed gas by using such a form of tap.

New Method for Calibrating Capillary Tubes. Bohdan von Szyszkowski (Zeitsch. physikal. Chem., 1904, 64, 201—214).—The process and apparatus are practically the same as those employed in the measurement of surface tension. The heights to which water and dilute solutions of isoobutyric acid rise in two capillary tubes of about the same bore are accurately measured, and the exact radius of the tubes at various points is thus determined. The application of the method is illustrated by full data for two tubes which the author has examined.

Improved Pipette. Woithe (Chem. Zentr., 1908, ii, 1; from Arbff. Kais. Gesundh-Amr., 1908, 28, 401—404).—This suction arrangement for use with very poisonous or infectious materials consists of a small syringe of about 5 to 7 ccm. capacity, connected to a pipette by a U-tube, and held by a spring-clip.

Automatic Syphon Pipette. Herbert S. Bailey (J. Amer. Chem. Soc., 1908, 30, 1508—1509).—A description and diagram are given of an apparatus for delivering approximately constant quantities of a reagent, such as the sulphuric acid for the Babcock milk test or
the Kjeldahl nitrogen estimation. For details, the original must be consulted.

Steam Inlet-tube. H. Stoltzenberg (Chem. Zeit., 1908, 32, 770).—Instead of the ordinary open inlet-tube used for steam distillation purposes, a tube is described which is closed at the lower end, the steam being allowed to enter the liquid from a number of short, horizontally-curved side-tubes placed near the end. By this means the distillation flask may be used in an upright position; bumping is avoided because the liquid is caused to rotate rapidly by the issuing steam, and the process of distillation is considerably hastened.

J. V. E.

New Safety Valve. H. Stoltzenberg (Chem. Zeit., 1908, 32, 832).—A safety valve is described for use when gases are to be absorbed in liquids, such as carbon dioxide in potash solution. It will be seen from the figure, that the gas after entering \( a \), passes between the open ground-glass joint into the the outer vessel \( b \), and then through \( c \) to the potash solution. Should the absorption be so rapid as to cause the potash solution to flow back, the small inner flask is lifted up and closes the joint connecting \( a \) with \( b \).

J. V. E.

Use of Electrical Heating in Fractional Distillation. Theodore W. Richards and J. Howard Mathews (J Amer. Chem. Soc., 1908, 30, 1282—1284; Zeitsch. physikal. Chem., 1908, 64, 120—123).—In determining the latent heat of vaporisation of certain substances by a modification of Kahlenberg's method, it was observed that each organic liquid boiled much more constantly when heated electrically by the platinum coil immersed in it than when distilled in the ordinary way. A special form of apparatus has therefore been devised for use in fractionating organic liquids.

At the bottom of an ordinary stout distilling flask, a depression is blown of about the same diameter as the neck of the flask, and into this is placed a coil consisting of about 40 cm. of platinum wire with a resistance of about 0.7 ohm. A current of 10—15 amperes is led to the resistance coil from above by heavy copper wires of 2.5—3.0 mm. diameter enclosed in glass tubes, into the ends of which the ends of the platinum wire are sealed, contact being made by a drop of mercury.

Since the bubbles of vapour arise only from the small area of the resistance coil, ebullition proceeds quietly and without any bumping. The method is especially applicable to fractional distillation under reduced pressure; it obviates superheating, and effects a much more rapid and complete separation than the ordinary method of distillation.

E. G.
Receiver for Vacuum Fractional Distillation. J. Freundlich (Chem. Zeit., 1908, 32, 820).—An arrangement is described for collecting fractions in a vacuum without interrupting the process of distillation, the end of the condenser tube communicating by means of taps and short side-arms with two glass cylinders, the upper ends of which communicate with the exhaust tube by means of taps. J. V. E.

Apparatus for the Rapid Distillation of Mercury. Fortunato Florio (Nuovo Cim., 1908, [v], 16, 93—96).—An apparatus is figured and described, by which 2·5 kilos. of mercury can be distilled per hour. G. B.

Inorganic Chemistry.

A New Method for the Preparation of Pure Hydrogen. Mauricheau-Beaupré (Compt. rend., 1908, 147, 310—311).—Aluminium filings are mixed with a small quantity of mercuric chloride and potassium cyanide in powder. The product, to which the name “hydrogenite” is given, has D = 1·42. It can be preserved indefinitely if kept in a dry atmosphere, but when treated with water it becomes oxidised, with development of heat and liberation of pure hydrogen. One kilogram of the powder yields 1300 litres of hydrogen at 15° and 760 mm. To obtain the best yield, the action of the water must be regulated so as to maintain the temperature at about 70°, and a large excess of water should be avoided. W. O. W.

Preparation of Hydrogen Peroxide. C. A. F. Kahlbaum (D.R.-P. 197023).—Hydrogen peroxide can be prepared from its elements, or from a mixture of steam and these elements, or even from steam alone, when these gases are passed through a source of heat with a velocity of not less than one metre per second. The source of heat may be an electric arc, a spark discharge, or a flame of burning hydrogen, and the gases may be kept stationary while the heating apparatus is rotated. On condensing the steam, the hydrogen peroxide is obtained in the form of an aqueous solution. G. T. M.

Production of Hydrogen Peroxide from Aluminium and Zinc. Howard T. Barnes and G. W. Shearer (J. Physical Chem., 1908, 12, 468).—The statement made previously (this vol., ii, 344), that zinc in contact with water containing air or oxygen does not produce hydrogen peroxide, is contradicted by later observations. The difference between the behaviour of zinc and aluminium is traced to the fact that hydrogen peroxide is decomposed fairly rapidly in contact with zinc, but only slowly, if at all, in contact with aluminium. This is probably due to the difference in the extent to which the covering surface films protect the hydrogen peroxide from the action of the metals.
Copper, platinum, and iron in similar circumstances do not yield hydrogen peroxide.

Preparation of Perhydroxide Bases and their Salts. Richard Wolffenstein (D.R.P. 196369).—Sodium perhydroxide, NaOOH, is precipitated by adding 30% hydrogen peroxide to alcoholic sodium hydroxide or ethoxide; it is a strongly basic substance, and, when saturated with carbon dioxide, forms sodium hydrogen percarbonate, NaHCO₃. This compound is more stable than the product obtained by Tafel from sodium peroxide and alcohol (Abstr., 1894, ii, 448).

Sulphur Anion and Complex Sulphur Anions. Joseph Knox (Trans. Faraday Soc., 1908, 4, 29—49).—Many of the result given in the present paper have already been published (Abstr., 1906, ii, 608). The predominant complex in the solution of mercuric sulphide in sodium sulphide is Na₂HgS₂, but, when a solution saturated with both sulphides is concentrated over sulphuric acid, a double sulphide of mercury and sodium, 2Na₂S₅HgS₃H₂O, separates in yellow crystals.

The solubility of mercuric sulphide (black and red) in potassium sulphide solutions is somewhat greater than in sodium sulphide; the solubility in equivalent dilute solutions of barium and sodium sulphide is practically equal. The solubility of mercuric sulphide in sodium disulphide, Na₂S₂, is about half that in the normal sulphide, and in this case, also, the solubility is increased by the addition of sodium hydroxide. From the results of E.M.F. measurements, it is probable that the complex anion present in greatest amount is HgS₂⁻ in this case also.

The solubility product \( S = [\text{Hg}^{II}] [\text{S}^\text{V}] \) only remains constant for different ionic concentrations when it is assumed that the hydrolysis of sodium sulphide in dilute (0-05 molar) solution is practically complete. Küster and Heberlein (Abstr., 1905, ii, 156), however, found for the same solution a value less than 90% by a method depending on the decomposition of diacetonylacetone. The author has repeated these measurements, and finds a greater degree of hydrolysis than Küster, a result which is confirmed by conductivity measurements.

The solubility products of certain sulphides have been determined by E.M.F. measurements with rods of the respective metals dipping in a solution of sodium sulphide. The results at 25°C are as follows: \( [\text{Ag}^+][\text{S}^-] = 3.9 \times 10^{-50} \); \( [\text{Pb}^{II}][\text{S}^-] = 2.6 \times 10^{-15} \), and \( [\text{Cu}^{II}][\text{S}^-] = 1.2 \times 10^{-42} \).

Thiozonides. Sulphur and its Cyclic Compounds. Hugo Erdmann (Annalen, 1908, 362, 133—173).—Hoffmann and Rothe have shown (Abstr., 1906, ii, 279) that molten sulphur cooled to 160°C separates into two distinct liquid layers. The new modification of sulphur, which according to Smith and Holmes (Abstr., 1902, ii, 650) must be represented by \( S_x \), is shown to be \( S_3 \); in fact, this highly reactive, labile, dark-coloured form of sulphur is the analogue of
ozone, and is consequently named *thiozone*. As it would be more difficult to isolate thiozone in a pure state than ozone, it is best identified by its action on organic compounds. Ozone acts on unsaturated compounds, yielding ozonides or polyozonides (compare Harries, Abstr., 1906, i, 225); similarly, when unsaturated compounds are heated with sulphur at 160°, thiozonides or polythiozonides are formed: \[ \text{CR}_1\text{R}_2: \text{CR}_3\text{R}_4 + \text{S}:\text{S} \rightarrow \text{CR}_1\text{R}_2: \text{S} + \text{CR}_3\text{R}_4: \text{S}. \]

**Terpene Derivatives.**—Linalyl acetate is practically unattacked by sulphur at 150°, but at 160° the two substances interact energetically, yielding a *thiozonide*,

\[ \text{CH}_2: \text{CH} \cdot \text{CMe(OAc)} + [\text{CH}_2]_3: \text{CMe} \cdot \text{S} \rightarrow \text{S} \cdot \text{S} \cdot \text{S} + \text{S} \cdot \text{S} \cdot \text{S}; \]

the same compound is formed whether the quantity of sulphur employed is very small or greatly in excess of that required to form the monothiozonide; the acetyl group appears to protect the second ethylene linking from the action of thiozone. The thiozonide forms a dark brown, viscid syrup, \( D^2_{23} 1\cdot133 \), and has a characteristic odour. It absorbs oxygen very rapidly, and reacts both as a thio-acid and thio-base; although insoluble in alcohol, it readily dissolves in an alcoholic solution of sodium sulphide, forming a dark brown solution which contains the sodium salt, \( \text{C}_1\text{O}_{20} \cdot \text{O}_5 \cdot \text{Na}_2 \); this could not, however, be isolated. The thiozonide yields characteristic precipitates with the chlorides of antimony, arsenic, bismuth, and mercury. An ethereal solution of the thiozonide and auric chloride liberates hydrogen chloride on evaporation, leaving a brown, tarry residue of a *gold* compound, which, when heated on porcelain, leaves behind a brilliant, coherent coating of gold. The gold compound is also formed by the interaction of the thiozonide dissolved in ethyl acetate with gold sulphide.

**Linalool dithiozonide** is prepared by heating linalool with sulphur at 160°; hydrogen sulphide is evolved during the reaction, and the brown, viscid mass obtained has the approximate composition \( \text{C}_1\text{O}_{16} \cdot \text{H}_{16} \cdot \text{OS}_5 \).

With the object of ascertaining whether linalool and linalyl acetate behave in a similar manner towards ozone, equimolecular solutions of the two substances in carbon tetrachloride were added to equal volumes of a solution of ozone in carbonyl chloride at -70° until the blue colour of the ozone had disappeared. It was found that the same quantity of ozone required twice as much linalyl acetate as linalool, so that the former evidently forms a mono-, whilst the latter forms a di-ozonide.

**Sulphur Dyes as Derivatives of Thiozone.**—This part of the paper is of a somewhat technical nature. Evidence is advanced which shows that the various sulphur dyes first formed by heating many organic compounds with sulphur and sodium sulphide are thiozonides; for example, like thiozonides, they are insoluble in most solvents, soluble in alkali sulphides, and are readily oxidised by the oxygen of the air at the ordinary temperature. The fact that most sulphur dyes are oxidised by atmospheric oxygen with the liberation of sulphuric acid, and yield hydrogen sulphide when reduced, is readily explained on the
assumption that they are thiozonides containing the chromophoric group \( \text{C}S \rightarrow \text{S} \). Ris’s conclusion (Abstr., 1900, i, 419), that the sulphur liberated as hydrogen sulphide is attached to nitrogen, is very improbable.

Theory of Inorganic Polysulphides.—Although sulphur does not readily act on organic substances below 160°, yet, in the presence of sodium sulphide, action takes place at a much lower temperature. It is therefore probable that the polysulphides are closely related to thiozone. The results of work not yet published show that the alkali metals behave towards sulphur like rubidium towards oxygen (compare Erdmann and Köthner, Abstr., 1897, ii, 96); in fact, the yellow disulphide, \( \text{NaS}_2 \), corresponds with the brown oxide, \( \text{Rb}_2\text{S}_2 \). This disulphide may be represented as a thiozonate, \( \frac{\text{NaS}}{} \rightarrow \text{S} \), that is, as an additive product of the monosulphide with thiozone. Such thiozonates are among the best characterised polysulphides of the alkali metals; thus, Böttger has shown (Abstr., 1884, 1260) that alkali thiozonates containing varying, yet definite, amounts of water crystallise from solutions of polysulphides containing more or less sulphur; further, the various polysulphides, \( \text{Na}_4\text{S}_9, \text{Na}_2\text{S}_5, \text{Na}_3\text{S}_8 \) (compare Bloxam, Trans., 1900, 77, 753), when heated at 800°, yield the thiozonate, \( \text{Na}_2\text{S}_4 \). The fact that pure sulphur dyes are formed by acting on amino-phenols with an alcoholic solution of sodium thiozone, may be explained by assuming that the thiozonate partly dissociates when its alcoholic solution is warmed, yielding thiozone, \( \text{Na}_2\text{S}_4 \rightarrow \text{Na}_2\text{S} + \text{S}_3 \), which, in the nascent state, readily unites with the amino-phenol.

Constitution of Ultramarine.—Hoffmann’s conclusion (Abstr., 1879, 108), that the sulphur in ultramarine-blue is present in a similar state of combination as in the polysulphide, \( \text{Na}_2\text{S}_4 \) (sodium thiozone), cannot be correct, since it does not yield silver sulphide with silver nitrate, but is converted into silver ultramarine, in which sodium is replaced by its equivalent of silver (compare Heumann, Abstr., 1880, 217, 367; 1881, 351). Instead, the ultramarines are to be regarded as thiozonides. Hoffmann has shown that white ultramarine, \( \text{Na}_{12}\text{Al}_6\text{S}_3\text{Si}_6\text{O}_{24} \), is converted on oxidation into green, and then into blue, ultramarine, both of which also contain the three atoms of sulphur in the molecule. In strict analogy with the ultramarines, sulphur dyes are reduced by powerful reducing agents to leuco-compounds, corresponding with the white ultramarine, which are readily oxidised back to the original dye.

Chemistry of Molten Sulphur.—As has been shown, molten sulphur at 160° contains thiozone; now this substance, like sulphur dioxide, has the character of an acid anhydride, and is consequently able to bring about polymerisation of eight-membered rings (compare Harries, this vol., i, 254). Now ordinary sulphur contains eight atoms in the molecule; consequently, sulphur at 160° probably consists of thiozone, which imparts to the mass its dark colour, together with amorphous sulphur, \( (\text{S}_8)_x \), which renders the mass viscid.

Constitution of Polymeric Forms of Oxygen.—Since sulphur exists
as \( S_8 \), it is not improbable that oxygen might also exist in the polymerised form, \( C_8 \). Ladenburg and Lehmann (Abstr., 1906, ii, 509) appear to have obtained evidence of the existence of a highly polymerised form of oxygen, but Warburg and Leithäuser (Abstr., 1907, ii, 342) have thrown doubt on their results. However, it is not improbable that the octa-sulphates described by Weber (Abstr., 1885, 121) contain the eight-membered ring: 

\[
\begin{align*}
0 & \cdot 0 & \cdot 0 \cdot O \\
O & \cdot 0 & \cdot 0 & \cdot O.
\end{align*}
\]

**Theory of Vulcanised Caoutchouc.**—In the vulcanisation of caoutchouc, it is probable that the sulphur liberates thiozone, which forms a thiozonide, and that the viscid, amorphous form of sulphur, \( (S_8)_{2z} \), produced simultaneously, forms a semi-solid solution with the caoutchouc, which has a similar constitution to the viscid, amorphous form of sulphur, being a polymerised form of a dimethyleyclooctadiene (compare Harries, loc. cit.). Vulcanised caoutchouc is thus a semi-solid solution of polymerised sulphur, \( (S_8)_{2z} \), in polymerised dimethyleyclooctadiene, \((C_8H_{10}Me_2)_{2z}\), and its thiozonide. Ebonite is probably a polythiozonide of caoutchouc.

W. H. G.

**Selenium and Iodine.** Giovanni Pellini and S. Pedrina (Atti R. Accad. Lincei, 1908, [v], 17, ii, 78—81).—From a study of the melting-point curve for mixtures of selenium and iodine, the authors conclude that these elements form no compound and no mixed crystals, except within very narrow limits. The eutectic mixture melts at 58°, and corresponds almost exactly with the supposed compound, \( Se_4I_2 \).

The identical products obtained in various ways by Schneider (Pogg. Annalen, 1866, 129, 627) must be regarded as mixtures of definite composition.

T. H. P.

**Electrolytic Formation of Selenic Acid from Lead Selenate.** Frank Curry Mathers (J. Amer. Chem. Soc., 1908, 30, 1374—1378).—A study has been made of the best conditions for converting lead selenate into lead and selenic acid by electrolysis. The lead selenate is placed in a platinum dish, which serves as the cathode, and a coil of platinum wire is used as the anode. Some reduction products of selenic acid are formed during the process, but these are insoluble and can be removed by filtration. The best efficiency yield, 87%, was obtained at the ordinary temperature, with a low current density at the cathode and a thin layer of lead selenate. The best current yield, 13%, was obtained at 85°, with a low current density and a large amount of lead selenate on the cathode. Selenic acid is only produced in small quantities from lead selenate in contact with the anode.

E. G.

**Structural Isomerism. Preparation of Asymmetric Selenites.** Luigi Marino (Atti R. Accad. Lincei, 1908, [v], 17, i, 858—866; Zeitsh. anorg. Chem., 1908, 59, 450—460).—If the author’s views concerning sulphurous acid (this vol., ii, 106) hold also for selenious acid, it should be possible to obtain asymmetric selenites. To investigate this question, the action of selenious acid on lead peroxide has been studied. In this way, besides ordinary lead selenite,
a salt, Pb₂Se₂O₇, has been obtained as a sulphur-yellow, crystalline powder. When treated with potassium carbonate solution, this salt yields 1 mol. of lead peroxide and 1 mol. of lead oxide per mol., whilst the addition of dilute nitric acid to a solution of the salt in 15% sodium hydroxide solution precipitates the sesquioxide, thus: Pb₂Se₂O₇ = Pb₂O₃ + 2SeO₂. When heated at 200°, the yellow salt gradually changes into a white isomeride, exhibiting different reactions from the yellow form; for example, it does not yield lead peroxide when boiled with alkali carbonate solutions. When heated at 40—50° with dilute sulphuric acid and potassium permanganate, the white isomeride absorbs 1 atom of oxygen per mol.; under the same conditions, the yellow form is stable, but after long heating to 80° it absorbs 2 atoms of oxygen per molecule.

On the basis of these results, the author proposes the constitutions:

\[ \text{O} \overrightarrow{\text{Pb}} \cdot \text{O} \cdot \text{SeO}_2 \quad \text{and} \quad \text{O} \overrightarrow{\text{Pb}} \cdot \text{O} \cdot \text{SeO}_2 \]

Yellow form.

The author regards these results as lending further support to the structural formula \( \text{Pb} \overrightarrow{\text{O}} \) for lead peroxide.

Solutions of Metals in Non-metallic Solvents. III. Apparent Molecular Weight of Sodium Dissolved in Liquid Ammonia. Charles A. Kraus (J. Amer. Chem. Soc., 1908, 30, 1197—1219. Compare Abstr., 1907, ii, 935; this vol., ii, 486).—A study of the molecular weight of sodium and potassium in liquid ammonia was made by Joannis (Abstr., 1893, ii, 115; 1906, ii, 161) by determining the change in the vapour pressure of the solvent on addition of a known quantity of the metal. Franklin and Kraus (Abstr., 1899, ii, 202) determined the molecular weight of sodium and lithium in ammonia by the boiling-point method, and obtained results for sodium which were lower than those of Joannis. The results of Franklin and Kraus are regarded as the more trustworthy, as the solutions employed were less concentrated. The present investigation was undertaken with the object of determining the molecular weight of sodium in still more dilute solutions.

A method has been devised for measuring the changes of the vapour pressure of liquid ammonia on the addition of sodium, which gives results of an accuracy within about 1% when the total pressure change is as small as 10 mm. The apparatus employed is described with the aid of a diagram. The determinations were made at about 15°, and the concentration varied from one to ten litres per gram-atom of sodium.

The results show that in dilute solutions the molecular weight of sodium is as low as 23, and in solutions of lower concentration than 0·1N is probably even lower. In the more concentrated solutions, the pressure change is smaller than would be expected from Raoult's law. The form of the complete vapour-pressure curve indicates that this deviation is due to a tendency of the solutions to separate into two phases, for which the critical point lies near 3 mols. % of sodium.
It has been shown previously (Abstr., 1907, ii, 936) that separation takes place in this region at lower temperatures. Raoult's law cannot therefore be applied to solutions of greater concentration than 0.1N.

E. G.

Solutions of Metals in Non-metallic Solvents. IV. Material Effects accompanying the Passage of an Electric Current through Solutions of Metals in Liquid Ammonia. Migration Experiments. CHARLES A. KRAUS (J. Amer. Chem. Soc., 1908, 30, 1323—1344. Compare Abstr., 1907, ii, 935; this vol., ii, 486, and preceding abstract).—In the first paper of this series, it was suggested that the electrical conductivity of metals is due to ionisation. In this connexion, a study has now been made of the question as to whether the transport of matter accompanies the current through solutions of metals in liquid ammonia, and quantitative migration experiments have been carried out with solutions of sodium. Such solutions are well adapted for the purpose, since they possess a characteristic blue colour, which renders concentration changes visible in solutions as dilute as N/40,000. It has been found that the liquid at the surface of the anode becomes colourless, whilst at the cathode the colour becomes more intense. Experiments have also been made with solutions of potassium in potassamide dissolved in liquid ammonia. In this case, it has been found that the blue colour travels towards the anode, whence it might be concluded that the metal in the solution travels in this direction. It has already been shown, however, that the metal travels in the direction of the positive current, and the direction of movement of the colour is not therefore due to a movement of the metal in this direction, but is due to interaction between the negative metal anions and potassamide, whereby free metal is reversibly produced.

From the results of these experiments, it is concluded that the process of conduction in solutions of metals is ionic. The metal constitutes the positive ion, and is identical with the positive ion of a salt of the metal dissolved in ammonia. The negative ion consists of an electron surrounded by molecules of the solvent, and is in equilibrium with ammonia according to the equation: $\epsilon^- (\text{NH}_3)_n = \epsilon^+ + n\text{NH}_3$. This electron is also in equilibrium with the metal cation and the neutral metal atoms, thus: $\text{M}^+ + \epsilon^- = \text{M}_n\epsilon$, where $\text{M}^+$ is the cation and $\text{M}_n\epsilon$ the neutral atom.

E. G.

Oxidation of the Ammonia in Ammonium Persulphate. MARIO G. LEVI and E. MIGLIORINI (Gazzetta, 1908, 38, ii, 10—20. Compare Abstr., 1907, ii, 81).—Experiments made by heating solutions of ammonium persulphate at 100°, 75°, and 50° show that the ammonia of ammonium persulphate may undergo marked oxidation even in solutions which are originally neutral or almost so, and become more and more acid owing to the sulphuric acid liberated; this oxidation is rendered evident by the evolution of nitric oxide. The addition of sodium hydroxide in increasing proportions to the persulphate solution causes
the oxidation first to diminish to a minimum and then to increase indefinitely.

When no alkali is present, there seems to be a true oxidation of the ammonium ions, resulting in the formation of nitric acid in the solution. Corresponding with this oxidation, the amount of oxygen evolved is less than the theoretical quantity. When the decomposition takes place in presence of alkali, the reactions become more complicated; there may then be oxidation in the liquid phase and also in the gaseous phase, especially at the surface of the separation of liquid and gas, where the ammonia may be oxidised directly by part of the oxygen evolved. The courses of these two reactions would depend on the concentrations of the ammonia in the two phases; in general, oxidation takes place more readily and more rapidly in the liquid phase.

The oxidation is diminished in absolute amount by lowering the temperature, and is augmented by increasing the concentration of the persulphate.

T. H. P.

Combination of Nitrogen with Calcium Carbide. Gino Pollacci (Zeitsch. Elektrochem., 1908, 14, 565—566).—Potassium carbonate accelerates the combination of nitrogen and calcium carbide; the rate of combination is greatest when the mixture contains 4% of potassium carbonate. Increase of pressure also accelerates the reaction, but the acceleration practically reaches a limit at 2 atmospheres, further increase of pressure having little effect. Under the most favourable conditions, the conversion is complete in one hour at 900°.

T. E.

Preparation of Nitrides from Metallic Oxides or Salts with the Aid of Atmospheric Nitrogen. Wilhelm Borchers and Erich Beck (D.R.-P. 196323).—A metal capable of combining with nitrogen is used in the form of a fusible salt, or of its oxide mixed with a fusible fluoride. The anode compartment resembles a gas-holder dipping into a layer of some fusible metal capable of forming a fusible alloy with the metal of the salt or oxide. The fused metallic salt or mixture of oxide and fluoride is placed within the inverted anode compartment and above the layer of fused metal. The anodes are composed of some refractory material, whilst the layer of fused metal forms the cathode. On electrolysis, the metal capable of combining with nitrogen is set free at the fusible cathode and alloys with it, and thus passes from under the anode compartment.

Arrived at the outer parts of the cathode vessel, the alloy meets a current of nitrogen, with which the liberated metal combines, forming a nitride which can be removed when necessary.

In preparing magnesium nitride, the cathode vessel contains fused zinc, and the anode liquid consists of a mixture of magnesia and an alkali fluoride.

On passing the current, the liberated magnesium alloys with the zinc, and subsequently combines with the nitrogen blown into the fused metal.

G. T. M.
Preparation of Alloys of Metals which Form Nitrides.  
Erich Beck (Metallurgie, 1908, 5, 504—521).—The conditions have been studied for the electrolytic preparation of alloys, especially of magnesium, capable of yielding ammonia on treatment with nitrogen and subsequent decomposition of the nitride by steam. Tin or lead may be used as the cathode metal. When the eutectic mixture of sodium and potassium fluorides (m. p. 702°) is used as the flux, magnesium oxide is readily dissolved, an addition of 10% lowering the m. p. to 677°, but, on electrolysis, only alkali metals are set free. A mixture of calcium and magnesium fluorides also dissolves magnesium oxide, and gives good results when the cathode metal is agitated. The eutectic point of calcium and magnesium fluoride lies at 945° and 48% CaF₂; mixed crystals are not formed. Barium and strontium fluorides, on the other hand, form only mixed crystals. Mixtures of barium fluoride with the calcium-magnesium fluoride eutectic give a curve having a marked eutectic point at 790°. By the addition of magnesium oxide to this mixture, the melting point is first depressed slightly, further additions raising it considerably. This mixture gives the best results, the magnesium oxide being added gradually, but owing to its high density, a part of the magnesium rises to the surface and is burnt.

If chlorides are used instead of the fluoride-oxide mixture, carnallite gives the best results.

C. H. D.

Acid Phosphates. Nicola Parravano and Aldo Meili (Atti R. Accad. Lincei, 1908, [v], 17, ii, 33—41).—The authors have prepared the three acid phosphates: NaH₂PO₄, H₃PO₄; KH₂PO₄, H₃PO₄ (compare Staudenmaier, Abstr., 1894, ii, 137), and (NH₄)H₂PO₄, H₃PO₄, of which they have determined the solubility in phosphoric acid and the behaviour towards water. The phosphoric acid used, m. p. 40°6°, was specially purified and freed from pyrophosphoric acid.

The sodium salt, NaH₂PO₄, H₃PO₄, forms rosettes of long needles or small prisms, m. p. 126—127°. The freezing-point curve of its aqueous solution has three branches, corresponding with the separation of ice, NaH₂PO₄, and NaH₂PO₄, H₃PO₄, respectively.

The potassium salt, KH₂PO₄, H₃PO₄, for which Staudenmaier (loc. cit.) gave m. p. 127°, melts only partly at 127°5°, forming a liquid solution of KH₂PO₄ in H₃PO₄, whilst part of the KH₂PO₄ remains in the solid state: x[KH₂PO₄, H₃PO₄] → [xH₃PO₄ + yKH₂PO₄] + [x−y]KH₂PO₄; at 139°, the whole of the KH₂PO₄ dissolves. The freezing-point curve of its aqueous solutions has two branches, corresponding with the separation of ice and KH₂PO₄, respectively.

The ammonium salt, (NH₄)H₂PO₄, H₃PO₄, forms shining, deliquescent needles, and, on heating, behaves like the potassium salt; at 77—78°, it undergoes partial fusion, forming a solution of (NH₄)H₂PO₄ in H₃PO₄, together with solid (NH₄)H₂PO₄, whilst at 118° perfect solution occurs. Its curve of solubility in phosphoric acid has two branches meeting at 78°, which is the transformation point of the salt; one branch corresponds with the separation of (NH₄)H₂PO₄, H₃PO₄, and
the other with that of (NH₄)H₂PO₄. In contact with water it decomposes rapidly. T. H. P.

**Polyphosphates.** Nicola Parravano and G. Calcagni (Atti R. Accad. Lincei, 1908, [v], 17, i, 731—738).—The various supposed polyphosphates can be considered theoretically as formed by the union of pyrophosphate and metaphosphate in various proportions; thus the salt Na₅P₃O₁₀ is Na₄P₂O₇ + NaPO₄, the salt Na₃P₄O₁₃ is Na₄P₂O₇ + 2NaPO₄, and so on. The authors have accordingly studied the freezing-point curve of mixtures of sodium pyrophosphate and metaphosphate in various proportions as well as the curve obtained with the corresponding potassium salts. Both curves consist of two continuous branches meeting at a eutectic point; the shape of the curves indicates the non-existence of any compounds of metaphosphate and pyrophosphate, so that the various polyphosphates which have been described are probably mere mixtures of the two salts.

W. A. D.

**Action of Phosphoric Acid on Silicic Acid and Silicate Glass.** Karl Hütten (Zeitsch. anorg. Chem., 1908, 59, 216—224. Compare Mylius and Meusser, Abstr., 1905, ii, 316).—When finely-powdered silica is heated in a quartz vessel with excess of metaphosphoric acid, a clear solution is at first obtained, from which, on continued heating, silicyl phosphate, SiO₂P₂O₇, separates in minute crystals (Hautefeuille and Margottet, Abstr., 1883, 782). The same compound is obtained by heating silicon chloride with phosphoric acid.

Silicyl phosphate is not decomposed by boiling water, but on heating strongly, it loses part of the phosphoric oxide and forms amorphous products, which are decomposed by water. The compound itself has also been obtained in an amorphous hydrated form from its solution in metaphosphoric acid, and this modification is being further investigated.

The action of phosphoric acid on the silicates found in glass has been investigated; in most cases, silicyl phosphate and metaphosphates are produced. Orthophosphoric acid scarcely acts on glass at the ordinary temperature, but does so at 100—150°. Phosphoric oxide can be sublimed in glass vessels without affecting them. G. S.

**Silicic Acids obtained by Tschermak.** Jakob M. van Bemmelen (Zeitsch. anorg. Chem., 1908, 59, 225—247; Chem. Weekblad, 1908, 5, 567—589).—A criticism of the formula assigned to the silicic acids obtained by Tschermak (Abstr., 1905, ii, 816) by digesting natural silicates with hydrochloric acid. These formulæ are based on the changes which are observed in the rate of loss of water by the hydrogels when the proportion of water to silica has attained certain values. According to the author, these changes cannot be supposed to differentiate between the chemically-combined and the mechanically-held water, and furnish no basis for the deduction of formulæ for the various preparations of silicic acid. The hydrogels obtained from the silicates are colloidal absorption
Dissociation of Molten Silicates. II. Cornelio Doelter (Monatsh., 1908, 29, 607—644. Compare this vol., ii, 178).—The paper deals with the conductivity and the polarisation of augite, albite, labradorite, and diopside in the molten and in the solid states at high temperatures. In measuring the conductivity of molten salts, a sharper minimum in the telephone is obtained by using electrodes set far apart and placed in a liquid of small cross section. Since the use of capillary vessels is excluded on account of the viscosity of molten silicates, the author employs a conductivity trough of quartz and kaolin of parallelepiped shape, 24—25 mm. long and 1 sq. cm. in area, in which the electrodes are fixed as in his former experiments, not quite at the ends of the vessel. The trough is filled with the powdered silicate, and the conductivity measured at temperatures up to those at which the silicate sinters and fuses. Both direct and alternating currents have been employed, but measurements by the former are only of secondary importance, and do not agree with the values obtained with an alternating current, except in the case of augite.

Experiments, mainly of a qualitative nature to ascertain whether polarisation occurs in the solid as well as in the liquid state, indicate that such a phenomenon is not manifest in crystalline silicates unless the vitreous modification is also present; only in the neighbourhood of the m. p. does slight polarisation occur. For example, with augite, m. p. about 1200°, polarisation is not evident below 1180°, but becomes quite distinct at 1250°; albite, which is especially liable to resolidify in the vitreous state, shows polarisation at 900°, and with strong currents at 1100°, electrolysis occurs, aluminium being deposited on the platinum cathode.

From van’t Hoff’s equation: \( \frac{d \log \varphi}{dT} = -\frac{q}{R}T \) is derived the expression: \( \log W = \frac{v}{T} + C \), according to which the graphic representation of the relation between the logarithm of the specific resistance, \( W = \frac{1}{x} \), and the reciprocal of the absolute temp., \( T \) (\( v \) and \( C \) being constants), is a straight line. The author’s experiments show that the formula only holds for temperatures removed from the m. p.

The conductivity of a crystalline silicate first becomes measurable at about 500°, increases with the temperature, and shows a marked augmentation in the neighbourhood of the m. p., causing the conductivity-temperature curve to show a break; a gradual rounding of the curve is exhibited when the molten silicate passes into the vitreous form. In general, the temperature-conductivity curve consists of two parts, one, corresponding with temperatures from 200° below the m. p. up to the m. p., is nearly vertical, and the other, representing the conductivity of the liquid phase, is nearly horizontal. The fact that a crystalline silicate shows a sudden change in conductivity when passing into the liquid or into the amorphous state, is the most important result of the investigation. The paper concludes with theoretical discussions.
of the preceding fact and of the relation between crystalline structure and dissociation.

C. S.

Search for Possible New Members of the Inactive Series of Gases. Sir William Ramsay (Proc. Roy. Soc., 1908, 81, A, 178—180. Compare following abstract).—As the periodic system would appear to indicate the existence of two or three elements of the helium group heavier than xenon, the heavier portions of the gas, after the fractional distillation of 120 tons of liquid air, were investigated by Moore (loc. cit.); no positive result was obtained, and it is probable that higher members either do not exist in the atmosphere or that they disintegrate during the process of separation.

It is suggested that the emanations from radium, thorium, and actinium may be the missing inactive elements. Some support is lent to this view by the fact that the atomic weight of radium emanation (deduced from diffusion experiments) appears to be about 172, so that it would fit into the vacant space below neon. The most recent experiments, however, indicate that the atomic weight of the emanation may be over 200, which would bring it into the same horizontal period as radium, thorium, and uranium. Nothing very definite is known as to the respective atomic weights of the thorium and actinium emanations.

G. S.

Heavy Constituents of the Atmosphere. Richard B. Moore (Proc. Roy. Soc., 1908, 81, A, 195—209).—The heavy gases from about 120 tons of liquid air have been examined for the presence of gases heavier than xenon, with negative results.

In the first experiment, the heavy residues from 19 tons of liquid air were condensed in liquid oxygen. After most of the oxygen had evaporated, the remainder was removed by means of melted phosphorus, and the nitrogen and other impurities were also removed by means of the appropriate reagents. The residue (about 6 litres of inactive gas) was then fractionated, but the final fraction was not heavier than xenon, and the spectrum afforded no evidence of the presence of a new gas. The water with which the gas had been in contact was boiled, and the gas given off added to the main bulk before fractionation.

In a second experiment, the residues from 100 tons of liquid air were worked up by a modified method, in which the gases did not come into contact with much water, but the results were negative in this case also. The methods of fractionation employed are fully described.

The magnesium and lime used to extract the nitrogen were examined to detect possible reaction products, with negative results.

G. S.

New Reaction for the Production of Sodium Carbonate. D. Crispo (Bull. Soc. chim. Belg., 1908, 22, 292—295).—The author finds that, contrary to previous statements, sodium carbonate can be rapidly and easily prepared by the interaction, under suitable conditions, of calcium carbonate and sodium silicate. A syrup of
sodium metasilicate is heated with chalk, the mass is then dried at a moderate temperature, and lixiviated with water to remove the sodium carbonate. The polysilicate, $3\text{SiO}_2\cdot\text{Na}_2\text{O}$, does not react with calcium carbonate.

Details are given of an industrial process for preparing the metasilicate from sodium sulphate by heating this salt with charcoal and sand.

W. O. W.

The Reciprocal Salt Pair $\text{NaCl}-\text{K}_2\text{SO}_4$; $\text{KCl}-\text{Na}_2\text{SO}_4$. Ernst Janecke (Zeitsch. physikal. Chem., 1908, 64, 343—356. Compare this vol., ii, 808).—The freezing-point and transformation curves of the four binary systems concerned confirm earlier results ($\text{KCl}-\text{K}_2\text{SO}_4$ and $\text{NaCl}-\text{Na}_2\text{SO}_4$), Ruff and Plato, Abstr., 1903, ii, 588; $\text{NaCl}-\text{KCl}$, Kurnakoff and Schemtschuschny, Abstr., 1906, ii, 443; $\text{K}_2\text{SO}_4-\text{Na}_2\text{SO}_4$, Nacken, Abstr., 1907, ii, 611). The formation of a compound of sodium and potassium sulphates in the solid state, assumed by Nacken, is not confirmed.

The results are recorded in a space model, the base of which is a square representing the proportions of the four salts present, and the ordinates are the temperatures of solidification. Two classes of mixed crystals are formed, and a minimum freezing point is found at the composition $(\text{Na}_2)_{43}(\text{K}_2)_{57}(\text{Cl}_2)_{46}(\text{SO}_4)_{54}$.

C. H. D.

The Silver Hydrogel in Photographic Films. Lüppo-Cramer (Zeitsch. Chem. Ind. Kolloide, 1908, 3, 33—36).—Silver nitrate is reduced by pyrogallol and sodium carbonate to a black, finely-divided silver, which is quickly bleached by mercuric chloride, whereas pyrogallol alone gives a light-coloured, coarse-grained precipitate, to which mercuric chloride gives a dark colour. The author has tried many other reducing agents. In general, reduction in presence of a solvent of the silver salts, such as sodium sulphite, thiosulphate, or thiocyanate, or ammonia, tends to give the light-coloured silver, whilst any circumstance which tends to prevent the coalescence of the reduced silver, for example, reduction of an insoluble silver salt or enclosure of the salt in a gelatin film, yields the dark-coloured modification. The silver hydrogel of the photographic film is the dark-coloured form. Collodion does not hinder the coalescence of the silver particles to nearly the same extent as gelatin.

T. E.

Decomposition of Certain Salts of Silver. Angelo Angeli and Guerriero Marchetti (Atti R. Accad. Lincei, 1908, [v], 17, i, 695—697).—Whereas the sodium salt of nitrohydroxylamic acid decomposes into sodium nitrite and hyponitrite, thus: $2\text{NaON} \cdot \text{NO}_2\text{Na} = \text{NaO} \cdot \text{N} \cdot \text{ONa} + 2\text{NaNO}_2$, the silver salt gives silver nitrite, nitric oxide, and silver according to the equation: $\text{AgON} \cdot \text{NO}_3\text{Ag} = \text{NO}_3\text{Ag} + \text{NO} + \text{Ag}$. It is possible that the group NOAg is first eliminated and then decomposed; this view is strengthened by the fact that benzene-sulphhydrazinic acid, which is decomposed by alkalis into benzene-sulphinic acid and a hyponitrite, gives an unstable silver salt, which readily forms silver sulphinate, nitric oxide, and silver:

$$\text{OAg} \cdot \text{SO} (\text{C}_6\text{H}_5) \cdot \text{NOAg} = \text{C}_6\text{H}_5 \cdot \text{SO}_2\text{Ag} + \text{NO} + \text{Ag}.$$
Pernitrosocamphor gives a yellow silver derivative, which soon blackens, owing to the formation of silver and a substance, \( \text{C}_{10}\text{H}_{15}\text{O}_{2}\text{N}_{2}\text{Ag} \), which melts at 168°; the change occurring is:

\[
2\text{C}_{10}\text{H}_{15}\text{O}_{2}\text{N}_{2}\text{Ag} = 2\text{C}_{10}\text{H}_{15}\text{O}_{2}\text{N}_{2} + \text{Ag}_2.
\]

W. A. D.

Crystallisation of the Alkaline-earth Oxides, especially of Calcium Oxide, from their Nitrates. Gottfried Brügelmann (Zeitsch. anorg. Chem., 1908, 59, 248—270).—When the carefully-purified nitrates of calcium, strontium, and barium are heated to the temperature of decomposition, the corresponding oxides separate out in the form of regular cubes. Calcium and strontium oxides yield well-developed macroscopic crystals. The formation of the calcium oxide crystals is greatly facilitated by the addition of 0.25% to 0.6% of calcium hydroxide to the molten nitrate.

The author's very numerous experiments lead to the conclusion that the usual precautions adopted for the production of well-developed crystals (the use of large quantities of material, slow cooling, and freedom from mechanical disturbance) are not the only important factors of importance. A study of the crystallo-genetic peculiarities is essential.

H. M. D.

Relation of Changes of Solubility of Calcium Sulphate and its Rate of Hydration. Paul Rohland (Zeitsch. Elektrochem., 1908, 14, 421—422).—The effect of twenty-two substances on the rate of hydration of gypsum is tried. Those which increase the solubility of the gypsum in water, also increase its rate of hydration, and vice versa. The same substance may have opposite effects, for example, gypsum is less soluble in dilute solutions of sodium, ammonium, and magnesium sulphates than it is in water, whereas it is more soluble in strong solutions. Hydration is retarded by dilute solutions, and accelerated by strong ones.

T. E.

Preparation of Colloidal Amorphous Forms of Crystalline and Soluble Salts of the Alkaline-earth Metals. P. P. von Weimann (Zeitsch. Chem. Ind. Kolloide, 1908, 3, 89—91).—Gelatinous precipitates are obtained in general by rapid separation of a substance from a solution in which it is very sparingly soluble. High viscosity of the solvent is also favourable. The thiocyanate of an alkali or alkaline-earth metal is dissolved in a mixture of amyl alcohol and ether, and mixed with a similar solution of an acid. In this way the following salts have been obtained in the gelatinous form: potassium, sodium, ammonium, calcium, strontium, and barium chlorides, bromides, and nitrates, and the sulphates of potassium, sodium, and ammonium. The sulphates and phosphates of the alkaline-earth metals are obtained in the gelatinous form from solutions in any of the lower aliphatic alcohols.

T. E.

Isomorphism of Calcium and Manganese Bisilicates. A. S. Ginsberg (Zeitsch. anorg. Chem., 1908, 59, 346—363).—A freezing-point curve for the system wollastonite-rhodonite has been obtained by observations on mixtures containing different proportions
of the two silicates. Calcium silicate melts at 1512°; manganese silicate at 1218°. The temperatures corresponding with the commencement of crystallisation and with complete solidification are given for a series of mixtures. The minimum temperature of 1180° corresponds with a mixture containing 12⋅8 molecular % of calcium silicate.

From the nature of the freezing-point diagram, the conclusion is drawn that the two silicates form a complete series of mixed crystals, and that wollastonite and rodonite are isomorphous. Since rhodonite is triclinic, the existence of a polymorphic, monoclinic modification must be assumed in order to explain the formation of the monoclinic series of mixed crystals, with which the mineral bustamite is to be identified.

Measurements of the density and hardness of mixtures containing various proportions of the two silicates have been made, which show that these properties vary continuously with the composition. The curve representing the hardness as a function of the composition exhibits a maximum for a mixture containing 15% manganese silicate. The density of wollastonite is 2⋅919, and that of rhodonite 3⋅350.

H. M. D.

Action of Soluble on Insoluble Substances. William Oechsner De Coninck and L. Arzalier (Bull. Acad. roy. Belg., 1908, 577—578. Compare Abstr., 1907, ii, 952).—When barium sulphate (1 mol.) is heated at 100° for 620 hours with methylamine hydrochloride (2 mols.) in aqueous solution, a partial double decomposition ensues. A similar result was also obtained in the case of barium sulphate (1 mol.) and an aqueous solution of potassium chloride (2 mols.) at the end of five months, heated at 90—95° during two-fifths of the period.

E. H.

Microscopic Study of Mortar. Gino Gallo (Gazzetta, 1908, 38, ii, 142—156. Compare Stern, this vol., ii, 589).—Microscopic study of the changes occurring in a mortar shows that the absorption of carbon dioxide by the calcium hydroxide present is intimately related to the presence of water, and, since the calcium carbonate formed is distinctly crystalline, it is concluded that both the lime and the carbon dioxide must be in solution before the reaction takes place. A mortar prepared with a deficit of water lacks solidity and has low resisting properties, owing to the fact that the calcium carbonate formed under these conditions forms a coarse net-work; similar defects are observable in mortar made with coarse sand, the calcium carbonate deposited in the large interstices not adhering to all the neighbouring sand granules.

The injurious effect exercised by the presence of magnesia in a mortar is explained by the slight solubility of the magnesia in the
ABSTRACTS OF CHEMICAL PAPERS.

water present and by the slow absorption of carbon dioxide by the solution formed.

When the water is completely eliminated from a mortar, chemical action ceases, and in the interior of old mortars in which the carbon dioxide could not reach the lime before the water evaporated completely, free lime is found. T. H. P.

Microscopic Study of Mortar and Pozzolana. Gino Gallo (Gazzetta, 1908, 38, ii, 156—204).—The author reviews briefly previous work on pozzolana and its value as a hydraulic mortar. His own experiments on the setting of mortars prepared from pozzolana were made with the microscope (see preceding abstract).

All the mortars examined exhibited a distinctly crystalline border of calcite, which forms immediately the mortar is made, and has a thickness of about 0.1 mm.; when good pozzolana is employed, the thickness of this layer does not change appreciably. This calcitic coating prevents water from finding ready access to the interior of the mortar, and so hinders the solution and removal of the lime.

The first phenomenon observable in the setting of these mortars is the hydration, by means of the lime water, of the silica and alumina, which swell so as to fill the whole space previously occupied by air and water, and yield an impermeable mass bestowing resistance on the mortar. Then follows the formation of soluble calcium aluminate, which, in presence of excess of lime and in supersaturated solution, deposits crystals of the calcium aluminate, \( \text{Al}_2\text{O}_3.3\text{CaO}.10\text{H}_2\text{O} \), which is stable only in presence of calcium hydroxide solution, and is decomposed by water; this crystallisation binds together the various particles which exist as inclusions in the crystals. The limiting surfaces between the flocculent portions and the spaces left by these then become the seat of capillary forces, by means of which the silica attracts the lime into its pores and thus forms nodules in which the lime gradually gives up its water of hydration and crystallises as calcium monohydrate, thus determining complete adhesion of the various parts. The more rapidly the swelling attains its maximum and the greater the latter, the more satisfactory will be the setting of the mortar.

The increases in volume of various specimens of pozzolana in presence of calcium hydroxide solution have been measured. It is found that this increase is related directly to the amount of lime absorbed, and that it is considerably increased by renewing the calcium hydroxide solution from time to time. The action of calcium hydroxide also causes an increase in the amounts of alumina and silica which can be dissolved by dilute acid.

The value of a pozzolana for the preparation of hydraulic mortar may be determined by the following measurements: (1) Increase of volume with calcium hydroxide solution. (2) Electrical conductivity (compare Giorgis and Gallo, Abstr., 1906, ii, 447). (3) Amounts of silica and alumina dissolved by treating with 5% sodium hydroxide solution on the water-bath for fifteen minutes. For good pozzolana, these amounts are almost constant, even where the material has
been previously treated with dilute acid; but for inferior materials, such as ashes from Vesuvius and Bassano, previous disgregation with hydrochloric acid renders increasing amounts of silica and alumina capable of solution in 5% sodium hydroxide solution. T. H. P.

Liquefaction and Sublimation of Certain Sulphides. WILHELM BILTZ (Zeitsch. anorg. Chem., 1908, 59, 273—284).—The sulphides, contained in porcelain or magnesia tubes through which a current of dry nitrogen was passed, were heated by means of an electrical resistance furnace. The sublimation or liquefaction was observed by means of a telescope, the temperature being registered by a thermo-element or a Wanner pyrometer. The following melting points are recorded: synthetic lead sulphide, 1100°, sublimation commencing at 950°; galena from Freiberg, 1112°±2°; ferrous sulphide, 1197°±2°; nickel sulphide, 797°±2°; cobalt sulphide, >1100°. Zinc, cadmium, and mercuric sulphides sublime without melting. The temperatures at which sublimation begins are as follows: zinc blende from Santander, 1178°±2°; synthetic zinc sulphide in the form of wurtzite, 1185°±6°; cadmium sulphide, 980°; cinnabar and precipitated mercuric sulphide, 446°±10°.

Stannous sulphide exhibits two melting points. Its behaviour was traced by a study of cooling and heating curves. The lower melting point is about 870°, and, as the temperature is raised from 1000° to 1100°, the viscosity of the liquid increases very quickly, so that at the latter temperature the substance exhibits the properties of a solid. At about 1200°, liquefaction again takes place. The phenomenon has not yet been explained.

Compounds of Lead with Nitrous Acid. ALBERTO CHILESOTTI (Atti R. Accad. Lincei, 1908, [v], 17, i, 824—834).—The author gives a résumé of the various lead nitrites which have been described, many of which are probably not individual compounds.

By mixing equivalent proportions of solutions of lead chloride and silver nitrite saturated at 25° and concentrating the liquid, first by freezing and then by evaporation over sulphuric acid, he has obtained the hydrate, Pb(NO₂)₂.H₂O (compare Lang, J. pr. Chem, 1862, 86, 300), and the anhydrous salt, Pb(NO₂)₂, mixed with a little lead oxide and lead nitrate. The electrical conductivity of lead nitrite solutions at 25° is as follows:

<table>
<thead>
<tr>
<th>v</th>
<th>16</th>
<th>32</th>
<th>64</th>
<th>128</th>
<th>256</th>
<th>512</th>
<th>1024</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\Lambda)</td>
<td>59.4</td>
<td>72.3</td>
<td>85.5</td>
<td>98.9</td>
<td>111.3</td>
<td>122.1</td>
<td>129.7</td>
</tr>
</tbody>
</table>

For the more concentrated solutions, the conductivity of the nitrite is somewhat less than that of the nitrate or chloride, but at greater dilutions the differences are small. The value of \(\Lambda_{1024}/\Lambda_{25}\) is 27·6 for the nitrate, 42·1 for the chloride, and 57·4 for the nitrite. It is probable, from their conductivity and from their intense yellow colour, that solutions of lead nitrite contain complex anions of the type \(\text{Ag(NO}_2\text{)}_2^+\) or \(\text{Hg(NO}_2\text{)}_4^{2+}\) (compare Abegg and Pick, Abstr., 1906, ii, 833). T. H. P.
Planimetric Analysis of Alloys and the Structure of Phosphor Copper. Alfred K. Huntington and Cecil H. Desch (Trans. Faraday Soc., 1908, 4, 51—58).—The method depends on the measurement, by means of a planimeter, of the relative areas occupied by the different constituents on a polished and etched section of an alloy. It is applicable to alloys for which two solid constituents are visible in the same section, and often also when crystals of a solid constituent are surrounded by a eutectic, but is only to be employed when the alloys are in a known state of equilibrium.

In making an observation, the highly magnified image of the section is projected on a sheet of paper, the outlines of one of the constituents traced with a pencil, and the crystals shaded. A boundary line is drawn to enclose the pattern to be measured, and the shaded area measured with the planimeter. The agreement of planimetric and ordinary analysis for the alloys of copper and aluminium is excellent. The chief recommendation of the method is its rapidity.

When the pattern is very complicated, or made up of many small and detached portions, better results are obtained by dividing the field into squares, estimating the relative shaded areas, and averaging.

Heyn and Bauer, who have investigated the phosphor-copper alloys (Abstr., 1906, ii, 855), observed that the copper areas determined planimetrically were larger than calculation from the composition would indicate. The alloys in question (up to 8% phosphorus) consist mainly of copper crystals and a eutectic copper—copper phosphide, and it is now shown that the difference is due to the fact that the crystals of copper gradually increase in size after solidification by withdrawing copper from the eutectic surrounding them, so that each crystal is surrounded by a clear belt free from copper. The areas of these belts have been determined, and when a corresponding correction is applied to the areas of the copper crystals, the results of the planimetric and direct analysis show excellent agreement.

The paper is illustrated with photomicrographs. G. S.

Constitution of the Copper-Zinc-Nickel Alloys, and of the Binary Systems Copper-Nickel, Copper-Zinc, and Nickel-Zinc. Victor E. Tafel (Metallurgie, 1908, 5, 343—352, 375—383, 413—430).—The study of the copper-nickel equilibrium diagram completely confirms the results of Guertler and Tammann (Abstr., 1907, ii, 174). The results obtained for the copper-zinc series differ somewhat from those of Shepherd (Abstr., 1904, ii, 662). The existence of the compound Cu$_2$Zn$_3$ (m. p. 830°) is established, and that of the compound Cu$_2$Zn, indicated by other methods, is quite consistent with the thermal diagram. The compounds CuZn$_6$, CuZn$_4$, CuZn$_2$, CuZn$_2$, and CuZn, described by various authors, certainly do not exist. The alloys, especially in the neighbourhood of 50% Zn, have considerable tendency to liquate.

The nickel-zinc alloys (this vol., ii, 105; compare Voss, ibid., ii, 197) have been more fully investigated. The only compound recognised is NiZn$_3$, a highly brittle substance giving a characteristic coloration with dilute nitric acid. Owing to loss of zinc by volatilisa-
tion, it was found necessary to complete the diagram above 50% Ni by extrapolation from the ternary model.

Alloys of copper, nickel, and zinc liquate considerably, the lower portions of the ingots becoming generally richer in nickel. The thermal diagram, constructed as a projection on a triangular base, represents determinations of 92 different alloys. Neither a ternary compound nor a ternary eutectic point was found. The surface of the temperature-concentration model consists of three surfaces, each representing the separation of a series of primary mixed crystals. The third of these, the richest in zinc, is separated from the second by a eutectic line. The observations have also been plotted in the form of vertical sections through the model, the complicated changes taking place in the solid alloys being also represented in this way.

The alloys of technical importance, such as German silver, consist of homogeneous mixed crystals. Alloys containing 15·3—20% Ni, 73—80% Cu, and 7% Zn have a remarkable resemblance to silver, both in their colour when polished and in ductility.

The structure of the alloys, and the transformations undergone during cooling, are illustrated by fifty photomicrographs.

C. H. D.

Cuprous Ammonia Halides. Stewart J. Lloyd (J. Physical Chem., 1908, 12, 398—403).—Evidence of the existence of various cuprous ammonia halides was obtained by saturating the cuprous halides at 0° with dry ammonia, and measuring the vapour pressure at a constant temperature as the ammonia was gradually removed. The curves, obtained by plotting vapour pressures against the ammonia content of the halides, show discontinuities in the vapour pressure corresponding with the following compounds, of which the colour and the approximate melting point are recorded: Cu₂L₂6NH₃, light green, 105°; Cu₂L₂3NH₃, dark brown, 117°; Cu₂Br₂6NH₃, green, 115°; Cu₂Br₂3NH₃, brown, 135°; Cu₂Cl₂6NH₃, green, 123°; Cu₂Cl₂3NH₃, light brown, 144°; Cu₂Cl₂2NH₃, dark brown, 162°. Tables are given which show the vapour pressures of the seven compounds at a series of different temperatures.

H. M. D.

Dissociation Pressures of Certain Oxides of Copper, Cobalt, Nickel, and Antimony. Harry W. Foote and E. K. Smith (J. Amer. Chem. Soc., 1908, 30, 1344—1350).—The dissociation pressures of cupric oxide, cuprous oxide, cobalto-cobaltic oxide, cobaltous oxide, nickeloous oxide, and antimony tetroxide have been measured at temperatures between 800° and 1245°. When possible, the temperature has been determined at which the dissociation pressure equals the pressure of the oxygen in the air. Cupric oxide gives this pressure at about 1025°, cobalto-cobaltic oxide at about 905°, and antimony tetroxide at about 950°. The dissociation pressure of cuprous oxide does not exceed 1 mm. at 1020°. Pure cobaltous oxide does not show a dissociation pressure at 1100°.

The dissociation pressures of cupric oxide and nickeloous oxide calculated by Stahl (Metallurgie, 1907, 4, 682) from Nernst’s formula are much lower than those now obtained by direct measurement.

E. G.
Reduction of Fehling's Solution to Metallic Copper. Deposition of Copper Mirrors on Glass. Punchanan Neogi (Zeitsch. anorg. Chem., 1908, 59, 213—215).—To obtain a mirror by reduction of Fehling's solution, the copper sulphate solution is poured into a beaker, the tartrate solution added until the precipitate at first formed just disappears, a considerable amount of formaldehyde is then added, the beaker inclined, and heated on one side until the deposition of copper just begins. On rotating the beaker, a mirror forms all over the inner surface. One of the precipitates thus produced contained 98.6% of copper. G. S.

Oxidation by means of Cuprous Oxide in Strongly Alkaline Solution. Richard Ehrenfeld (Zeitsch. anorg. Chem., 1908, 59, 161—182).—An attempt was made to estimate cupric salts volumetrically by reducing them completely to the cuprous form by the action of an arsenite in strongly alkaline solution, the excess of arsenite being determined by titration with iodine, but the results came out about 6% too high. This result is due to the simultaneous oxidation of part of the arsenite by the oxygen of the air under the catalytic influence of cuprous oxide.

In the absence of a reducing agent, cuprous oxide in the presence of strong alkali undergoes autoxidation, and more than the theoretical amount of oxygen required for the formation of cupric oxide is absorbed. It is probable that the excess of oxygen goes to the formation of hydrogen peroxide, which is, however, immediately used up in oxidising more cuprous oxide. Autoxidation of cuprous oxide also takes place in the presence of concentrated sulphuric acid, excess of oxygen being absorbed and hydrogen peroxide formed.

Strongly alkaline solutions of antimony trichloride behave exactly like arsenite solutions, and the oxidation of alkaline sodium sulphite and stannous chloride solutions is also accelerated by cuprous oxide. In the latter case, however, only the theoretical volume of oxygen is absorbed. On the other hand, cuprous oxide does not accelerate the oxidation of chromic sulphate, potassium nitrite, potassium phosphite, or potassium hypophosphite in alkaline solution. Potassium phosphite and hypophosphite and sodium sulphite are more readily acted on by the oxygen of the air in aqueous than in strongly alkaline solution.

G. S.

Solubility of Precipitated Basic Copper Carbonate in Solutions of Carbon Dioxide. E. E. Free (J. Amer. Chem. Soc., 1908, 30, 1366—1374).—In connexion with a study of the effect of mine detritus in irrigation waters, it was found necessary to ascertain the solubility of precipitated basic copper carbonate in water containing varying amounts of carbon dioxide, and the influence of certain salts on it. The precipitate obtained on mixing solutions of copper sulphate and sodium carbonate is at first pale bluish-green, but gradually loses carbon dioxide and becomes of a malachite-green colour. The latter product is regarded by Gröger (Abstr., 1900, ii, 542) as the compound $6CuO,3CO_2,4H_2O$. It has now been found that the substance is of variable composition, and is so changed by the
action of carbon dioxide and water that it gradually becomes less soluble in the carbon dioxide solution. On repeatedly treating such precipitates with solution of carbon dioxide of 0.12% strength, they finally reach a constant solubility of about thirty-five parts per million, but the solubility increases with the concentration of the carbon dioxide. The solubilities are but little changed by the addition of small quantities of sodium chloride or sulphate, but are increased by larger amounts of these salts. Sodium and calcium carbonates decrease the solubility greatly, but calcium sulphate does not cause a decided change in either direction.

E. G.

Resolution of Ytterbium into its Components. Georges Urbain (Chem. Zeit., 1908, 32, 730).—The author disputes Welsbach’s claim for priority, and states that the decomposition products, neoytterbium and lutetium, which he obtained (Abstr., 1907, ii, 956) are identical with those of Welsbach, called by him aldebaranum and cassiopeium (this vol., ii, 591).

J. V. E.

Interaction of AluminiumPowder and Carbon. Frank E. Weston and H. Russell Ellis (Trans. Faraday Soc., 1908, 4, 60—71. Compare Fichter, Abstr., 1907, ii, 691).—The interaction of finely-powdered aluminium and finely-powdered wood-charcoal, sugar-charcoal, and graphite has been investigated. In all cases, mixtures could be prepared which, when started with a fuse of magnesium and barium peroxide, reacted with vivid incandescence, like the ordinary thermit reaction. Some mixtures, when raised to a dull red heat in a closed crucible, reacted vigorously on exposure to the air.

In all cases the reaction product contained aluminium carbide, nitride, and oxide, as well as the free elements. As the only hydrocarbon obtained by the action of water or hydrochloric acid on the product is methane, it is probable that the only carbide formed is Al₄C₃.

The authors consider that the air plays a prominent part in the phenomenon, that the first action is the oxidation of the carbon to monoxide and dioxide, the heat given out starts the oxidation of the aluminium, and, finally, the latter reaction raises the temperature sufficiently to bring about combination of the aluminium with carbon and nitrogen. Among other reasons in support of this view, it was found that, when the air was withdrawn from the mixtures by means of a Töpler pump, it was much less easy to initiate combination.

G. S.

Corrosion of Iron by Water and Water Solutions. E. Heyn and O. Bauer (Chem. Zentr., 1908, i, 2063—2065; from Mitt. K. Mat.-prüf.-Amt, Gross-Lichterfelde, 1907, 28, 1—104. Compare Friend, this vol., ii, 698).—A. Influence of Oxygen and Carbon Dioxide on the Corrosion of Iron by Water and by Water Solutions.—The rusting was estimated by allowing small, weighed wrought-iron plates to rust when suspended in Charlottenburg conductivity water, or aqueous solutions contained...
in a glass beaker, and re-weighing them after removing the rust. Air was allowed free access to the iron and water; in some cases, it was drawn through the liquid, and the temperature was that of the ordinary room. The results obtained support the conclusions of Traube (Abstr., 1885, 1105) and Dunstan (Trans., 1905, 87, 1548), that carbon dioxide is not needful, but the presence of free oxygen is a necessary condition for the process of rusting; also, that the iron does not derive oxygen from the water, but from the atmosphere. After discussing the conditions that influence the rate of rusting, the authors cite some experiments which show that the addition of hydrogen peroxide does not increase the rate of rusting so much as does drawing air through the liquid in which the iron is suspended.

B. Rusting Influenced by the Iron being in Contact with other Metals.
—Copper when in contact with the iron is found to increase the rusting 25% when suspended in conductivity water and 47% in artificially-prepared sea-water. In contact with nickel, iron rusts 14—19% more than it does by itself, and ingot-iron in contact with cast-iron rusts less readily than when by itself, whilst the cast-iron rusts more readily by about 50%. It is found that iron in contact with a more positive metal, suspended in a liquid causing rusting, rusts less readily, and when in contact with a more negative metal, rusting takes place more readily than when iron is exposed under similar conditions by itself.

—The results show that a content of 0·46 to 3·08% of manganese and 0·072 to 3·38% of phosphorus has very little influence on the rate of rusting.

D. Influence of Various Liquids on the Rusting of Iron at the Ordinary Temperature.—It is found that very dilute solutions of simple electrolytes generally cause iron to rust more slowly than does distilled water alone; with increase of concentration, however, the rusting increases, reaching a maximum and then decreasing slowly. The solutions showing maximum activity are called "critical solutions," and generally cause iron to rust more readily than distilled water. Exceptions to this, however, are solutions of potassium chloride, sodium chloride, potassium sulphate, sodium hydrogen carbonate, sodium sulphate, calcium chloride, and barium chloride, the activity of which is less than that of distilled water. Ammonium nitrate solution and a saturated solution of diammonium hydrogen phosphate cause iron to rust, probably owing to their decomposition, and thus appear to contradict the previous conclusion A; the behaviour of the "critical solution" of diammonium hydrogen phosphate is also abnormal.

In the case of certain salt solutions when the concentration is increased beyond the "critical concentration," the rusting is very rapidly decreased, until a concentration is reached where no rusting takes place; such solutions are called "limiting solutions." Diammonium hydrogen phosphate again behaves in a distinctive manner, having a second limiting concentration, and, finally, in still more concentrated solutions, iron is dissolved with liberation of a gas.

E. Electrical Potential between Iron and Various Liquids.—This section not being suitable for abstraction, the original should be consulted.

J. V. E.
Alloys of Iron, Silicon, and Carbon. W. Gontermann (Zeitsch. anorg. Chem., 1908, 59, 373—413).—The investigation covers that portion of the iron-carbon-silicon system which includes the components Fe—Fe₃C—FeSi. Pure iron-carbon alloys were fused with silicon in porcelain tubes in an atmosphere of purified nitrogen. Repeated melting was sometimes necessary to ensure homogeneity.

Iron containing only 0.7% carbon exhibits a transformation point at 1411°, which appears on both the heating and cooling curves, and does not disappear on re-heating, but is absent from alloys containing even a slightly larger proportion of carbon. Owing to undercooling, alloys containing 3—4% C may contain both structurally-free martensite and cementite. A hypothetical equilibrium curve is suggested for the iron-carbon alloys, assuming the existence of two immiscible liquid phases above 3—4% C, one of which readily sets free graphite. The behaviour of white and grey cast-irons may be explained on this assumption. The transformation observed at 800° may be the eutectoid point of β-iron and graphite. Slight modifications are also suggested in the iron-silicon diagram (compare Guertler and Tamman, Abstr., 1906, ii, 32).

The ternary equilibrium is represented by projections on the base of the space-model. The freezing points lie on two surfaces, on one of which an Fe—C—Si solid solution separates (silicon-martensite), and on the other an Fe₃C—FeSi solid solution (silicon-cementite), the two intersecting along a eutectic line. At lower temperatures, the stable system consists of silicon-ferrite and graphite, but the reaction is slow and the development of heat very small, so that the exact position of the curve of separation of graphite could not be determined. The only part of the metastable system which could be satisfactorily followed was the eutectoid line between silicon-ferrite and silicon-cementite (silicon-pearlite). Alloys consisting of unsaturated silicon-martensite undergo the metastable change on cooling under the conditions adopted, whilst saturated silicon-martensite, or a mixture of this with silicon-cementite, sets free graphite (stable change) if the silicon-content exceeds 1%. Silicon-cementite containing more than 20% Si does not undergo transformation in the solid state.

C. H. D.

The Thomas Steel Process. F. Wust and L. Laval (Metallurgie, 1908, 5, 431—462, 471—489).—The relative rate of oxidation of the various elements present in pig-iron during the Thomas basic steel process has been studied experimentally. From 8 to 10% of iron is lost during oxidation, mostly during the last stage of the process, when the last traces of phosphorus are being removed. This increases with rise of temperature, the tendency of iron to oxidise increasing more rapidly with temperature than that of phosphorus. The conditions are not altered by drying or heating the air supply. Curves are given showing the change in composition of metal and slag during the process.

The changes in structure of the alloys are illustrated by photomicrographs. The original phosho-rectic iron contains crystals of cementite and martensite and a ternary cementite-martensite-phosphide
eutectic, as well as well-formed crystals of sulphide. With progressive elimination of carbon, the ternary eutectic is replaced by a binary martensite-phosphide eutectic. C. H. D.

Dissociation Pressures of Ferric Oxide. Percy T. Walden (J. Amer. Chem. Soc., 1908, 30, 1350—1355).—Determinations of the dissociation pressures of ferric oxide have been made at temperatures between 1100° and 1400°. At 1350°, the pressure is approximately equal to that of the oxygen in the air. Ferrosferric oxide does not show any dissociation pressure at 1350°.

By heating cuprous oxide with ferric oxide, Stahl (Metallurgie, 1907, 4, 688) obtained a strongly magnetic product, and concluded that the following reaction had occurred: Cu₂O + 3Fe₂O₃ = 2CuO + 2Fe₃O₄. It is now shown that this magnetic substance was probably the compound CuFe₂O₄ described by List (Abstr., 1879, 13). It is probable that there is another magnetic double oxide of iron and copper which has not yet been described, and work on this and similar substances is in progress.

Ferrinitrososulphides. Livio Cambi (Atti R. Accad. Lincei, 1908, [v], 720—724).—A theoretical paper in which facts already abstracted (Abstr., 1907, ii, 960; this vol., ii, 41, 288) are discussed at length with particular reference to the views of Bellucci and Cesaris (Abstr., 1907, ii, 29, 472; this vol., ii, 111, 499, 593).

W. A. D.

Gases Occluded in a Special Nickel Steel. G. Belloc (Compt. rend., 1908, 147, 244—245. Compare this vol., ii, 108).—The proportion and nature of the gases occluded by a nickel steel containing about 45% of nickel and 0.15% of carbon have been determined by the method described previously. The occluded gases consist of carbon monoxide and dioxide, hydrogen, and nitrogen, the first being completely evolved below 520°, whilst the last only commences to be evolved above this temperature. Different results are obtained according as the steel is in the form of wire or shavings. In the latter case, the total gas evolved is 3.5 times the volume of the alloy; the curve obtained by plotting the variation of the volume of the gas evolved with the temperature (dv/dt) against the temperature (t) is sensibly parallel to the temperature axis, and the proportion of carbon monoxide increases up to 75%, whilst the maximum amount of hydrogen is evolved at 540°, above which the volume of hydrogen produced gradually decreases. With the wire the total volume of gas evolved is ten times that of the metal; the curve (in t, dv/dt) exhibits well-defined maxima at 540° and 830°, and the variations in composition of the gas are no longer gradual; thus at 540° a minimum proportion of carbon monoxide and a maximum of hydrogen are observed, whilst above this temperature the carbon monoxide increases somewhat irregularly. The mean proportion of hydrogen is greater than from the shavings.

This alloy belongs to the type termed by Guillaume "reversible," the limits of its gradual transformation being 350° and 400°. The greater part of the gases is evolved while the iron is in the γ-state and
the nickel in the β-state, from which would be expected a gradual alteration in the composition and volume of the gas evolved. The latter is the case with shavings, and the different behaviour of the wire indicates an alteration in its molecular state. The difference in absolute volumes of the gas evolved from shavings and from wire can be explained either by (1) unequal distribution in the ingot, or (2) large mechanical loss of occluded gas in turning, or (3) absorption of gas during the manufacture of the wire.

E. H.

Action of Arsenic Chloride and Arsenic on Cobalt. F. Ducelliez (Compt. rend., 1908, 147, 424—426).—By the action of arsenic chloride, metallic cobalt is transformed into a mixture of chloride and arsenide, the composition of the latter ranging from CoAs₂ to Co₃As₂ according as the temperature of the reaction is increased. When mixtures of arsenic chloride with cobalt or alloys of arsenic and cobalt, or mixtures of arsenic and cobalt (both components being powdered), are heated in an inert atmosphere (hydrogen or carbon monoxide), or when powdered cobalt is heated in a current of hydrogen containing arsenic vapour, the following results are obtained. Between 800° and 1400°, tricobalt diarsenide, Co₃As₂, is formed, and above 1000° is obtained as brilliant ingots, D° 7.82, which lose arsenic about 1400°. From 600° to 800°, cobalt or the arsenide, Co₃As₂, is converted into cobalt arsenide, CoAs, a grey, crystalline powder, D° 7.62, which tarnishes slightly in the air, and when heated in a current of hydrogen commences to lose arsenic at 800° without melting. At 400—600°, the final product contains 65.6% of arsenic corresponding with the composition Co₂As₃; it has D° 7.35, and commences to decompose at 600°. Below 400°, the preceding compound is slowly transformed into smaltine, CoAs₂, which is not directly obtained at these temperatures by the action of arsenic trichloride on cobalt. The product is a grey powder, D° 6.97, oxidised by the air, and decomposed slightly above 400°. In the experiments above 600°, a little arsenic is set free, the amount increasing with the temperature. In the first two series of experiments, after the arsenide is formed, continued action of arsenic chloride results in the formation of cobalt chloride and liberation of arsenic, the weight of the compound diminishing. In the last two cases, arsenic is not deposited or cobalt chloride formed after the production of Co₂As₃ or CoAs₂.

The compound Co₃As₂ can also be prepared by reducing cobalt arsenate or arsenite with hydrogen at 900°; the heat developed, volatilising part of the arsenic, prevents the formation of cobalt arsenide, CoAs.

The arsenides described are non-magnetic, and their densities are much higher than those found by calculation for mixtures. They are violently attacked by chlorine, oxygen, and sulphur, readily dissolved by nitric acid and aqua regia, and slowly attacked by fused alkalis and alkali carbonates, but hot concentrated hydrochloric acid has very little action, and sulphuric acid still less.

E. H.

of mixtures of the metals have been obtained and the micro-structure of the solidified products examined.

Cobalt and tin are miscible in all proportions in the liquid condition. The compounds Co₅Sn, m. p. 1151°, and CoSn, which melts with decomposition at 943° and undergoes a polymorphic change at 526°, are formed. In the solid condition, the maximum amount of tin dissolved by cobalt is 3-5%.

Cobalt and antimony are completely miscible in the liquid state. The compounds CoSb, m. p. 1191°, and CoSb₂, which melts with decomposition at 879-5°, are formed. In the solid state, antimony is soluble to the extent of 12-5% in cobalt.

Cobalt and lead are partly miscible in the liquid state; molten alloys containing more than 3% or less than 99% of cobalt cannot be obtained. Neither compounds nor mixed crystals are formed in the solid state.

The behaviour of cobalt and bismuth is similar to that of cobalt and lead, the limits of miscibility in the liquid state being represented respectively by 6% and 93% of cobalt.

Cobalt and thallium are only slightly miscible both in the liquid and solid state, and there is no evidence of the formation of definite compounds.

Cobalt and zinc yield mixed crystals when the percentage of cobalt in the fused mass varies from 0-5 to 18-5. The saturated mixed crystals contain 13-4% cobalt. Evidence has also been obtained of the formation of a compound CoZn₄.

Cobalt and chromium are miscible in all proportions both in the liquid and solid state. The minimum temperature at which crystallisation commences is about 1320°, the composition of the fused mass corresponding with 47% chromium. Alloys containing from 30—100% chromium undergo a change of structure at 1226°. The homogeneous mixed crystals which are primarily formed in the cooling process are transformed at this temperature into two different kinds of crystals, which are readily distinguished after electrolytic etching.

Cobalt and silicon are completely miscible in the liquid condition. In the solid state, the miscibility is confined to alloys containing less than 7-5% or more than 91% silicon. Five compounds are formed: Co₂Si, m. p. 1327°; CoSi, m. p. 1393°; CoSi₂, m. p. 1277°; CoSi₃, m. p. 1307°, and Co₃Si, which is formed in the solid state from the compounds Co₂Si and CoSi.

Measurements of the magnetic permeability of the alloys and the temperatures at which the magnetic qualities undergo changes have been made.

The paper concludes with a discussion of the relationships between the metals iron, cobalt, and nickel on the basis of the freezing-point diagrams of their principal alloys. A table is given showing the miscibility in the liquid states and the compounds formed in each case. The data show that in the liquid as well as in the solid state, the miscibility of nickel with other metals is greater than that of cobalt, which in its turn is greater than that of iron. Nickel also yields the greatest number of compounds, and iron the smallest number.
Cobalt-Tin Alloys. S. F. Schemtschuschiny and S. W. Belynsky (Zeitsch. anorg. Chem., 1908, 59, 384—370. Compare Lewkonja, preceding abstract).—The alloys formed by cobalt and tin have been studied by an investigation of the cooling curves of molten mixtures containing different proportions of the two metals, and an examination of the micro-structure of the solidified products. The freezing-point diagram, constructed from the experimental data, shows the existence of five curves. Two compounds, $Co_2Sn$ and $CoSn$, are indicated. The former corresponds with a maximum freezing temperature of 1171°, the latter being characterised by a transition point at 927°. Above 515°, $CoSn$ separates out in $\alpha$-crystals, and below in $\beta$-crystals. The curves for the compounds are limited by eutectic points at 229° and 1112°. The eutectic alloy corresponding with 229° contains less than 1 atom % of cobalt, and that corresponding with 1112°, 79·5 atom % of cobalt. The two compounds are much harder than either of the components. The compound $Co_2Sn$ is magnetic; $CoSn$ has no magnetic properties either in the $\alpha$- or the $\beta$-modification.

H. M. D.

Phosphorus Compounds of Nickel. N. Konstantinoff (J. Russ. Phys. Chem. Soc., 1908, 40, 742—752).—The freezing-point curve of nickel-phosphorus alloys indicates that, when melted together, nickel and phosphorus form the compounds $Ni_2P_2$ and $Ni_3P$, the former of which exists in two modifications; the $\beta$-form, which is stable at high temperatures, is transformed into the $\alpha$-form at 1025°. At lower temperatures there exist also the compound $NiP$, and another, richer in phosphorus than $Ni_2P$. With $Ni_2P$, the $\beta$-modification of $Ni_2P_2$ forms solid solutions, the limiting concentration of which corresponds with about 18% of phosphorus by weight (29·5 atomic %). These solid solutions decompose into the $\alpha$-form of $Ni_5P_2$ and $Ni_3P$ at 1000°.

T. H. P.

Action of Arsenic Trichloride on Nickel and the Arsenic-nickels. Emile Vigouroux (Compt. rend., 1908, 147, 426—428).—Powdered reduced nickel, when heated in arsenic chloride vapour, is not attacked below 400°. Between 400° and 600°, it is converted into nickel chloride and a compound having a composition corresponding with $NiAs$. The same compound is formed at 600° to 800°, but at 800—1400° the product consists of $Ni_5As_3$.

By heating a mixture of powdered nickel and arsenic in an atmosphere of hydrogen, or by heating the metal in arsenic vapour, a series of arsenic-nickels is readily obtained. These contain, when prepared at 300—400°, 72% of arsenic; at 400—600°, 65% of arsenic; at 600—800°, 56% of arsenic; above 800°, 46% of arsenic, whilst an arsenide containing 39% of arsenic is obtained by treating alloys containing 11—38% with dilute sulphuric acid and separating with a magnet. On heating with arsenic chloride vapour, these arsenic-nickels tend to form $NiAs$ at 400—800° by absorption or loss of arsenic, whilst at 800—1400° the resulting compound is $Ni_3As_2$.

The arsenide $NiAs$, identical with the natural nickeline, has a red
colour, and, according to the temperature of preparation, is obtained as a powder, composed of small crystals with a metallic lustre, or as a slightly fritted mass, D° 7·57.

The arsenide Ni₃As₂ (also obtained by Wöhler, Ann. Chim. Phys., 1832, [ii], 51, 208; by Descamps, Abstr., 1878, 705, and by Granger and Didier, Abstr., 1900, ii, 349) is a grey, pulverulent substance with a metallic lustre, which melts at 1000°, giving a hard, brilliant silver-white ingot, which readily breaks into lamellae, D° 7·86.

The arsenide NiAs commences to lose arsenic at 100°, being converted into Ni₃As₂, which is very stable, and is only slightly decomposed at 1400°. Conversely, when heated in an atmosphere of hydrogen at decreasing temperatures in the presence of arsenic, these two compounds absorb the latter, giving, finally, below 400° a grey powder having the composition NiAs₂, identical with rammelsbergite.

The arsenides are attacked by heated chlorine, oxygen, or sulphur vapour. They are rapidly dissolved by nitric acid and aqua regia, are very slightly attacked by hydrochloric and sulphuric acids, are decomposed by fused potassium chloride and nitrate, but are only slowly attacked by alkalis or alkali carbonates.

E. H.

Some Alloys of Chromium and Manganese. G. HINDRICH (Zeitsch. anorg. Chem., 1908, 59, 414—449).—Aluminothermic chromium and aluminium were used. Chromium is very viscous at its melting point, and requires to be heated more strongly to yield uniform alloys; magnesia crucibles are therefore necessary. When a carbon electric furnace is used, some carbon is always absorbed by the chromium, owing to the passage of gas through the porous magnesia.

The freezing point of chromium (1550°) is lowered by the addition of tin up to 10% mixed crystals being formed up to 6% Sn. Beyond this, two liquid layers are formed, one of which is practically pure tin.

Chromium and copper are only miscible to a small extent in the liquid state, but the emulsion formed does not separate readily into two layers.

Liquid chromium and silver are also only partly miscible. The addition of 5% Ag lowers the freezing point of chromium by 50°. Solid solutions are not formed.

Molten zinc dissolves chromium to some extent; molten cadmium not at all.

The addition of 27% of lead lowers the freezing point of chromium by 80°; alloys richer in lead separate into two layers, one of which is pure lead.

The preparation of alloys of chromium and aluminium is difficult, owing to oxidation and to the action of aluminium on the magnesia crucible at the high temperature necessary. It is better to prepare them by the ignition of a mixture of aluminium, chromium oxide, and potassium dichromate. Between 5% and 55% Cr, the liquid forms two layers, and there appears to be a compound of the formula Cr₄Al, the melting point of which lies much above 1600°.
Manganese and silver form immiscible liquids from 30\% to 90\% Mn, and do not form solid solutions.

Manganese and aluminium form two compounds, probably Mn$_3$Al and MnAl$_3$, both of which form mixed crystals. Alloys containing between 57\% and 86\% Al separate into two liquid layers.

Tammann's rule (Abstr., 1907, ii, 445) is confirmed, that the element with the higher m. p. takes up more of that with the lower m. p. to form mixed crystals than conversely.

C. H. D.

**Sodium Chromisilicates.** Zygmunt Weyberg (Centr. Min., 1908, 519—523).—By fusing a mixture of silica, sodium carbonate, and chromic oxide with a large excess of sodium chloride, a dark green, crystalline powder having the composition

\[ 6\text{SiO}_2\cdot 3\text{Cr}_2\text{O}_3\cdot 2\text{Na}_2\text{O} \]

was obtained; the crystals are orthorhombic and strongly pleochroic. A mixture of sodium metasilicate, chromic hydroxide, and excess of sodium chloride gave rhombic crystals with the composition

\[ 11\text{SiO}_2\cdot 2\text{Cr}_2\text{O}_3\cdot 6\text{Na}_2\text{O} \]

and a mixture of ammonium dichromate, sodium metasilicate, and sodium chloride gave the product 95\%\text{SiO}_2\cdot 2\text{Cr}_2\text{O}_3\cdot 3\text{Na}_2\text{O} in tridymite-like crystals.

The compounds obtained when chromium takes the place of aluminium or iron in these experiments are thus of quite a different type (Abstr., 1906, ii, 23, 91, 865). When the sodium salts are replaced by salts of other alkali or alkaline earth metals, no definite results were obtained. With lithium salts, olivine-like crystals of lithium ortho-silicate, Li$_4$SiO$_4$, were formed.

L. J. S.

**Treatment of Pitchblende Residue.** Ludwig Haitinger and Karl Ulrich (Monatsh., 1908, 29, 485—496).—The paper deals with the working up of the radioactive residue (10,000 kilograms) from 30,000 kilograms of pitchblende containing 53.4\% U$_3$O$_8$. The operations, which occupied two years, are the following: The residue is heated for a working day with half its weight of sodium hydroxide (25\% solution). After washing away the greater part of the soluble sulphates, the residue is digested on the water-bath with one and a-half times its weight of hydrochloric acid (1:1), and then washed with water. The hydrochloric acid extract is practically free from radium, but contains the bismuth-polonium and the actinium. The residue is next heated with half its weight of sodium carbonate (25\% solution, free from sulphate), whereby a great part of the radium sulphate is converted into the carbonate; the mass is washed until free from soluble sulphates, and treated with pure hydrochloric acid. After three such treatments with sodium carbonate, &c., the final residue is practically free from radium, as also are the sodium carbonate extracts and the aqueous washings. The hydrochloric acid extracts, containing all the radium, are treated with sulphuric acid; the precipitated sulphates of lead, metals of the alkaline earths, and of the rare earths in the form of double sulphates, are heated repeatedly with an excess of concentrated sodium carbonate. The conversion of the sulphates into the carbonates is never complete, and therefore, after extracting
the mass with hydrochloric acid, the residue is boiled with water to remove the lead chloride (which is purified by recrystallisation and utilised for the preparation of radioactive lead) and then added to the next batch of crude sulphates. The hydrochloric acid solution, containing the radium, is freed from lead by hydrogen sulphide, evaporated to dryness, and the greater part of the calcium chloride extracted by concentrated hydrochloric acid. The resulting crude chloride, containing radium and barium, and also strontium, calcium, and small amounts of other substances, weighs 20 kilograms in a moist state; the least soluble constituent is the radium chloride. By repeated fractionation, it is separated into two parts, one (2 kilograms) containing nearly all the radium, and the other (11 kilograms) containing very little. The smaller part is again fractionated until the first crop of crystals is reduced to 9 grams. This crop is dissolved, freed from a little impurity by hydrogen sulphide, and separated in silica vessels into four subsidiary fractions and one "final" fraction, on which a determination of the atomic weight, by Richard's method for barium, gave the value 225, whilst the activity number was $27.2 \times 10^6$. The activity numbers of the four subsidiary fractions are $17.0 \times 10^6$, $6.1 \times 10^6$, $2.5 \times 10^6$, and $3.1 \times 10^6$ respectively. The total calculated amount of radium corresponds with 3.236 grams of anhydrous radium chloride of activity $27.2 \times 10^6$.

A portion of the crude barium was converted into the bromide, from which a "final" fraction of radium bromide was obtained. It weighed 0.5 gram, and after a year the weight had decreased to 0.389 gram. It was examined by Brill, who found that it lost 5.4% in weight when heated, gained 17.2% when heated in a current of hydrogen bromide, and contained 0.1792 gram of radium. The fact that radium bromide loses bromine by keeping is not generally known.

C. S.

Physicochemical Researches on Tin. VII. Ernst Cohen (Zeitsch physikal. Chem., 1908, 63, 625—634. Compare Abstr., 1900, ii, 83, 212, 408; 1901, ii, 106, 244; 1904, ii, 567; 1905, ii, 168).—Since the publication of the author's earlier papers, numerous cases of the corrosion of coins, organ-pipes, and other articles made of tin, due to partial conversion into the grey modification, have come to light. Photographs of a number of these articles are reproduced.

A large quantity of grey tin having been put at the disposal of the author, the transition temperature has been determined with greater accuracy than heretofore. It is found to lie very close to 18°.

J. C. P.

An Alloy of Thorium and Nickel. Édouard Chauvenet (Bull. Acad. roy. Belg., 1908, 684—685).—Moissan and Hönigschmidt (Abstr., 1906, ii, 678), attempting to prepare metallic thorium by reducing potassium thorium chloride or thorium chloride with metallic sodium, obtained a metal containing 10—25% of thorium. The author, using lithium instead of sodium, and heating in a nickel boat, failed to prepare pure thorium, but obtained an alloy of thorium and nickel in the form of either grey lamellae or a black pyrophoric powder. The analysis of this agrees with the formula $\text{Th}_2\text{Ni}$. The alloy in-
variably contains 10% of thorium oxide. The pyrophoric variety inflames spontaneously either when powdered in a mortar or when dried in an oven at 115°. It does not give nickel carbonyl when heated in carbon monoxide at 60°, whilst at 400° the gas is decomposed with depositions of carbon. The alloy is non-magnetic, and is rapidly dissolved by hydrochloric acid.

E. H.

Rapid Preparation of Antimony Pentasulphide (Golden Sulphide). Albert Sartorius (Chem. Zentr., 1908, i, 2130—2131; from Apoth. Zeit., 1908, 23, 342—343).—The usual method of preparing Schlippe’s salt is to boil antimony trisulphide and sulphur with sodium hydroxide one and a-half to two hours, when, theoretically, sodium sulphantimonate and sodium meta-antimonate should be formed. If, however, the process is stopped after one-quarter of an hour’s boiling, it is found that scarcely any of the antimony trisulphide has been acted on, the reaction that takes place being expressed by

\[ 6\text{NaOH} + 4S = 2\text{Na}_2\text{S} + \text{Na}_2\text{S}_2\text{O}_3 + 3\text{H}_2\text{O}. \]

To avoid this formation of thiosulphate, the author adds the mixture of antimony trisulphide and sulphur to the boiling sodium hydroxide solution, in small portions at a time. Under these conditions, the reaction proceeds according to the following equation: 

\[ 4(\text{Sb}_2\text{S}_3 + 2\text{S}) + 18\text{NaOH} = 5\text{Na}_3\text{SbS}_4 + 3\text{NaSbO}_3 + 9\text{H}_2\text{O}, \]

and in a shorter time a larger yield of Schlippe salt of a better quality is obtained.

J. V. E.

Thioantimonates of Alkali Metals. II. A. D. Donk (Chem. Weekblad, 1908, 5, 629—645. Compare Donk, this vol., ii, 763).—From mixtures of the corresponding alkali thioantimonates with methyl alcohol and water, the following hydrated salts have been isolated: 

\[ \text{Na}_3\text{SbS}_4\cdot 9\text{H}_2\text{O} \text{ (at 0° and 30°)} \]

and

\[ \text{K}_3\text{SbS}_4\cdot 9\text{H}_2\text{O} \text{ (at 15°)} \]

Similar mixtures of alkali thioantimonates with the corresponding hydroxides and water yielded the following hydrated salts:

\[ \text{Na}_3\text{SbS}_4\cdot 9\text{H}_2\text{O} ; \]

\[ \text{Na}_3\text{SbS}_4\cdot \text{NaOH} \cdot 9\text{H}_2\text{O} ; \text{NaOH} \cdot \text{H}_2\text{O} \text{ (at 30°)} ; \text{K}_3\text{SbS}_4 \cdot 5\text{H}_2\text{O} ; \]

\[ \text{K}_3\text{SbS}_4 \cdot 3\text{H}_2\text{O} ; \text{K}_3\text{SbS}_4 ; \text{K}_3\text{SbS}_4 \cdot \text{KOH} \cdot \text{H}_2\text{O} ; \text{KOH} \cdot \text{H}_2\text{O} \text{ (at 30°)} ; \]

\[ \text{(NH}_4)_3\text{SbS}_4 \cdot 4\text{H}_2\text{O} \text{ (at 30°)} ; \text{LiOH} \cdot \text{H}_2\text{O} ; \text{Li}_3\text{SbS}_4 \cdot 10\text{H}_2\text{O} + \text{LiOH} \cdot \text{H}_2\text{O} ; \]

\[ \text{Li}_3\text{SbS}_4 \cdot 10\text{H}_2\text{O} \text{ (at 30°)} . \]

A. J. W.

Dissolution of Metallic Gold in Hydrochloric Acid in Presence of Various Organic Substances. N. D. Averkieff (J. Russ. Phys. Chem. Soc., 1908, 40, 840—859).—Metallic gold dissolves in hydrochloric acid in presence of the following compounds, which are arranged in decreasing order of effectiveness: methyl alcohol, amyl alcohol, chloroform, ethyl alcohol, chloral hydrate, phenol, sucrose, glycerol, trioxymethylene, formaldehyde. The dissolution takes place slowly at the ordinary temperature, but much more rapidly on heating, the time of heating having but little effect on the rate of solution. In some cases it was found that the solution of the gold was accelerated by increasing the amounts of acid and organic substance.

The residues obtained by evaporating these solutions on a water-bath give metallic gold on ignition, the loss on ignition differing from
that observed with \( \text{AuCl}_3, 2\text{H}_2\text{O} \) (loss, 51.6%). Thus, with chloroform, this loss is 45.63; with methyl alcohol, 60.3; with phenol, 65.08; with ethyl alcohol, 78.0; with trioxymethylene, 85.1, and with amyl alcohol, 85.01%.

The results obtained indicate the existence of new compounds and reactions of gold, which are being further studied.  

T. H. P.

**Complex Gold Sulphites.** Arthur Rosenheim, Julian Hertzmann, and Max Pritze (Zeitsch. anorg. Chem., 1908, 59, 198–202).—Two complex sulphites of tervalent gold, \( \text{K}_5[\text{Au(SO}_3]_4, 5\text{H}_2\text{O} \) and \( \text{Na}_5[\text{Au(SO}_3]_4, 14\text{H}_2\text{O} \), were obtained in slender, deep yellow needles by the action of the corresponding alkali hydrogen sulphites on a solution of auric chloride in just sufficient alkali to form a clear solution. The compounds are stable in cold alkaline solution, but soon decompose in neutral or acid solution. On heating, the yellow alkaline solutions become colourless, and probably contain univalent gold, but no definite compounds could be isolated.

When a concentrated solution of gold chloride is added drop by drop to a solution of ammonium sulphite containing excess of ammonia, and the solution is gently warmed, it becomes colourless, and the compound \( \text{Au}_3(\text{SO}_3)_2, 4\text{NH}_3, 4\text{H}_2\text{O} \), separates in colourless, lustrous leaflets. Similarly, from a solution of potassium sulphite to which excess of ammonia has been added, the compound

\[
\text{Au(SO}_3]_5, 2\text{NH}_3, 2\text{H}_2\text{O}
\]

is obtained in colourless needles. The constitution of these two compounds has not been established.  

G. S.

**Nature of Palladium-Lead Alloys.** Nicolai A. Pushin and N. P. Pashsky (J. Russ. Phys. Chem. Soc., 1908, 40, 826–829).—The authors have prepared a number of alloys of palladium and lead by melting the metals in a mixture of lithium chloride with either potassium chloride or barium chloride. The potentials of the various alloys were measured by means of a \( \text{Pb} | N-\text{Pb(NO}_3]_2 | \) alloy element (compare Pushin, Abstr., 1907, ii, 325). All the alloys containing less than 33% (atom.) of palladium have a potential practically identical with that of pure lead, whilst those containing more than 33% (atom.) of palladium give with pure lead a P.D. of more than 600 millivolts. Alloys of the latter class give at first a P.D. of 350–400 millivolts, which, however, increases rapidly at the commencement and more slowly later, approaching asymptotically the value 605–640 millivolts, which value persists for eight to ten hours. The potential of pure palladium also changes in the course of time, the element

\[
\text{Pb} | N-\text{Pb(NO}_3]_2 | \text{Pd}
\]

having at first a P.D. of 760 millivolts; after two hours, the value 880 millivolts is reached, and after a further three hours, this begins to diminish slowly until 600 millivolts is reached. The above results prove clearly the existence of the compound \( \text{Pb}_2\text{Pd} \).  

T. H. P.
Native Tellurium from Asia Minor. Giuseppe Cesàro (Bull. Acad. roy. Belg., 1908, 255—257).—Amongst a series of specimens from the mines of Balia was a large (2 x 3 cm.) dendritic crystal of native tellurium intergrown with quartz. A small proportion of gold is the only impurity present in the material. L. J. S.

Action of Potassium Chlorate on Pyrites and on Hauerite. Giorgio Spezia (Atti. R. Accad. Sci. Torino, 1908, 43, 728—734).—A mixture of pyrites with sufficient potassium chlorate to oxidise between 1 and 2 atoms of the sulphur of the pyrites explodes when brought into contact with either concentrated sulphuric acid or a flame. Under similar conditions, a mixture of sulphur or stibnite with potassium chlorate undergoes rapid combustion, approaching to explosion. With less or more than the above proportion of chlorate, pyrites gives a mixture which does not explode, but undergoes more or less rapid combustion.

The reaction between pyrites and potassium chlorate in the wet way differs, however, greatly from that between sulphur or stibnite and potassium chlorate. When the former mixture, either in explosive proportions or containing an excess of the chlorate, is heated with water, a vigorous reaction begins at 75° and continues without further heating; a yellow deposit forms, chlorine is evolved, and sulphuric acid is detectable in large proportion in the solution. A reaction also takes place very gradually in the cold, but in this case no evolution of chlorine is observed. With potassium chlorate and sulphur or stibnite, no such reaction occurs, and only after protracted heating at 100° is a trace of sulphuric acid formed.

Marcassite behaves with potassium chlorate, in both the wet and dry ways, in the same manner as pyrites, the vigorous reaction in the presence of water commencing at 70°. Hauerite forms an explosive mixture with potassium chlorate, but does not react with it in the presence of water, even at 100°.

When heated, hauerite begins to lose sulphur at about 170°, and is ultimately converted into manganese monosulphide; pyrites, on the other hand, loses sulphur only at about 350°, and gives a compound corresponding with pyrrhotite as final product, the monosulphide only being obtained from pyrites by heating in a current of hydrogen.

From these results, the author concludes that the sulphur present in combination with iron in pyrites has properties different from those of elementary sulphur. T. H. P.

Natural Ferrous Oxide Hydrate. Hart (Chem. Zeit., 1908, 32, 746).—In the clay deposit near Cuxhaven, hard, yellowish-brown lumps have been found among volcanic ash, which crumble when exposed to the air and appear to be ferrous oxide dihydrate, FeO,2H₂O.
Analysis showed 12.55% to be insoluble in hydrochloric acid; the soluble portion had the following composition:

**Origin of the Boric Acid in the Soffioni of Tuscany.**

RAFFAELO NASINI (Atti R. Accad. Lincei, 1908, [v], 17, ii, 43–46).—In a paper read before the Sixth International Congress of Applied Chemistry in Rome (1906) on “The Boraciferous Soffioni and the Boric Acid Industry of Tuscany,” the author referred to a theory put forward by E. Perrone to explain the formation of these soffioni. This theory regards tourmaline as the source of the boric acid. The original temperature of the vapours of the soffioni cannot be less than 250°, and the depth from which they come must be from 5000 to 8000 metres. At this depth there probably exist granitic rocks containing tourmaline, having the characters of the granite found in Elba and elsewhere. The author’s experiments show that when steam at a high temperature is passed over tourmaline extracted from Elba granite and subsequently condensed, the condensed liquid contains boric acid. As, further, this granite exhibits radioactivity, the presence of radioactive gases in the soffioni gases is readily explained.

Objections to this theory raised by D’Achiardi (Atti Soc. toscana sci. nat. Mem., 1907, 23) and Lotti (Rassegna mineraria dell’indust. chim., 1907, 26, No. 14) are discussed.

T. H. P.

**The Wide Distribution of Scandium in the Earth.**

G. EBERHARD (Sitzungsber. K. Akad. Wiss. Berlin, 1908, 851–868).—Although scandium appears to be relatively abundant in the sun and stars, yet it has only rarely been detected in terrestrial materials. Three hundred and sixty-six samples of minerals, rocks, and meteorites of various kinds were examined spectroscopically, and traces of scandium found in a large number of them. It occurs most frequently in zirconium minerals, beryl, titanates, columbates, and titano-columbates of the rare earths, in micas, and in tin and tungsten ores. Wolframite from Zinnwald, Bohemia, contains 0.2% of scandium oxide (\(\text{Sc}_2\text{O}_3\)).

L. J. S.
Existence of a Monoclinic Soda Felspar, Isomorphous with Orthoclase. Philippe Barbier and A. Prost (Bull. Soc. chim., 1908, [iv], 3, 894—899. Compare this vol., ii, 704).—Analyses of seven samples of orthoclase, briefly described in the original, show that orthoclases exist having the potassium partly or wholly replaced by sodium, the latter occurring as a special silicate (not identical with albite) which can ally itself with the orthoclase molecule without causing a change in crystalline form. If orthoclase is represented by the expression $\text{K}_2\text{Al}_2\text{Si}_6\text{O}_{16}$, the sodium compound must be represented as $\text{Na}_2\text{Al}_2\text{Si}_6\text{O}_{16}$.

T. A. H.

Kaersutite from Linosa and Greenland. Henry S. Washington and Fred. Eugene Wright (Amer. J. Sci., 1908, [iv], 26, 187—211).—Crystals of a black basaltic amphibole were collected from the tuff of a small parasitic cone of Monte Rosso, on the small island of Linosa off the coast of Tunis. They are monoclinic, with a prism cleavage angle of 55°22'. Thin sections are brown and strongly pleochroic; the extinction angle is small and in the acute angle $\beta$ (on the prism plane $c': \epsilon = 1^\circ$); the optic axial plane lies in the plane of symmetry, and $2V$ is about 80°. Analysis I shows the mineral to be highly titaniferous, and to be very similar to the kaersutite (of Lorenzen, 1884) from Kaersut, in Greenland. A re-examination and a new analysis (II: 0.77% apatite deducted) were made of the original kaersutite:

T. H. P.

Taramellite, a New Silicate of Iron and Barium. E. Tacconi (Atti R. Accad. Lincei, 1908, [v], 17, i, 810—814; Centr. Min., 1908, 506—508).—The author describes a new mineral, taramellite, occurring
in radiating, fibrous, acicular aggregates or slender veins in the crystalline, calcareous zone of Candoglia-Ornavasso (Val Toce), where it is found in intimate association with magnetite, pyrites, chalcopyrite, paracelsian, pyroxene, and amphibole. It has a reddish-brown colour, a silky or fatty lustre, a hardness of about 5·5, D^17 3·923, n greater than 1·74. The mineral exhibits distinct pleochroism, and has the composition:

\[
\begin{align*}
\text{SiO}_2 & : 86·56 \\
\text{Fe}_2\text{O}_3 & : 21·54 \\
\text{FeO} & : 4·47 \\
\text{BaO} & : 37·32
\end{align*}
\]

together with traces of titanium, aluminium, manganese, and magnesium. The above composition leads to the formula

\[
\text{Ba}_4\text{Fe}^{11}\text{Fe}_4^{11}\text{Si}_{10}\text{O}_{31}
\]

and the mineral may be regarded as a basic salt of a polymeride of metasilicic acid, \(\text{Ba}_4\text{Fe}^{11}\text{Fe}_4^{11}\text{O})\text{Fe}_2(\text{SiO}_8)_{10}\).

T. H. P.

The Zeolites of Montresta (Sardinia). Luciano Pelacani (Atti R. Accad. Lincei, 1908, [v], 17, ii, 66—70).—The zeolites of Montresta include mesolite (anal. I), chabazite (anal. II), heulandite, and stilbite, the first occurring in greatest, and the last in smallest, proportion:

\[
\begin{align*}
\text{SiO}_2 & : 42·94 \\
\text{Al}_2\text{O}_3 & : 25·05 \\
\text{CaO} & : 10·87 \\
\text{Na}_2\text{O} & : 8·12 \\
\text{K}_2\text{O} & : \text{trace} \\
\text{H}_2\text{O} & : 13·32 \\
\text{Total} & : 100·30
\end{align*}
\]

The analyses agree with those of Rimatori (Abstr., 1900, ii, 735). Mesolite is regarded as an isomorphous mixture of scolecite and natrolite, and, from a study of the emission of water on heating, the mesolite of Montresta seems to be more closely allied to scolecite than to natrolite. The amount of water emitted by chabazite when gradually heated to 350° increases more slowly than the temperature rises, whilst with mesolite the reverse is the case. The re-absorption of the water removed by heating to 350° takes place rapidly and completely with chabazite, whilst with mesolite it is slow and only partial. After heating to redness, chabazite absorbs about one-fourth of the total water emitted, whilst mesolite absorbs none at all.

The heulandite has the composition:

\[
\begin{align*}
\text{SiO}_2 & : 57·59 \\
\text{Al}_2\text{O}_3 & : 15·69 \\
\text{CaO} & : 7·62 \\
\text{SrO} & : \text{BaO} \\
\text{Na}_2\text{O} & : 2·87 \\
\text{K}_2\text{O} & : \text{trace} \\
\text{H}_2\text{O} & : 15·77 \\
\text{Total} & : 99·54
\end{align*}
\]

which approximates to that of the heulandite from Berufiord, analysed by Rammelsberg (Zeitsch. deut. geol. Ges., 1869, 21, 93). The stilbite was found only in small quantity, insufficient for analysis. T. H. P.

New Vein of Nephelitic Basalt containing Nosite (Nosean) in Vincentino. L. Maddalena (Atti R. Accad. Lincei, 1908, [v], 17, i, 802—809).—The author has discovered in Vincentino a nephelitic basalt of microporphyritic structure, containing pyroxene, biotite, apatite, magnetite, and nosite, the last being scattered irregularly in
crystals and granules, mostly of hexagonal habit. The basalt has the composition:

<table>
<thead>
<tr>
<th></th>
<th>SiO₂</th>
<th>Al₂O₃</th>
<th>Fe₂O₃</th>
<th>FeO</th>
<th>MnO</th>
<th>CaO</th>
<th>MgO</th>
<th>Na₂O</th>
<th>K₂O</th>
</tr>
</thead>
<tbody>
<tr>
<td>%</td>
<td>31.39</td>
<td>12.15</td>
<td>5.89</td>
<td>6.41</td>
<td>0.41</td>
<td>16.61</td>
<td>9.82</td>
<td>3.48</td>
<td>1.21</td>
</tr>
</tbody>
</table>

which approximates to that of the basalt of Recoaro, the lower proportion of silica in the Vincentino basalt being due to the more advanced condition of alteration of the rock.

Physiological Chemistry.

Regulation of Respiration. F. H. Scott (J. Physiol., 1908, 37, 301—326).—The respiratory mechanism may be stimulated by small amounts of carbon dioxide, or by great diminution of oxygen in the inspired air. These produce increase of both rate and depth of breathing, but if the vagi are divided, the depth increases but not the rate. The alveolar tension of carbon dioxide rises with rise of body temperature; the effect of vagal division on the tension is very variable. Inflation of the lungs even at the height of dyspnœa inhibits inspiration, but if the vagi are divided, it has no effect. The effect of repeated ventilations depends on the washing-out of carbon dioxide from the blood (confirmatory of Haldane). The vagi in reference to respiration are regarded in the same light as the sensory nerves of muscle; without these nerves muscular movements are excessive, and thus resemble those of an ataxic limb.

Heart Perfusion Apparatus. Thomas G. Brodie and Winifred C. Cullis (J. Physiol., 1908, 37, 337—340).—A new apparatus for the perfusion of the isolated mammalian heart is described and figured.

Hæmagglutination and Hæmolysis. Leo von Liedermann (Centr. Bakt. Par., 1908, 47, ii, 372—378).—Polemical and theoretical. Von Eisler (Centr. Bakt. Par., 1908, 46, 353) has attributed to the author the view, that agglutination by ricin is due to the acid nature of this substance, pure and simple. This is a misunderstanding; ricin appears, indeed, to be an acid, but its agglutinant action is a specific property, not shared by other acids, and due to the peculiar physical properties of the ricin-stroma combination (compare Abstr., 1907, ii, 973). In connexion with this, Landsteiner's views are discussed. The inhibitory action of alkali primarily extends to the complement, but also affects the immune substance.
The Time Relations of Hæmolysis on Exposure to Light of Sensitised Red Blood-corpuscles. O. Harzecker and Abl. Jodlbauer (Biochem. Zeitsch., 1908, 12, 306—313).—Suspensions of red blood-corpuscles were submitted to the action of the sensitising substances eosin and sodium dichloroanthracenedisulphonate in the dark, and then exposed to light. The amount of hæmolysis was ascertained by measuring the volume of blood-corpuscles, and of hæmoglobin in the supernatant liquid, in samples of liquid centrifuged after different intervals of exposure to light. It was found in all cases that hæmolysis was a gradual process, and took place at the same rate whether the fluorescing substance was within or both within and without the cell.

S. B. S.

Hæmolysis by Snake Poison. Von Dungern and Coca (Biochem. Zeitsch., 1908, 12, 407—421).—The hæmolytic action of cobra poison depends entirely on the existence of a lipolytic enzyme, by means of which hæmolytically-acting scission products, especially deoleolecithin and oleic acid, are produced. Compounds of lecithin and cobra toxin do not exist; there are no such substances as either saturated or unsaturated toxolecithides. The preparations of Kyes (Abstr., 1907, ii, 569) are mixtures of ferment with deoleolecithin, contaminated with other substances, or their scission products, which are found in commercial lecithin. Cobra poison contains no amboceptors, and the hæmolysis produced by a combination of cobra poison and complement containing serum is due to a complex serum hæmolysin, which acts hæmolytically only under certain conditions, and only when the blood-corpuscles have taken up a certain quantity of lipase.

S. B. S.

Hæmolysis by Soaps, and the Relationship between Soaps and the Complex Hæmolysins of the Blood-serum. Max Friedmann and Fritz Sachs (Biochem. Zeitsch., 1908, 12, 259—277).—Noguchi and von Liebermann have shown that soap can be deprived of its hæmolytic properties by admixture with serum, and have expressed the view that this inactivated mixture acts as a complement, the hæmolytic powers of which can be called into play by the addition of an amboceptor. Such an amboceptor, von Liebermann claims to have discovered in oleic acid, the authors have devised experiments to test the above hypotheses. They have confirmed the fact of the combination between serum and the soap, which is rendered more stable by heating to 70°. They have, however, been unable to confirm the hypotheses as to the complement nature of this combination, or of the amboceptor-nature of oleic acid. The activation of the amboceptor by the addition of the soap-serum mixture, they ascribed to the action of a true serum complement contained in the sera, which had not been entirely destroyed by heating to 50°. The supposed amboceptor action of oleic acid they ascribed to the additive action of the acid and of the soap-serum mixture, each of which was, by itself, unable to produce hæmolysis.

S. B. S.

Hæmolysis by Soaps. Fritz Sachs (Biochem. Zeitsh., 1908, 12, 278—289).—Although soaps can be deprived of their hæmolytic power
by previous admixture with serum, the latter can accelerate their action if the soaps be added first to the suspension of corpuscles. Serum can also accelerate in a like manner, the haemolytic action of oleic acid, which fact, amongst others, led von Liebermann to ascribe amboceptor functions to this acid. The author has attempted to determine the nature of the substance in serum which accelerates haemolysis by soaps. Serum-albumin is inactive; alkalis markedly accelerate the action. It is not to the alkali, however, that serum owes the accelerating property, for neutralised or dialysed serum still possesses it; furthermore, serum which has been deprived of its proteins loses this property. Serum which has been extracted with ether, gains in the haemolysis-accelerating power. The experiments with alkali render it probable that the concentration of hydroxyl ions influences the haemolysis, and the extraction of serum by ether, in removing the fatty acids from the soaps contained therein, may increase the alkalinity of the serum. The experiments, however, lead to no definite conclusions as to the nature of the haemolysis-accelerating substances in serum.

S. B. S.

The Point of Attack of Photodynamic Substances in Paramoecia. Hermann von Tappeiner [with F. Osthelder and E. Erhardt] (Biochem. Zeitsch., 1908, 12, 290—305).—Paramoecia, which have been treated with eosin in the dark, are no more strongly sensitised than those which have been exposed immediately to the light. The eosin does not appear to possess the property of penetrating the cell; its action in sensitising is entirely at the periphery. Dichloroanthracenedisulphonic acid and methylene-blue, on the other hand, are taken up in active form by the cell in the dark; their point of attack is intracellular; there is evidence, however, in the case of these two substances of a peripheral, in addition to the intracellular, action. As to the nature of the peripheral action, nothing definite can be stated.

S. B. S.

Action of Fluorescent Substances on Red Corpuscles. Hermann von Tappeiner (Biochem. Zeitsch., 1908, 13, 1—23).—Eosin and sodium dichloroanthracenedisulphonate produce in the dark at the room temperature no noteworthy destruction of red corpuscles, and, after removal from the solution, they undergo haemolysis at 59° at the same rate as untreated corpuscles. In the light, however, rapid haemolysis occurs. These substances are therefore taken up by the corpuscles in a form in which they are not sensibilised. This haemolysis is more rapid if the light acts before than after washing of the corpuscles from the fluorescent solution. Whether the action occurs in the interior or on the surface of the corpuscles is discussed; phenosafranine shows both kinds of action; methylene-blue only a surface action.

W. D. H.

Action in the Dark of Fluorescent Substances on Proteins, Toxins, and Ferments, and its Reversibility. T. Kudo and A. R. Jodlbauer Biochem. Zeitsch., 1908, 13, 24—43).—Many fluorescent substances act in the dark on the alexin of serum and on tetanolyisin, inhibiting their specific actions. This is not the case with
all fluorescent substances, and the concentration necessary to produce the effect in the dark is relatively high in comparison with that of those which act photodynamically. Those which act in the dark are considered to be adsorbed, and the action is reversible; the presence of alkali is favourable, whilst that of invertase, inhibits. W. D. H.

Nucleoli of Hydra fusca. C. E. Walker and Alice L. Eembleton (Quart J. Exp. Physiol., 1908, 1, 287—290).—The observations relate to the movements of the nucleoli of the cells of the hydra from the nucleus into the surrounding cell protoplasm. The phenomenon is not related to cell division, but is connected with or dependent on metabolic changes, especially with digestion, since it is seen principally in endoderm cells. A marked change takes place in the staining reactions of the extruded nucleolus, which suggests that it undergoes an important chemical or physical change. W. D. H.

The Death of Leucocytes. The Vacuolation of Leucocytes. H. C. Ross (J. Physiol., 1908, 37, 327—332, 333—336).—Methylene-blue kills cells; it is not until death occurs that the nucleus is stained; this is hastened by heat and alkalis, and delayed by neutral salts. After death, the cytoplasm liquefies, and the granules show Brownian movements; this may be brought about by the absorption of fluid. During life the cytoplasm is a jelly.

Certain spots in leucocytes described by previous observers as centrosomes are droplets of fluid absorbed by the cells, which are suspended in the jelly-like cytoplasm. With the liquefaction of the latter which occurs on death, these droplets disappear. W. D. H.

The Production in vivo and in vitro of Precipitins for Ovalbumin by means of Antigens of a Chemically definite Nature. André Mayer and Georges Schleffer (Compt. rend., 1908, 147, 311—313).—The precipitating serum for egg-albumin, usually produced from the rabbits by repeated injection of egg-albumin into the animal, can also be obtained if the animal is starved for five or six days, and the serum collected when it has lost about one-third of its weight and the urine is markedly acid. The precipitating property also appears after chloroform intoxication, and after the formation of aseptic peritoneal abscesses by turpentine. In every case the serum loses its precipitating property after warming to 60°. It was assumed that precipitating sera were produced by the presence therein of products of tissue degradation. Amongst such products are the fatty acids, and attempts were made to produce precipitating sera by injection of these acids. It was found that the sera of animals which had received repeated injections of propionic, butyric, valeric, hexoic, and oleic acids produced marked precipitins with solutions of egg-white. No precipitants were produced by the injections of oeoic, stearic, palmitic, hydrochloric, lactic, or succinic acids.

The precipitate produced is specific for egg-albumin, and the precipitate is soluble in excess of either of the reacting substances; the serum also loses its precipitating properties on warming to 60°.
Soaps and ethyl esters on injection also produce precipitating sera, but the action is not so marked as in the case of the free acids.

Precipitating sera have also been obtained by adding directly to sera (without injection into animals) fatty acids, soaps, and ethyl esters. In the first case, which yields the most marked results, the precipitating property is only destroyed with difficulty by heating.

S. B. S.

Chemico-physical Studies of Animal Fluids. Ia. Viscosity of Blood-serum of Different Marine and Terrestrial Animals. Filippo Bottazzi (Atti R. Accad. Lincei, 1908, [v], 17, i, 707—717).—Measurements are given of the time of outflow of the blood-serum of different animals from an Ostwald viscosimeter, compared with the values obtained with distilled and sea-water at the same temperatures.

W. A. D.

Chemico-physical Investigations on Animal Liquids. Ib. Viscosity of the Blood-sera of Certain Marine and Terrestrial Animals. Filippo Bottazzi (Atti R. Accad. Lincei, 1908, [v], 17, i, 792—802. Compare preceding abstract).—The classification of marine and terrestrial animals according to the increasing time of efflux of their blood or body-fluid from a viscosimeter does not correspond with the ordinary zoological classification, so that the viscosity of the blood-plasma is not strictly dependent on the degree of organisation of the animal. The viscosity of the body-fluid of the marine invertebrates is only slightly greater than that of sea-water. The blood of cephalopods is distinguished from that of all other animals, vertebrate and invertebrate, by having the greatest viscosity. The viscosity of blood-serum increases with the proportion of colloids (sero-proteins) present.

T. H. P.

Chemico-physical Investigations on Animal Liquids. II. Content of Protein Nitrogen in the Blood-sera of Various Animals. Filippo Bottazzi (Atti R. Accad. Lincei, 1908, [v], 17, ii, 16—26. Compare preceding abstracts).—The author has determined the proportions of nitrogen, precipitable by tannic acid, present in the blood-sera of various animals. The results show that, in this respect, marine and terrestrial animals are divided into four groups: (1) Those having sera or body-fluids containing less than 0.5% of protein nitrogen; this class includes Siphunculi, Aplysia, and probably, also, other low marine invertebrates. (2) Various vertebrates and invertebrates, including decapod crustaceans, birds, frogs, and the Selachii, with content of protein nitrogen varying from 0.52 to 0.67%. (3) Those with 0.8 to 0.9% of protein nitrogen, namely, herbivorous and carnivorous domestic mammals, such as cats, dogs, rabbits, and oxen. (4) Cephalopods, the serum of which contains, on an average, 1.66% of protein nitrogen. For the buffalo, the % of protein nitrogen is 1.3636, and for the pig, 1.230.

On comparing the numbers obtained with the viscosity results (see preceding abstract), it is found that, in general, the content of protein in the liquids examined increases with the viscosity. It is hence con-
cluded that the greater or less viscosity of the blood-plasma is due to the greater or less proportion of proteins present. This result is confirmed by experiments, in which the concentration of proteins in serum is increased artificially.

T. H. P.

Chemico-physical Investigations on Animal Liquids. III. Variations of Electrical Conductivity, Viscosity, and Surface Tension of Blood-serum during Dialysis. FILIPPO BOTTAZZI, G. BUGLIA, and A. JAPPHELLI (Atti R. Accad. Lineeii, 1908, [v], 17, ii, 49—57. Compare preceding abstracts).—The electrical conductivity and surface tension of blood-serum diminish considerably during dialysis, the diminution being at first rapid and afterwards slow; the same is the case when the serum is filtered before the conductivity or surface tension is measured. The viscosity of the serum diminishes if the liquid is filtered before determining the time of efflux; here, too, a slight increase in the time of efflux is observable at the beginning of the dialysis. The diminution of the conductivity is evidently due to the diffusion of the electrolytes, and this also causes the precipitation of the sero-globulin.

T. H. P.

Action of Manganese and Iron Sulphates on Diastatic Ferments. ALFRED GIGNON and T. ROSENBERG (Chem. Zentr., 1908, ii, 84; from Skand. Arch. Physiol., 1908, 20, 423—431).—A 1—2% solution of starch and a small quantity of manganese or iron sulphate were added to a freshly-prepared blood-serum, and the amount of sugar estimated by the polarimeter. The presence of these salts undoubtedly increases the amylolytic action of the blood-serum diastase, and is also favourable to the amylolytic ferment of the pancreatic juice.

J. V. E.

XVII.—If proteins, such as gelatin or histone (from the thymus), which are rich in bases are given, the products of digestion in the
jejunum and ileum contain only small amounts of free arginine. The chief substances obtained in the material issuing from the fistula are complexes which are precipitable by tannin. Absorption of gelatin occurs chiefly in the lower parts of the small intestine, and at the end of that tube it is fairly complete.

XVIII.—Details are given of the rate with which the stomach empties itself in dogs; this probably runs pari passu with the rate of digestion. Outside psychical influences do not affect this, but if the food is given by the mouth, it is much accelerated, probably because the normal reflexes due to taste impulses are set in motion.

XIX.—In flesh-feeding (200 grams), the total quantity of chyme which passes the various sections of the intestine decreases with each hour of the digestion period. The intervals between the peristaltic propulsions of the chyme are diminished by removal of the pylorus. The chyme is always a thick fluid, although its chemical and physical characters vary as it passes along; it also varies in the concentration of the digestion products in different segments of the intestine.

XX.—An attempt is made to construct mathematical formulae to show the relationships between the digested, undigested, and absorbed portions of the food in relation to its quantity and the quantity of juices secreted. The experiments on which these are based were made with gliadin as the food.

XXI.—Similar experiments with white of egg; although this is more difficult to digest than gliadin, the same general laws are stated to hold.

XXII.—Loss of blood delays digestion; loss of one-third of the total volume of blood stops it for three hours; during this time the fall of blood-pressure persists. The quality of the blood is also important; in hydramia there is diminution of gastric activity.

XXIII.—Starch, dextrin, sucrose, and dextrose are not absorbed in the dog’s stomach in any concentration, whether dissolved in water or alcohol. Of these carbohydrates, only sucrose and erythro-dextrin undergo slight fission (2—4%) in the stomach, and this is due to the acid, not to enzymes; still large quantities of gastric juice are secreted. No formation of lactic acid was observed. In the duodenum, the carbohydrates undergo fission, the amount of which stated numerically varies in the case of different carbohydrates. Absorption has its main seat in the jejunum and upper ileum; again, the amount is stated numerically. Absorption is completed in the lower ileum; this is usually 100%, or nearly that. Only in the case of dry starch does any important amount (22%) pass through into the large intestine. The intestinal juice appears to be the main agent in the fission of carbohydrates; in starch digestion, however, the duodenal juice is of special importance. This intestinal activity leads to an increase of nitrogenous metabolism, which chiefly shows itself in the secretion of nitrogenous substances into the intestinal lumen.

XXIV.—The fission of emulsified fat begins in the dog’s stomach soon after feeding, and reaches about 32%. This is partly due to gastric lipase, and partly to regurgitated duodenal contents. The pancreatic juice in the duodenum acts vigorously, cleaving 41% of the fat. Below this in the small intestine the percentage of free fatty
acids reaches its maximum, this in some portions reaching 95%; 69% of the fatty acids are still present in the large intestine.

XXV.—The main protein constituent of the tubercle bacillus approaches in composition those proteins with a mean percentage of diamino-acids. In the upper segments of the alimentary tract, it is digested, and it is absorbed throughout the length of the intestinal canal. In the lower ileum very little digestion of this protein takes place.

Gastric Digestion in Fishes. M. van Herwerden (Zeitsch. physiol. Chem., 1908, 56, 453—494).—This investigation definitely proves that the acid of the gastric juice in Selachian fishes is hydrochloric acid. An unimportant amount of formic acid is also present. The results in teleostean fishes are not so clear, mainly owing to the difficulty of collecting the juice during life. During digestion in selachians, the percentage of the acid may rise to 0·4. The proteolytic ferment present is probably pepsin, although some digestion may occur in a neutral medium, and in some teleostean fishes even in an alkaline medium. The acid is secreted at the cardiac region only of the stomach, but the epithelium differs from that seen in higher vertebrates. An amylolytic ferment is absent, but lipase is present.

Influence of Bromine on Gastric Secretion. Togami (Biochem. Zeitsch., 1908, 13, 112—120).—Experiments on dogs with a Pawloff’s “small stomach” show that aqueous solutions of bromine (in contradistinction to iodine) paralyse the stomach glands without any preliminary stimulation. Sodium bromide and bromo-protein compounds act, but not so constantly, in the same direction.

[Importance of Calcium Salts for the Growing Organism]. Arnold Orgler (Biochem. Zeitsch., 1908, 12, 334—335. Compare this vol., ii, 606).—Explanation of a misunderstanding of the meaning of the term “balance” in a work by Aron and his collaborators (this vol., ii, 208), and criticised by the writer of the note. S. B. S.

Behaviour of Lecithin with Bile Salts, and the Occurrence of Lecithin in Bile. John H. Long and Frank Gephart (J. Amer. Chem. Soc., 1908, 30, 1312—1319).—Some authors have stated that bile contains small quantities of lecithin, whilst others have expressed the opinion that this substance is absent. Hammarsten (Abstr., 1901, ii, 520; 1903, ii, 86; 1904, ii, 831), whilst leaving the universal occurrence of lecithin in bile an open question, asserts that it is present in the bile of the polar bear.

Experiments have now been made with ox bile and with human bile, but lecithin could not be separated. It has been found that the bile salts, as usually obtained, carry down a phosphorus complex, which has been regarded by Hammarsten and others as a lecithin. This complex could not be completely removed from the bile salts, as the latter retain it very tenaciously.
Bile salts are capable of dissolving 80% of their weight of egg-lecithin, and much of this can be precipitated with acetone, but a small quantity remains with the bile salts, and is probably much greater than that contained in any bile. The addition of inorganic salts hastens the solution of lecithin by bile salts, but does not increase the amount dissolved. A few inorganic salts, however, such as aluminium and ferric chlorides and lead nitrate, cause the precipitation of the bile acids. When lecithin is dissolved in bile salts, the optical activity is increased, whence it is calculated that the lecithin has \([\alpha]_b + 7.75^\circ\).

**E. G.**

**Action of Acids and Rennet on Human Milk.** *Engel* (*Biochem. Zeitsch.*, 1908, 13, 89—111).—Hydrochloric, lactic, oxalic, and sulphuric acids precipitate human milk, and the optimal acidity is 2—3 c.c. of \(N/10\) acid to 10 c.c. of milk. Phosphoric and acetic acids act best at a greater concentration (5 c.c.); the substance precipitated is caseinogen; rennet precipitates a calcium compound of this protein, and the amount necessary varies within wide limits, but the precipitation is most complete when combined with the optimal concentration of acid.

**W. D. H.**

**Fat and Ester Hydrolysis in Tissues.** *Paul Saxl* (*Biochem. Zeitsch.*, 1908, 12, 343—360).—In organs containing only their own fat, or with additional added neutral fat, only a small amount of fat hydrolysis takes place during autolysis with exclusion of bacterial action. In the case of the addition of monoacetin, monobutyrin, and ethyl butyrate to organs, the increase of acidity after twenty-four to forty-eight hours is due, at any rate partly, to the formation of acid products of autolysis. Amyl salicylate is, however, hydrolysed by all the organs investigated, with the exception of muscular tissue. The power of ester hydrolysis generally is smaller in the case of the muscles than in all other organs. The hydrolysing power of blood-serum is also small. Phosphorus poisoning does not activate a lipase. None of the methods hitherto employed for determining the fat-hydrolysing power of tissues is quite trustworthy; the quantities of acid formed are too small after short periods of incubation to allow an accurate estimation of their quantity to be made, and the product of autolysis and other circumstances interfere with the correct estimation after longer periods. Any conclusions as to the lipase content of organs under pathological conditions must therefore be accepted with reserve.

**S. B. S.**

**Inosite in Animal Tissues and Fluids.** *Franz Rosenberger* (*Zeitsch. physiol. Chem.*, 1908, 56, 373—377).—A new method of extraction is described which avoids the faults of Scherer’s older method. Fresh flesh contains no inosite (cyclose); it is formed on keeping from a substance named *inositogen*. Ox-blood is free from both substances. Inositogen appears in the human placenta at the sixth month of fetal life; it is present in fresh eggs. The normal urine of men and dogs contains traces of inosite; that of the rabbit does not. The bodies of rabbits after inanition do not form inosite.

**W. D. H.**
Muscular Contraction and Receptive Substances. III. John N. Langley (J. Physiol., 1908, 37, 285—300).—The present experiments deal with the action of nicotine on denervated frog's muscles. Up to 100 days after nerve-section, the local punctiform application of nicotine to the muscles causes tonic contraction, as it does in normal muscles; more dilute solutions cause fibrillary twitchings; for this purpose, however, a somewhat stronger solution is required than in normal muscles. It is therefore certain that nicotine produces its effects on muscle and not on nerve-endings. Possibly the contractile molecule of the muscle fibre has a number of receptive side-chains; combination of one of these with nicotine causes one effect, with another, the other effect. Curare prevents nicotine from causing contraction in muscles, whether denervated or not.

W. D. H.

The Physiology of the Glands. IX. The Relationship between the Hourly Excretion of Nitrogen and Resorption from the Intestine, and its Dependence on Rest, Work, and Diuresis. Ernst Haas (Biochem. Zeitsch., 1908, 12, 203—247).—The hourly output of urine and its nitrogen content were estimated after meals containing known amounts of nitrogen, when the subject of the experiment was doing muscular work, when at rest, and when excessive diuresis was produced by drinking large amounts of tea. The curves representing the output were of a fairly constant form. They showed as a rule three maxima, the first in the second hour, the second in the fifth, and the last in the seventh hour. The first maximum is due to a washing-out of nitrogenous metabolism products owing to the introduction of liquids in the meal; the second and third are due to the resorption of the ingested nitrogenous matter from the intestine. Work or rest have no definite influence on the amount of excreted nitrogen in the first eight hours after a meal. With increased diuresis, there is to a certain extent an increased nitrogenous excretion, which is due, not to increased protein decomposition, but to the washing-out of nitrogenous metabolites already existing in the organism. If the diuresis be brought about before the ingestion of a meal, a smaller quantity of nitrogen is subsequently excreted; this quantity under the conditions of experiments performed was a constant, and amounted to 65% of the nitrogen of the ingested food.

S. B. S.

The Elimination of Non-dialysable Substances by the Urine under Normal and Pathological Conditions. Ulrich Eibecke (Biochem. Zeitsch., 1908, 12, 485—498).—The amount of non-dialysable substance excreted in the urine depends on the amount of substance metabolised. In normal men it varies between 0·870 and 2·356 grams per day—averaging about 1·44 grams. These numbers are markedly higher than those found for females (about 0·8 gram per day). They are also higher than the numbers found in cases of nervous diseases, and of chronic disturbances of the digestive functions. On the other hand, in cases of increased metabolic processes, even with decreased ingestion of food, such as in cases of
fever and diabetes, the reverse is the case. The residue, in normal cases, gave, when tested with the majority of the protein reagents, negative results; on hydrolysis with hydrochloric acid it yielded a reducing substance; probably it consists of chondroitinsulphuric acid and nucleic acid. In the case of pneumonia, however, appreciable quantities of a peptone appeared to be present. In composition, this substance was not far removed from that of the mucin of bronchial mucous membrane, and it yielded on hydrolysis a reducing substance. It is possibly a glucopeptone.

S. B. S.

Colloid Nature of Pigments in Relation to their Behaviour in the Frog's Kidney. Rudolf Höber and S. Chassin (Zeitsch. Chem. Ind. Kolloide, 1908, 3, 76—80).—The experiments described previously (this vol., ii, 716) are extended to twenty-one other dyes. The experiments lead to the following rules: (1) When a dye is not taken up by the kidney epithelial cells it is highly colloidal. The converse is not true, since some colloids are taken up, for example, Biebrich-scarlet, acid-violet, and aniline-blue. (2) When a dye has little or no colloid character, it is readily taken up.

T. E.

A Colour Reaction of Pathological Urine. Otto Gaupp (Biochem. Zeitsch., 1908, 13, 138—141).—Strzyzowski described in diabetic urine a reaction dependent on the amount of acetoacetic acid, the presence of which indicates a bad prognosis; it consists in the appearance of a green fluorescence at room temperature within twenty four to forty-eight hours when formaldehyde is added to the urine. In the present research, it is shown that the prognosis is not necessarily bad, and that the reaction is not specific for diabetic urine, but is found in a large number of other diseases. Ammonia is increased as well as acetoacetic acid in the urine, and a mixture of ammonia, acetoacetic acid, and formaldehyde gives the reaction. The chemical explanation of the reaction is still obscure.

W. D. H.

The Relationship of the Thyroid Gland to the Physiological Action of Adrenaline. Ernst P. Pick and Friedrich Pineles (Biochem. Zeitsch., 1908, 12, 473—484).—The effect of adrenaline injection on the glycosuria and blood-pressure in thyroidectomised animals was investigated. It was found, in the case of rabbits, that the extirpation of the thyroid gland produced no effect on the action of adrenaline as regards its properties of producing glycosuria and diuresis, or of raising the blood-pressure. In the case of young goats, the removal of the thyroid, inhibited adrenaline-glycosuria; the diuretic and blood-pressure-raising properties remained, however, intact.

S. B. S.

The Behaviour of Bromides in the Human and in Animal Organisms. II. H. von Wyss (Arch. exp. Path. Pharm., 1908, 59, 186—195).—The kidneys possess no special capacity for elimination of bromides. After injection of these salts, owing to increased osmotic pressure, the kidneys will become active, but will eliminate, not the foreign salt necessarily, but also the chlorides. There will be,
consequently, a chlorine deficit in the organism, and the toxic effects due to bromides are caused by chlorine starvation; the bromides themselves play a purely passive rôle.

B. S.

Behaviour of Hydroxylamine in the Animal Organism. ROBERTO CIUSA and R. LUZZATTO (Atti R. Accad. Lincei, 1908, [v], 17, i, 834—840).—The authors have made a number of experiments on the toxicity of hydroxylamine and on the presence of the latter or its oxidation products in the urine of animals to which hydroxylamine has been administered, either by ingestion or hypodermically; the blood of the animals was examined spectrosopically.

As a poison, hydroxylamine is four to five times as powerful as nitrous acid. In blood in vitro, hydroxylamine is oxidised, first to nitrous acid and then to nitric oxide, most probably with intermediate formation of dihydroxynammonia, thus: \( \text{NH}_2\text{OH} \rightarrow \text{NH(OH)}_2 \rightarrow \text{N(OH)}_2 \text{ or NH}_2\text{OH} \rightarrow \text{HNO} \rightarrow \text{HNO}_2 \) and \( \text{HNO} + \text{HNO}_2 = 2\text{NO} + \text{H}_2\text{O} \). The blood-spectrum indicates the presence of the nitric oxide compound of hæmoboglin, together with methæmoglobin. T. H. P.

Physiological Action of Optical Antipodes on Higher Organisms. GIUSEPPE BRUNI (Gazzetta, 1908, 38, ii, 1—5).—\( l \)- and \( d \)-Camphors were administered to a number of pairs of rabbits of about equal weight in the proportion of 1.5 gram of 10% camphor oil per 100 grams-weight of the animal, the times of survival of the rabbits after the injection being measured. In the case of \( l \)-camphor, the mean period of survival was 25.4 minutes, and for \( d \)-camphor, 336.7 minutes, so that the toxicity of \( l \)-camphor is thirteen times as great as that of the \( d \)-isomeride. Similar results were obtained by experiments on guinea-pigs. The tastes of the two forms of camphor are markedly different, the \( l \)-isomeride being almost tasteless. T. H. P.

Behaviour of Dextrosephenylosazone in the Organism. LUCIANO PIGORINI (Atti R. Accad. Lincei, 1908, [v], 17, ii, 132—136).—Experiments on frogs, chickens, guinea-pigs, and dogs to which dextrosephenylosazone was administered, either by ingestion or by subcutaneous or peritoneal injection, show that the animals are not affected by the osazone. The conclusion is drawn that the osazone is not resolved in the organism into dextrose and phenylhydrazine, or that, if such resolution does occur, phenylhydrazine is not set free; phenylhydrazine, when administered in the free state, reduces the oxymæhoglobin of the blood to methæmoglobin, besides depressing the nerve centres. T. H. P.

The Pharmacology of Phenanthrene and its Hydroderivatives. HERMANN HILDEBRANDT (Arch. exp. Path. Pharm., 1908, 59, 140—144).—The reduced phenanthrenes are less toxic than phenanthrene itself. The latter is eliminated from the organism in the form of a phenanthrol glycuronate. Dodecahydrophenanthrene, in a rabbit, also gives rise to a glycuronate. In the case of
frogs, phenanthrene itself gives rise to a glycuronate, but not 9:10-dihydrophenanthrene, or derivatives containing more hydrogen.

S. B. S.

The Quantitative Estimation of Synthetical Muscarine by Physiological Methods. Hermann Fühner (Arch. exp. Path. Pharm., 1908, 59, 179—185).—Injection of muscarine solutions into the heart of a toad (Bufo vulgaris) produces in weak solutions diminutions of amplitude of the beat; in stronger solutions, short cessation, with spontaneous recovery, with periodic beats, and with still stronger solutions, total cessation, lasting for some minutes. By perfusing the heart with Ringer's solution, it readily recovers, and can be employed for further experiments. To test the strength of a solution, the heart is first treated with known strengths of a muscarine solution, and the effects produced by each strength noticed. The heart is then perfused with the muscarine solution under investigation, and from the dilution necessary to produce the various effects, the concentration of the muscarine therein can be ascertained.

S. B. S.

The Action of Methyl-green. Hermann Fühner (Arch. exp. Path. Pharm., 1908, 59, 161—178).—Methyl-green is a true quaternary ammonium base, which cannot be extracted from aqueous solutions by ether. It has, accordingly, a curare-like action, and produces paralysis, acting peripherally. This effect is produced in frogs by doses of 2—4 milligrams. 0.03 Gram per kilo is the toxic dose for rabbits when injected subcutaneously. Five times this dose, when administered per os, is without action. It exerts no muscarine-like action on the heart, but acts on the blood-vessels, causing fall of blood-pressure. Pharmacologically, it stands in the same relationship to the methyl-violet, from which it is produced by methylation, as curarine to curarine; methyl-violet, like curarine, exerts no curare-like action, but a digitalis-like action on the heart, which is wanting both in methyl-green and curarine. Methyl-violet is adsorbed by filter-paper and charcoal much more readily than methyl-green, and pigments strongly colour the tissues surrounding its point of application and the organs on which it exerts pharmacological action. Methyl-green, on the other hand, does not pigment very much, and is readily excreted by the kidneys. For this reason, the tinctorial power of methyl-green has failed to throw light on the question of the localisation of its curare-like action.

S. B. S.

The Pharmacology of the Quinatoxins. Hermann Hildebrandt (Arch. exp. Path. Pharm., 1908, 59, 127—139).—The products formed in the isomeric change produced by heating the cinchona alkaloids in acetic acid have been termed the quinatoxins. The experiments indicate that the increased toxicity of these products, as compared with the parent substances, is due to the presence of the piperidine group and the free imino-group. The comparative effects of cinchotoxin, methylcinchotoxin, and other derivatives were investigated.

S. B. S.
Biochemical Investigations of \( p \)-Iodophenylarsinic Acid. Ferdinand Blumenthal and Friedrich Herschmann (Biochem. Zeitsch., 1908, 12, 248—251).—\( p \)-Iodophenylarsinic acid was prepared from atoxyl by slowly diazotising it, and then adding potassium iodide. It is soluble in methyl and ethyl alcohols, but insoluble in other organic solvents, and can be heated to 300° without melting. For physiological investigations, the sodium salt was employed. It is more toxic than atoxyl; 0·1 gram can be injected into rabbits of from 1·5—2 kilograms in weight without marked ill-effects; 0·2 gram is a lethal dose. The animals killed exhibit acute nephritis. The iodine is excreted in the urine apparently in the form of an organic compound, and can be detected therein for some days after the injection.

S. B. S.

Beeswax. Ragnar Berg (Chem. Zeit., 1908, 32, 777—780).—From a study of this wax, the author concludes that yellow beeswax contains aromatic and yellow colouring matters soluble in 80% alcohol and insoluble in light petroleum; chemically-bleached wax contains no such insoluble substances. The odour of the wax appears to be due, in part, to esters of a cholesterol derivative and acetic acid, butyric acid, valeric acid, and an unsaturated liquid acid. The operation of bleaching the wax causes the lower fatty acid esters to decompose. Both bleached and unbleached wax contain at least 0·6% (probably more) of cholesterol esters, which are difficult to saponify, and have high saponification values; only the alcohols give the cholesterol reaction, not the acids. The free wax-acids, which are soluble in 80% alcohol, consist chiefly of unknown acids, together with small quantities of cerotic acid; the bleached wax contains palmitic acid. A supersaturation method is described for showing stearic acid adulteration of beeswax. Dilute acetone, D 0·8450, is used instead of alcohol, enabling so small a quantity as 0·3 gram of stearic acid to be detected in the presence of palmitic and cerotic acids.

J. V. E.

Fatty Acids from Mummies. W. A. Schmidt (Chem. Zeit., 1908, 32, 769—770).—All mummies of whatever age contain fatty acids, and it is of interest to ascertain the alteration in composition of these acids as time progresses. With this object, mummies from about A.D. 500 and about B.C. 1000 have been investigated. From the lungs and muscles of the more recent, 60% and 20—25% respectively of higher fatty acids have been obtained, 40% of which is oleic acid; practically no volatile fatty acids were present. The lungs and spleen of the older mummies contained respectively 12·5% and 30% of higher fatty acids, relatively less oleic acid, and in proportion to the more recent mummies, a considerable quantity of volatile acids.

The liver of a mummy (B.C. 1000) was found to contain 1·6% volatile fatty acids, which are, for the most part, present as the sodium salt.

The author considers that the presence of higher acids is probably due, in part, to the transformation of the mummified albumin, and that the volatile acids may be derived from the slow decomposition of the higher acids, and not directly from the albumin.

J. V. E.
Optical Activity of "Protagon." A New Physical Phenomenon Observed in Connexion with the Optical Activity of So-called "Protagon." Otto Rosenheim and M. Christine Tebb (J. Physiol., 1908, 37, 341—347, 348—354).—"Protagon" dissolved in pyridine possesses at 30° a slight dextrorotatory power, which changes to optical inactivity at higher or lower temperatures, showing finally a maximum laevorotation of −242°, and a final constant laevorotation of \([\alpha]_{D}^{20} = 13.3°\). The prolonged action of boiling or warm alcohol during its preparation or recrystallisation has no influence on these phenomena. Wilson and Cramer's "decomposition" theory of protagon, based on the change of the specific rotation of protagon in pyridine from +6.8° to (+1)13.3° after the action of warm alcohol, is erroneous, and cannot be used for the revival of the view that protagon is a definite chemical compound.

The explanation of the change is as follows: the diamino-phosphatide, sphingomyelin (the constituent of "protagon" rich in phosphorus), is precipitated, when a solution of protagon is kept; it is the appearance of this precipitate which gives rise to the high laevorotation; as the precipitate settles, the laevorotation decreases, and the final laevorotation is due to a small amount of the precipitate which does not settle. But if the precipitate is removed by filtration or centrifugation, the portion of the protagon which remains in the pyridine solution, and is phosphorus-free, is optically inactive. If the precipitate is once more shaken up with this, high laevorotation is again obtained, which lessens as the precipitate once more settles. The high laevorotation is expressed in the usual way, but the optical activity of the precipitated substance does not follow Biot's laws.

On microscopic examination, the precipitate of sphingomyelin is found to consist of anisotropic globules (fluid sphaero-crystals), and their appearance in polarised light is figured. The term sphaero-rotation is proposed for this phenomenon.

The majority of the experiments recorded were performed with protagon or sphingomyelin prepared from brain, but a similar substance with the same remarkable properties was also prepared from the cortex of the suprarenal body.

Chemistry of Vegetable Physiology and Agriculture.

Enzymes [Diastase]. Wilhelm Schneidewind, Diedrich Meyer, and F. Münter (Bied. Zentr., 1908, 37, 503—504; from Arb. Agric.-chem. Versuchstat. Halle, 1906, 2, 67).—Alcohol and ether have a very injurious effect on the action of diastase, and freshly-prepared solutions of diastase are much more vigorous in action than the precipitated substance. It is therefore impossible to obtain information as to the composition of enzymes by studying substances prepared by precipitation.
Albumin, asparagine, and peptone act favourably, so also do weak acids (citric and acetic) at low concentrations (0·001%), but at higher concentrations (0·010%) they retard the action of diastase. Chlorides of the alkalis and small quantities of monophosphates and of aluminium sulphate accelerate the action. One to 2% of monocalcium phosphate or of aluminium phosphate inhibits action altogether.

**Action of Small Quantities of Metals on Lactic Acid Fermentation.** Charles Richet (Bied. Zentr., 1908, 37, 576; from Compt. rend. Soc. Biol., 1905, 60, 455—456).—Minute amounts of barium, platinum, cobalt, manganese, and vanadium were found to cause a slight acceleration in the rate of production of lactic acid.

E. J. R.

**The Catalases of Bacteria.** August Jorns (Arch. Hygiene, 1908, 67, 134—162).—The power of bacteria in bouillon cultures to decompose hydrogen peroxide is due to the presence of a specific catalase, which exists in the form of both an ecto- and endo-ferment. Catalase-formation appears to be a very general property of bacteria, although individual species vary very greatly as regards the intensity of the action.

S. B. S.

**The Chemical Changes Involved in the Assimilation of Free Nitrogen by Azotobacter and Radiobacter.** Julius Stoklasa (Zentr. Bakt. Par., 1908, ii, 21, 484—509)—Both *Azotobacter chroococcum* and *Radiobacter* are widely distributed in nature, especially in soils where the bluish-green algae are numerous; they were not found, however, in the high-lying soils of the Alps. Full details are given of the methods of isolating and studying the organisms.

Experiments on the amount of nitrogen-fixation showed that, contrary to the generally-accepted view, *Radiobacter* has only slight powers of assimilating free nitrogen; thus cultures in 10 and 20 days respectively fixed only 2:2 and 5 milligrams of nitrogen per litre, whilst *Azotobacter* cultures under the same conditions fixed 74:9 and 98 milligrams per litre. Nor is the nitrogen-fixing power of *Azotobacter* greatly increased by symbiosis with *Radiobacter*.

In order that nitrogen-fixation should go on, it is essential that carbohydrate should be supplied, and experiments were made to ascertain the relative values of several sugars. $l$-Arabinose was the most effective, causing 180 milligrams of nitrogen per litre to be fixed; under the same condition, $l$-xylose, dextrose, $d$-galactose, and $l$-evulose enabled 140 to 155 milligrams to be fixed, sucrose 125, maltose 86, but rhamnose only 49.8. The figures for duplicate experiments show somewhat wide variations, but a series of tests with dextrose showed that 99 to 224 grams of this sugar were converted into carbon dioxide and water for every gram of nitrogen fixed. In view of the above results, the author suggests that the furfuroids of the soil furnish the best source of food for *Azotobacter*.

The influence of sodium nitrate on the process was also investigated. This substance inhibits nitrogen-fixation; nevertheless, it is not nearly as useful a food-stuff as free nitrogen. *Radiobacter* is a power-
ful denitrifier, decomposing the nitrate with liberation of free nitrogen.

Respiration is more intense than in any other organism yet studied, 1 gram of the bacterial mass evolving 1.3 grams of carbon dioxide in twenty-four hours. In addition to carbon dioxide, the following substances are also produced from the sugar: ethyl alcohol, hydrogen, formic, acetic, butyric, and lactic acids. E. J. R.

Effect of Pasteurisation on the Development of Ammonia in Milk. W. G. Whitman and Henry C. Sherman (J. Amer. Chem. Soc., 1908, 30, 1288—1295).—Experiments which have been made on the pasteurisation of milk at 65° and 85° have shown that it does not entirely destroy the bacteria which attack the proteins with formation of ammonia, but does destroy, sometimes at 65° and always at 85°, the bacteria or enzymes which cause the decrease of ammonia in raw milk. The estimation of ammonia for the purpose of determining the amount of decomposition of proteins in milk is particularly useful in samples which have been pasteurised at a high temperature, but is of less value in samples which have been pasteurised at low temperatures or not at all, since the amount of ammonia present at any given time cannot be assumed to be proportional to the extent to which protein decomposition has taken place. In the case of samples of New York milk, it was found that, in general, pasteurisation was less efficient in checking the development of ammonia than in retarding the production of acid, and this was especially true of milk pasteurised at the higher temperature (85°), which before becoming sour often showed an amount of ammonia considerably in excess of that produced in raw milk of the same age and origin. It was also found that pasteurisation greatly retarded souring, but favoured the development of an offensive odour and bitter taste, this effect being much less noticeable in samples pasteurised at 65° than in those pasteurised at 85°. E. G.

The Photodynamic Action of Plant Extracts Containing Chlorophyll. Walther Hausmann (Biochem. Zeitsh., 1907, 12, 331—334).—Extracts of various plants containing chlorophyll were shown to exert no hæmolytic action on suspensions of red corpuscles when kept in the dark; if the mixture of corresponding quantities was exposed to light, hæmolysis readily took place.

S. B. S.

Recent Researches on Chlorophyllian Photosynthesis. Eva Mamelí and Gino Pollacci (Att. R. Accad. Lincei, 1908, [v], 17, 1, 739—744).—A destructive criticism of the work of Usher and Priestley (Abstr., 1906, ii, 299, 881; compare also Ewart, this vol., ii, 217). The statement made by Usher and Priestley that green leaves of Elodea, still attached to the plant, do not become reddish-violet when immersed in Schiff's reagent is incorrect. Moreover, when Elodea, killed by immersion in boiling water, is placed in pure water, the same bleaching is seen as was observed by Usher and Priestley in a solution of carbon dioxide; it is probably due to the action of oxygen on the chlorophyll, and not to that of carbon dioxide. The experiments on the production of formaldehyde from carbon
dioxide in an artificial "cell" composed of glycerol and chlorophyll are valueless, because solutions of chlorophyll always give Schiff's reaction. The evolution of oxygen from these artificial cells as described by Usher and Priestley could not be observed. In conclusion, it is pointed out (1) that these workers did not make any direct experiment to prove the presence of hydrogen peroxide in plants; (2) the function of the catalytic enzymes supposed to decompose the hydrogen peroxide is not demonstrated; (3) that all deductions based on the existence of formaldehyde in the plant after the death of the protoplasm and the bleaching of the chlorophyll are erroneous, because formaldehyde is present in the living green cells; (4) that the photolytic decomposition of carbon dioxide in presence of chlorophyll cannot be realised, much less the production of starch under the conditions given by Usher and Priestley. The only facts established are that the phenomena of assimilation are intimately connected with the production of formaldehyde, and that the latter is localised in the chloroplasts, as was already observed by Kimpflin. W. A. D.

The Translocation of Nitrogen Compounds into the Embryo of Barley from the Endosperm and from Artificial Culture Solutions. HORACE T. BROWN (Trans. Guinness Lab., 1, ii, 288. Compare following abstract).—Germinating barley has been shown to contain in the early stages of its life a variety of nitrogenous substances arising from the protein of the original seed; within the first ten days, at least 35% of the seed protein must be transformed. Not all of the nitrogen compounds found after germination are degradation ("down-grade") products; a certain amount represents the surplus nitrogen over and above that required for immediate tissue formation in the growing embryo, and temporarily accumulated for future use ("up-grade" products). It would be possible to discriminate between the two by stopping the vital activity of the embryo in germinating grain without stopping enzyme action, for example, by treatment with chloroform vapour. Useful light is also thrown on the subject by determining the relative nutrient value of the various nitrogenous constituents of the growing grain when these are presented to the detached embryo in water cultures (compare Brown and Morris, Trans., 1890, 57, 483).

The barley was softened somewhat by steeping, and the embryo removed without injury by means of a small knife. A certain number of the embryos were then placed, scutellum downwards, on disks of porous porcelain immersed in Petri dishes containing the nutrient solution in such quantity that the disk was covered without drowning the embryos. The amounts of mineral matter and of sugar supplied were the same in all experiments, but the nitrogen compounds were varied. The compounds used, and the order of their effectiveness, are as follows: tyrosine and phenylalanine (both poisonous at the concentration used); leucine, malt albumoses, and malt peptones (tend to inhibit growth of the plantlets); choline, betaine, allantoin (directly effective as nutrients, and causing assimilation of nitrogen amounting to nearly 50% of that originally present); ammonium sulphate,
aspartic acid, glutamic acid, potassium nitrate, and asparagine show progressive increases in their power to supply nitrogen to the plant.

It is significant that asparagine, the best nutrient found, is much more effective than its hydrolytic products, just as sucrose was found by Brown and Morris to be superior as a nutrient to dextrose and levulose. E. J. R.

The Soluble and Non-coagulable Nitrogen Compounds in Malt. Horace T. Brown (J. Inst. Brewing, 1907, 13, 394—416).—An aqueous extract of malt contains a very complex mixture of nitrogenous substances, even after boiling and removal of the coagulated compounds, and ordinary precipitants were found insufficient to effect complete separations. Thus phosphotungstic acid precipitates about half the nitrogen, but it does not sharply differentiate the complex compounds, and it is possible to isolate both from the precipitate and the filtrate substances having substantially the same properties. Special methods were devised for estimating the nitrogen present as ammonia, and that existing as amides and amino-acids (and therefore liberated by nitrous acid), but these only accounted for 12.5% of the total nitrogen in the extract. An elaborate series of experiments was then made to separate and characterise the remainder of the nitrogen compounds, including salting-out with zinc sulphate and ammonium sulphate, various treatments with alcohol, precipitation with phosphotungstic acid, and the use of dialysis in a special form of dialyser; as far as possible, the experiments were made quantitatively. In this way, some substances were isolated resembling in their main characteristics the albumoses and peptones which result from the digestion of animal proteins under the influence of animal pepsins. The malt albumoses are neutral, soluble in water, not coagulated by heat, and salted-out by ammonium and zinc sulphates. The malt peptones are readily and permanently soluble in water and strong alcohol, are readily diffusible, and precipitable by phosphotungstic acid. In all these respects they agree with the corresponding animal products; they differ, however, in not giving the biuret reaction, and in that the malt peptones are not precipitable by ferric ammonium alum. The division of the "non-coagulable" nitrogen in aqueous and dilute alcohol extracts of malt was found to be as follows:

<table>
<thead>
<tr>
<th>Nitrogen as ammonia</th>
<th>Aqueous extract of malt</th>
<th>Dilute alcohol extract of malt</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.5</td>
<td>2.0</td>

</tr>
</tbody>
</table>

The amino-acids and amides include asparagin, tyrosine, leucine, and allantoin; the organic bases are mainly betaine and choline; the albumoses consist of at least three distinct compounds, and the peptones can be differentiated into at least two.
In examining the several fractions obtained during the investigation of the albumoses and peptones, the author has found the "amino-index" a useful factor. These substances, although neither amides nor amino-acids, liberate a certain amount of their nitrogen on treatment with nitrous acid, and the percentage so liberated is called the amino-index.

Malt albumose I, which represents about one-third of the total albumoses separable by ammonium sulphate, is insoluble in 85% alcohol, and possesses a remarkable power of producing a persistent froth in aqueous solution, a property of considerable interest in connexion with the formation of "head" or foam on malt-worts and beers; its amino-index is 4. Albumose II is soluble in 85% alcohol, and does not possess this frothing power; its amino-index is 5. Albumose III, with amino-index 20, is salted-out with zinc sulphate after removal of Albumoses I and II.

The malt peptones I and II closely resemble each other in general properties, but the amino-index of one is 10·9, and of the other, 19·3.

The author considers that the albumoses and peptones are derived from hordein, the alcohol-soluble protein of barley.

E. J. R.

The Protein Changes Taking Place in Green Plants when Kept in the Dark. Wl. Butkewitsch (Biochem. Zeitsch., 1908, 12, 314—330).—The plants employed in the investigations were beans and cats. The total nitrogen was estimated by Kjeldahl's method, the protein nitrogen by that of Stutzer, the aspartic acid nitrogen by that of Sachsse, and the ammonia nitrogen by that of Bosshard. In the case of beans, the undigestible nitrogen and the nitrogen of the substances precipitable by phosphotungstic acid were also estimated. The analyses were carried out with samples of the original material, and also with samples of material which had remained for different lengths of time in the dark. It was found that there was a decrease of protein nitrogen and an increase in aspartic acid nitrogen. The nitrogen, which was due neither to aspartic acid nor protein, at first increased, and then diminished. The conclusion is drawn that part of the aspartic acid (and another accompanying amide) is formed by a secondary change from products of protein degradation, which include leucine and tyrosine.

S. B. S.

The Function of Calcium in Plants. Viktor Grafe and Leopold Ritter von Portheim (Bied. Zentr., 1908, 37, 571—572; from Naturw. Rundschau, 1907, 22, 255).—The authors find that the injurious effects observed when plants are grown without a proper supply of calcium compounds either fail to appear or are greatly delayed when sugar is supplied. The experiments were made with beans (Phaseolus vulgaris), and the sugars investigated were leevulose, dextrose, and sucrose; of these, leevulose was most effective in delaying the effects of calcium starvation. These results lend support to the view that calcium is concerned in the conversion of starch into sugar in the plant.

Experiments were also designed to ascertain whether calcium acts as a protector against the formaldehyde, which may be supposed to
be produced during the assimilation of carbon dioxide. Plants were grown in normal solutions and in solutions free from calcium; some were kept in the dark and some in the light. Formaldehyde occurred in all plants exposed to light, but it did not occur in plants kept in the dark, even where calcium was withheld. Nevertheless, the characteristic effects of calcium starvation were seen in the latter case, and these experiments do not show any relation between calcium starvation and presence of formaldehyde.

E. J. R.

Occurrence of Calcium Oxalate in the Barks of the Eucalyptus. Henry G. Smith (J. Roy. Soc. New South Wales, 1905, 39, 23—32).—The following amounts of calcium oxalate were found in the bark of different species of *Eucalyptus*: *E. gracilis*, 16.66; *E. Behriana*, 16.50; *E. salubris*, 16.00; *E. oleosa*, 10.64; *E. dumosa*, 9.80; *E. salmonophloia*, 8.34; *E. occidentalis*, 6.82; *E. viridis*, 5.01; *E. redunca*, 4.46; *E. polybractea*, 2.14; *E. stricta*, 0.69, and *E. Morisseti*, 0.08%. The calcium oxalate differs from that usually found in plants in having only one mol. H$_2$O, and in its crystalline form, being similar to the mineral whewellite.

It is suggested that the production of large amounts of oxalic acid may be the cause of stunted growth, and that *Eucalyptus gracilis* is the degenerate form of a larger tree.

The tannin in the barks containing much calcium oxalate is decidedly superior to the tannin of barks in which only small amounts are present.

N. H. J. M.

Aluminium, the Chief Inorganic Element in a Proteaceous Tree, and the Occurrence of Aluminium Succinate in Trees of this Species. Henry G. Smith (J. Roy. Soc. New South Wales, 1904, 37, 107—120).—Four specimens of *Orites excelsa*, one of the trees known in Australia as "Silky Oak," were found to contain large amounts of aluminium. When excessive amounts of aluminium are taken up by the trees, deposits of basic aluminium succinate are formed. The deposits contain also free butyric acid.

Samples of the wood from (1) Queensland, (2) Mullimbimby, (3) Dorrigo, and (4) Bangalow, contained 0.639, 0.684, 0.673, and 0.706% ash, the composition of which was as follows:

<table>

The ash of (2) contained traces of cobalt. Iron was present only in traces.

The sap of *Grevillea robusta* was found to contain butyric acid. No aluminium could be detected in the ash of five varieties of *Grevillea*.

N. H. J. M.

Ochoco Fat. Julius Lewkowitsch (Analyst, 1908, 33, 313—315).—A fat, consisting of about 98% of myristin and 2% of olein, is yielded by the seeds of *Scyphocephalium ochoco*, a tree
found on the West Coast of Africa. The kernels of the seeds yield about 58·8% of the fat, but by whatever process the fat is prepared, a dark brown colouring matter is at the same time extracted; this colouring matter is contained, not only in the husks, but also in the spermoderm which passes through the whole of the endosperm in the form of irregular lamellae. The white endosperm, cut out carefully by hand, yielded a fat having the following chemical and physical constants: $D_4^0 = 0.8899$; saponification number, 238·5; iodine number, 1·72; Reichert-Meissl number, 0·65; m. p. 45—48°; unsaponifiable matter, 0·37%; mean molecular weight of the fatty acids, freed from unsaponifiable matter, 221·9; m. p. of fatty acids, 47·2°; the extracted fat had the acid number 1·42. The seeds are obtainable in large quantity.

W. P. S.

Carrotene from Carrots. LEON MARCHEWSKI (Zeitsch. physiol. Chem., 1908, 56, 554. Compare Euler and Nordenson, this vol., ii, 724).—The author has shown previously that carotene when oxidised does not yield a derivative of cholesterol.

J. J. S.

Absence of Gum and Presence of a New Diglucoside in the Kinos of the Eucalyptus. HENRY G. SMITH (J. Roy. Soc. New South Wales, 1905, 38, 21—36).—Freshly-exuded kinos of Eucalyptus paniculata yielded a diglucoside, emphloin, which is insoluble in alcohol. When hydrolysed, it yields 44·47% of a sugar, from which an osazone, m. p. 176—178°, was obtained. The sugar, which is probably isomeric with melibiose, is without optical activity, presumably owing to internal compensation.

When the glucoside is boiled with dilute acid, a precipitate of "kinored" is produced. This yields protocatechuic acid when heated with potassium hydroxide.

The astringency values of about 100 species of Eucalyptus were determined. Compared with gallo-tannic acid, containing 14·43% of water, = 1000, the values for $E. pilularis$, $E. macrorrhyncha$, and $E. eugenioides$ (containing about 18% of water) were 838, 835, and 811 respectively. The kinos of $E. paniculata$ and other "iron-barks" have only about half their values, owing to their glucosidal nature, and it will be necessary to hydrolyse the glucoside while in the pits (perhaps by means of an enzyme) to render them suitable as tanning materials.

N. H. J. M.

Barks of Rhamnus Frangula and Rhamnus Purshiana. ALEXANDER TSCHIRCH and J. F. A. POOL (Arch. Pharm., 1908, 246, 315—325).—The emodins isolated from the two barks are identical; a substance, m. p. 165°, which was, in addition, obtained from Frangula bark, is probably chrysophanic acid; neither bark contains rhein. Tschirch and Edner’s assay-method for rhubarb (Abstr., 1907, ii, 515) is not applicable to the barks in question, but Warin’s colorimetric method (Abstr., 1905, ii, 659) appears to be of more importance. The addition of magnesia to the powdered drug before percolation, in order to remove the bitter taste from the extract, does not greatly affect the total hydroxymethylantrachonine-content of the
Origin of the Colour of Red Grapes. Philippe Malvezin (Compt. rend., 1908, 147, 384—386.* Compare Laborde, this vol., ii, 774).—When unripe, green berries of red grapes are heated with distilled water for seventeen hours at 85°, an intense yellow colour is developed, which at the end of twenty-four hours changes to red. The red coloration is due to oxidation by the air, since in absence of air only the yellow colour is obtained. A similar series of colour changes occurs when green berries of white grapes are treated in the same way. The leaves and stalks of the vine, however, give only the yellow colour.

The author ascribes the red colour of grapes to the existence of a single chromogenic compound, which in his experiments is transformed into the red substance under the influence of air, heat, and probably light, the same transformation being brought about in nature by a specific enzyme. The absence of colour in white grapes is considered to be due to the absence of this enzyme. The chromogenic substance is unstable, and is precipitated when the heating at 85° is prolonged; on raising the temperature, however, the original brilliant red colour reappears, and this process can be repeated a certain number of times.

W. O. W.

The Action of Sulphur Dioxide on Plants. A. Wieler (Bied. Zentr., 1908, 37, 572—573; from Naturw. Rundschau, 1907, 22, 229).—Assimilation of carbon dioxide is profoundly influenced by the presence of sulphur dioxide, but respiration is not affected. Examination of the leaves of plants from districts where sulphur dioxide causes injury showed that this substance is present in the leaf, although only in small quantities, except in cases where the leaves are close to the source of origin of the gas, when larger amounts are found. The sulphur dioxide enters through the stomata, and causes greater injury in wet than in dry weather, because the stomata are more widely open.

There is evidence that some other factors come into play besides the direct action of sulphur dioxide in the leaf; for instance, the soils in the districts where injury arises are acid. It is concluded that injury can usually be overcome by suitable manuring, and, in particular, by liming.

E. J. R.

The Quantity of Arsenic contained in Wines obtained from Vines which have been Treated with Arsenical Washes. Pierre Breteau (J. Pharm. Chim., 1908, [vi], 28, 154—158).—Ten samples of wine obtained from vines which had been treated with arsenical washes or sprays were found to contain quantities of arsenic varying from 0·003 to 0·20 milligram per litre; one sample was free from arsenic. Four other samples, also coming from vines similarly treated, but which had received the addition of quantities of sulphuric acid, bisulphite, &c., contained from 0·03 to 0·10 milligram of sulphuric per litre.

W. D. H.

Composition of the Air in Soils. Erich Lau (Bied. Zentr., 1908, 37, 433—434).—The author discusses the variations in the amount of carbon dioxide present in the air of the soil. The soil air is richest in carbon dioxide in summer and poorest in winter, the maximum being reached in July, and the minimum in February. Only small amounts are found in sandy soils, more in clays and loams, and a still larger quantity in peaty soils, corresponding with the increasing amounts of humus present; the physical properties of the soil also influence the quantity. Less is found at the surface than lower down; the difference is more marked in the case of peaty than of sandy soils. The amount of oxygen in the soil air depends on the amount of carbon dioxide, hence it is clear that the latter is formed by oxidation of humus.

Some of the carbon dioxide is also produced by the plants growing in the soil, and the amount present in soils carrying crops is always greater than in fallow soils; the amount also increases with the temperature and the weight of the crop. Potatoes and lupins especially cause an increase in the carbon dioxide, indicating that their respiratory processes are more intense than those of other plants.

Dung also increases the amount of carbon dioxide present.

E. J. R.

Some Properties of the Organic Matter in the Soil. The Osmotic Pressure of the Soil Moisture. Josef Konic, Julius Hasenräumer, and H. Grossmann (Landw. Versuchs.-stat., 1908, 69, 1—92).—The authors have examined a method suggested by Coppenrath (Landw. Versuchs.-stat., 1907, 66, 401) for determining the amount of available plant food in soils, namely, heating the soil (500 grams) with water (5 litres) for five hours under 5 atm. pressure. The plant food goes into solution either as complex salts or as organic substances. Great differences in composition, such as would be found in soils of widely different types, are thus brought out, but not the slight differences produced by adding to a given soil artificial manures in quantities commensurate with those used in practice. Hydrogen peroxide also dissolves plant food from the soil, and in somewhat higher quantities than the above method, but it also fails to discriminate between manured and unmanured soils of the same type when the amount of added manure is only small.

The analytical value of the method was established by pot experiments, which showed that the amount of potash taken by the plant, and therefore "available" for the plant, was much the same as that dissolved by the above processes. Since the amount of plant food dissolved by these methods is higher than that extracted by pure water, or water saturated with carbon dioxide, it follows that some of the soil humus must furnish mineral matter to the plant. For the same
reason, potash appears to be set free from some of its insoluble compounds during the growth of the plant.

An apparatus is described by means of which a measure of the osmotic pressure of the soil solution can be obtained. It is suggested that such measurements might throw much light on the solubility of soil constituents.

E. J. R.

Isolation of Picolinecarboxylic Acid from Soils and its Relation to Soil Fertility. Oswald Schreiner and Edmund C. Shorey (J. Amer. Chem. Soc., 1908, 30, 1295—1307).—A sample of soil from Takoma Park, Md., was found to contain 3% of organic matter, 0.1% of nitrogen, and sufficient mineral substances for ordinary crops. Nevertheless, this soil was very unfertile, and did not respond readily to treatment with manures. It was found that this was due to the presence of toxic substances, and a careful investigation was therefore carried out, with the result that picolinecarboxylic acid was isolated.

2-Picoline-4-carboxylic acid was obtained by Böttinger (Abstr., 1881, 612; 1884, 758) by the action of heat on uvitonic acid, the latter being easily prepared by treating pyruvic acid with alcoholic ammonia. Indications were obtained of the presence of pyruvic acid in the soil, but no evidence could be obtained of the presence of uvitonic acid.

A series of experiments has been carried out with a view to ascertaining the toxicity of various organic substances on wheat seedlings (compare Schreiner and Reed, this vol., ii, 420). It has been found that picolinecarboxylic acid in very low concentrations acts as a stimulant, but is decidedly injurious when present to the extent of 100—200 parts per million. The amount of picolinecarboxylic acid in the Takoma Park soil was not sufficient to account for the full toxic effect, but this was chiefly due to the presence of dihydroxystearic acid. Uvitonic acid is much more toxic than picolinecarboxylic acid. Pyruvic acid exerts a toxic action, but its sodium salt is inactive. Pyridine and picoline are very injurious, and piperidine is even more so.

E. G.

Effect of Lime on the Availability of the Soil Constituents. Frederick B. Guthrie and L. Cohen (J. Roy. Soc. New South Wales, 1907, 41, 61—66).—About 10 lb. of a light sandy soil, a garden loam fairly rich in humus, and a very stiff clay were mixed with 1% freshly-slacked lime and, along with duplicate portions without lime, exposed to the sun and rain for a month, being kept moist the whole time.

The clay to which lime was added became friable in a fortnight. In the soils which had no lime, the water-soluble phosphoric acid decreased considerably, and in the case of the clay soil the water-soluble potassium decreased as well. Application of lime lessened the decrease in water-soluble constituents, and in the sandy soil increased the proportions both of phosphoric acid and potassium soluble in water above those originally present.

The amounts of constituents soluble in citric acid changed very slightly, and the effect of liming was less marked.
As regards the soluble nitrogen, application of lime was found to increase the amount of nitrates, whilst the amount of nitrites remained almost the same, except in the case of the clay soil, which showed a loss of nitrate under the influence of lime. The largest amount of soluble nitrogen in the unlimed soil was in the form of ammonia, of which the limed soil contained very little.

N. H. J. M.

Chemical Examination and Calorimetric Test of Indiana Peats. R. E. Lyons and C. C. Carpenter (J. Amer. Chem. Soc., 1908, 30, 1307—1311).—Twenty-nine samples of peat from the lake region of Northern Indiana have been tested for calorific value, and five typical specimens of Indiana peats have been submitted to complete analysis. The maximum heating effect was given by a specimen of sphagnum moss peat from a bed 20 feet thick, exhibiting almost complete decomposition and a dark chocolate colour, whilst the minimum effect was given by an impure, highly oxidised peat derived from grass and sedge. In general, the results showed that the best Indiana peat has a calorific value equal to the best grade of peat found in other parts of the United States and in Europe.

E. G.

Manurial Trials with Calcium Cyanamide and (Swedish) Calcium Nitrate. Hjalmar von Feilitzen (Bied. Zentr., 1908, 37, 498—499; from Landwirtsch. Presse, 1907, 229 and 243; see also Abstr., 1906, ii, 487).—The experiments show that calcium cyanamide acts almost as favourably as ammonium salts, although not as well as sodium nitrate, on oats, barley, wheat, and potatoes growing on sandy or clay soils. It also acts well on the better moor soils (Misch-u. Niederungsmooren), but on the poorer soils (sphagnum and high moorland) it was not as good.

Calcium nitrate gave much better results, and was fully as good as sodium nitrate even on the high moorland soils; indeed, on oats it was better than sodium nitrate.

E. J. R.

Pot Experiments to Determine the Limits of Endurance of Different Farm Crops for Certain Injurious Substances. Frederick B. Guthrie and R. Helms (J. Roy. Soc. New South Wales, 1904, 37, 165—171. Compare Abstr., 1905, ii, 755).—The following numbers indicate the percentages of the different substances employed, and their effect on maize grown in a fairly rich garden loam.

### Analytical Chemistry.

The Importance of Hygroscopy in General Analysis. C. Reichard (Pharm. Zentr-h., 1908, 49, 759—763).—Attention is directed to the deductions which may be drawn as to the nature of a salt from an observation of its hygroscopic properties. Instances are given of salts which are similar in appearance, but may be distinguished from one another by one having the power of absorbing water from the atmosphere. Thus, a crystal of sodium iodide, exposed side by side with a crystal of potassium iodide, will absorb enough water to give a complete solution, whilst the potassium salt remains practically dry. Barium chloride is readily distinguished from the hygroscopic calcium and strontium chlorides. Sodium metaphosphate is hygroscopic, and differs from sodium orthophosphate in this respect. Other salts exhibiting this difference are potassium acetate and sodium acetate, copper sulphate and copper nitrate, &c.

W. P. S.

Qualitative Centrifugal Analysis. B. C. P. Jansen (Chem. Weekblad, 1908, 5, 501—593).—The author finds that the use of the centrifuge in qualitative analysis affords a method which is superior to the ordinary filtration process in speed, ease of manipulation, and cleanliness. Its use is not more expensive than that of good filter-paper.

A. J. W.

A. J. W.

Compound Gas-Pipette. Hans Fleissner (Chem. Zeit., 1908, 32, 770).—The troublesome operation of filling the compound Hempel pipette is avoided by having a small vertical tube sealed to the communication tube of the central top bulb. When the pipette is filled with the aid of a funnel and a piece of rubber tubing, the tube is closed with a rubber tube carrying a glass rod.

L. de K.
Physico-chemical Analysis of Wines. Paul Dutoit and Marcel Duboux (Compt. rend., 1908, 147, 351—353. Compare this vol., ii, 781).—Berthelot's method for determining the end point in acidimetry by means of the electrical conductivity of the solution, furnishes higher results when applied to the analysis of the distillation products of wines than the usual process. The total quantity of basic substances exceeds the amount of ammonia determined gravimetrically or colorimetrically; the difference represents the volatile organic bases, the quantity of which varies considerably with the nature and age of the wine. The method has also been employed to estimate the volatile acids, but the results are found to depend to a certain extent on the method of carrying out the distillation.

Estimations of the organic bases and colloidal tannins have shown a deficiency of one or both of these constituents in inferior wines ("piquettes") and wines prepared from raisins. W. O. W.

Qualitative and Quantitative Separation of Metals. M. Emmanuel Pozzi-Escot (Bull. Soc. chim. Belg., 1908, 22, 327—338).—A new course shown in six tables and including the rarer metals. The process much resembles the ordinary course, but deviates from this in the treatment of the filtrate resulting from the action of hydrogen sulphide. This, after expelling the hydrogen sulphide by boiling, is mixed with an excess of sodium hydrogen phosphate, sodium hydroxide, and sodium hypobromite, and again boiled.

L. de K.

Detection and Estimation of Free Mineral Acids in Red Wines. Charles Astre (Bull. Soc. chim., 1908, [iv], 3, 928).—The process depends on the partial separation of the mineral acid from the other constituents of the wine by dialysis. For quantitative purposes, parallel experiments are made with the suspected wine and with one of similar type, the dialysed products being titrated with N/10 alkali. Details as to the quantities to be used, &c., are given in the original.

T. A. H.

Simple Method for the Estimation of the Halogen in Mercuric Chloride and Mercuric Bromide. Moritz Kohn (Zeitsch. anorg. Chem., 1908, 59, 271—272).—Mercuric chloride and bromide are decomposed by alkaline solutions of hydrogen peroxide more readily than the iodide (compare this vol., ii, 696). Metallic mercury separates, and is filtered off after the solution has been heated to near its boiling point to remove the excess of hydrogen peroxide. The halogen in the solution is then estimated by means of silver nitrate.

H. M. D.

Estimation of Sulphur in Mineral Sulphides. V. Hassreidter (Bull. Soc. chim. Belg., 1908, 22, 308—316).—A review of the recent methods proposed, particularly that recommended by Lunge. The author is of opinion that the problem of exact estimation of sulphur is not as yet quite solved, especially in the case of zinc ores.

L. de K.

Estimation of Sulphurous Acid in Gelatins and other Foods. L. Padé (Ann. Chim. anal., 1908, 13, 299—301).—Twenty grams of dry gelatin, or 100 grams of jelly, are placed in a flask containing 500 c.c. of boiled water. The flask is fitted with a cork through which pass the usual inlet and outlet tubes and also a separating funnel containing 25 c.c. of syrupy phosphoric acid. After twelve hours, a current of carbon dioxide is passed; the liquid is heated at 70°, and the free sulphur dioxide absorbed in nitrogen bulbs containing iodine solution. After an hour, the bulb-tube is changed, the phosphoric acid is introduced from the funnel, and the operation continued for another hour. In this way, the sulphur dioxide present as sulphites is expelled.

The sulphur dioxide is converted by the iodine into sulphuric acid, which is then estimated gravimetrically.

L. de K.

Ammonia Distillation in the Presence of Magnesium or Calcium Salts. Philip Adolph Kober (J. Amer. Chem. Soc., 1908, 30, 1279—1281).—The time required for distilling off the ammonia in Folin's method of estimating carbamide (Abstr., 1903, ii, 116) is three or four times greater than that required for ordinary ammonia distillations. Further, the results of such ammonia distillations show considerable variation, especially when made in the presence of magnesium or calcium salts. These facts are discussed, and an explanation is given.

The solvent action of ammonia or its salts on magnesium hydroxide is due to the following reaction: MgCl₂ + 2NH₄OH = Mg(OH)₂ + 2NH₄Cl. The liquid from which the ammonia is distilled in Folin's estimation contains a large excess of magnesium chloride, and some ammonium chloride, magnesium hydroxide, and ammonia. As the concentration of the magnesium hydroxide is extremely small and that of the magnesium chloride relatively great, equilibrium will not occur until most of the ammonia is in the form of ammonium chloride. A small amount of the ammonia is removed by distillation, and the equilibrium is disturbed, so that a further quantity of ammonium hydroxide is formed. This gradual change explains the slowness with which the ammonia passes over in carbamide estimations made with magnesium or calcium chloride. It has been found very difficult, if not impossible, to distil ammonia from an alkaline saturated solution of magnesium or calcium chloride. It is therefore evident that quantitative ammonia distillations should not be carried out in the presence of large quantities of magnesium or calcium salts.

E. G.

Electrolytic Estimation of Nitric Acid. Owen L. Shinn (J. Amer. Chem. Soc., 1908, 30, 1378—1381).—Easton (Abstr., 1904, ii, 84) has studied the reduction of potassium nitrate to ammonia by
electrolysis in presence of copper sulphate. A further investigation was made by Ingham (Abstr., 1905, ii, 61), who, by employing a high current density and a rotating anode, obtained very accurate results. As several subsequent workers have been unable to obtain satisfactory results by this method, a series of experiments has been made in order to determine the best conditions. It has been found that Ingham’s results can be obtained if the anode is rotated slowly so as to prolong the precipitation of the copper. The current should be about 4–5 amperes and 10 volts, and not more than about 20–25 c.c. of N/5 sulphuric acid should be present. It is sometimes necessary to add a second or even a third quantity of copper sulphate in order to complete the reduction.

One hundred c.c. of the wine are concentrated in a flask to 15 c.c., and, when cold, 6 c.c. of a saturated solution of ferrous sulphate and 4 c.c. sulphuric acid are added and the liquid slowly boiled. By means of a condenser, the vapour is collected in a suitable vessel containing 2 or 3 c.c. of a specially prepared, acidified starch-potassium iodide solution. When nitrates are present in the wine, a blue ring is produced in the starch solution, either at once or in the second or third small fraction, according to the quantity present.

The starch solution is prepared by shaking starch with water, then warming on a water-bath, and adding zinc chloride; after again heating and allowing to cool, the potassium iodide is added. This method of detecting nitrates is not applicable to must, or wine of a high extract content; with such, the following method of Zecchini is advised. The must is evaporated to dryness with fresh lime on a water-bath, and then extracted with 96% alcohol and filtered; the filtrate is evaporated, extracted with water, and then submitted to the test described above for wine.

Detection of Phosphoric Acid in Stones, Ores, and other Minerals. Alexander P. Lidoff (J. Russ. Phys. Chem. Soc., 1908, 40, 817–822).—The presence of phosphoric acid in minerals may be readily detected as follows: The finely-powdered mineral is first strongly heated in a crucible or iron tube in order to free it from water, organic matter, and carbon dioxide. From 0.080 to 0.100 gram of the cooled mineral is then mixed with approximately 0.3–0.35 gram either of magnesium or of a mixture of about 65% of magnesium and 35% of aluminium. The mass is introduced into an iron tube about 5–6 cm. long and 5 mm. in diameter, a loose plug of asbestos being placed above it. The tube is then heated until the lower end becomes dull red, after which it is rapidly cooled and the contents mixed with a thick wire and introduced into a test-tube with a spherical enlargement at the upper part. In this tube, the substance is gently heated with 20% potassium hydroxide solution, the gases evolved being passed through a calcium chloride tube and a plug of cotton wool, and over a strip of filter paper moistened with copper acetate slightly acidified with acetic acid. If phosphorus is present,
the filter paper blackens, owing to the formation of copper phosphide, and in moist air, gradually becomes decolorised, in consequence of the oxidation to colourless copper phosphite.

A dark coloration of the filter paper moistened with copper acetate is also determined by arsenic or nitrogen in the mineral. In the former case, the hydrogen arsenide sometimes gives a characteristic metallic arsenic deposit, which is not easily confused with the blackening due to the formation of copper phosphide, and which remains unchanged in the air. When nitrogen is present in small proportion, the small amount of ammonia evolved simply forms ammonium acetate, and the colour of the filter paper remains unchanged; when much ammonia is evolved, a dark blue solution of copper oxide in ammonia is formed on the filter paper, which changes to the cinnamon colour of cuprous oxide on heating. Experiment shows that magnesium does not absorb an appreciable proportion of nitrogen at a red heat.

T. H. P.

Titration of Phosphoric Acid in Superphosphates. S. Kohn (Chem. Zeit., 1908, 32, 718—719).—A slight modification of the author’s process (this vol., ii, 531). Fifty c.c. of the aqueous solution of the sample are diluted with 300 c.c. of water, and titrated with standard sodium hydroxide, using a mixture of methyl-orange and indigotin as indicator. Another 50 c.c. are then mixed with an excess of calcium chloride, and titrated without further dilution, using phenolphthalein as indicator. Salts of iron or aluminium do not interfere.

L. De K.

Estimation of Phosphoric Acid as Phosphomolybdic Acid. P. Christensen (Zeitsch. anal. Chem., 1908, 47, 529—545. Compare Abstr., 1907, ii, 652).—The estimation of phosphoric acid by direct ignition of the precipitate of ammonium phosphomolybdate was found to be trustworthy for the analysis of soils if carried out in the following manner. A known volume of the extract of the soil (equivalent to about 33 grams of the latter) is evaporated to dryness after the addition of a few drops of nitric acid; the residue is then moistened with a little nitric acid, again evaporated, and heated to a temperature of about 120° for fifteen minutes. The residue is next treated with about 25 c.c. of boiling water and a few drops of nitric acid, the silica is collected on a filter, and washed with water until the filtrate measures about 40 c.c. The filtrate is neutralised by the addition of ammonia, D 0·91, a further 8 c.c. of ammonia are added, and then 10 c.c. of concentrated nitric acid. The mixture is heated to about 50°, and, when all the precipitated ferric hydroxide has re-dissolved, molybdic acid solution is run in with constant stirring. About 10 c.c. of the latter solution are added for every 0·1 gram of phosphoric oxide present. After the lapse of three hours, the precipitate is collected on a filter, washed with a 5% ammonium nitrate solution containing 1% of nitric acid, dried, and ignited at a temperature not exceeding a dull red heat; the filter paper is burnt before adding the precipitate to the crucible, and the latter is not covered until the ignition is nearly
completed. The weight of the precipitate multiplied by 0.0394 gives the quantity of phosphoric oxide.

W. P. S.

Direct Estimation of Phosphoric Acid as Ammonium Phosphomolybdate. Emil Raben (Zeitsch. anal. Chem., 1908, 47, 546).—As ammonium nitrate is readily soluble in alcohol, the yellow precipitate of ammonium phosphomolybdate obtained in the usual way in the estimation of phosphoric acid may be washed with alcohol, and weighed. The precipitate is collected on an asbestos filter, washed with ammonium nitrate solution, then a few times with warm 70% alcohol, once with absolute alcohol, and, finally, with a little ether. The precipitate is dried to constant weight at a temperature of 110—120°.

W. P. S.

Pemberton’s Method for the Estimation of Phosphoric Acid. G. H. G. Lagers (Zeitsch. anal. Chem., 1908, 47, 561—571. Compare Abstr., 1907, ii, 907).—The method was found to give trustworthy results if the solution containing the water-soluble phosphoric acid received the addition of at least 58 milligrams of sulphuric acid before the phosphoric acid was precipitated with the molybdate reagent. When smaller quantities of sulphuric acid (compare Abstr., 1905, ii, 419) were added, the results obtained were too low.

W. P. S.

Detection of Traces of Arsenic in Various Substances, and the Sensibility of the Usual Methods. C. H. Nieuwland (Chem. Weekblad, 1908, 5, 558—561).—Sjollema’s method (this vol., ii, 224) can be applied to the detection of traces of arsenic in milk, urine, wheat-meal, beef-suet, calico, beer, wall-paper, bones, bone-marrow, and yams. The arsenic was introduced by means of a solution of potassium arsenite containing 0.1 milligram of arsenious oxide per c.c. Gutzeit’s test is more delicate; but with not less than 0.05 milligram of arsenious oxide, Sjollema’s method enables arsenic to be distinguished from antimony and phosphorus.

A. J. W.

Detection of Boric Acid in Foods by means of Turmeric Paper. Francisco P. Lavalle (Chem. Zeit., 1908, 32, 816—817).—In order to render turmeric paper more delicate, it has been recommended to extract the turmeric powder with benzene before preparing the tincture. The author states that a reaction for boric acid obtained by means of this paper must on no account be taken as proving a wilful addition of boric acid; the reaction is too delicate, showing the (apparent) presence of boric acid even in such reagents as pure hydrochloric acid, sodium chloride, &c.

L. de K.

The Estimation of Graphite. Frank Browne (Chem. News, 1908, 98, 51).—The author has studied the influence of heat on the conversion of ferric oxide into the magnetic oxide, and, as a result, has devised the following process for the estimation of graphite: Some ferric oxide is heated to redness in a covered crucible for two to three hours; the resulting oxide is a nearly black, slightly coherent magnetic powder. About 5 grams of this oxide are heated in an uncovered
wide mouthed crucible at a pale red heat for an hour, with occasional stirring; after weighing, 0·5 gram of graphite is added and heated as before for one or two hours, with occasional stirring, again weighing. The carbon is burnt off, and the oxide remains unchanged. The results agree fairly closely with those obtained by the potash fusion method. The mineral matter of coal may be estimated in the same way, but the amount found will be about 0·5 per cent. higher than when estimated in the ordinary manner, owing, probably, to interaction of the constituents of the ash.

P. H.

Estimation of Potassium in Silicates. Wilhelm Autenrieth (Centr. Min., 1908, 513—517).—The mineral is decomposed by heating with hydrofluoric and sulphuric acids. When dry, the mass is extracted with boiling water, and the solution freed from iron, etc., by boiling with excess of sodium acetate. After concentrating to about 20 c.c., the potassium is precipitated as cobalt-yellow by addition of 5—10 c.c. of de Koninck's cobalt reagent. As, however, the precipitate is not of constant composition, it is dissolved in hydrochloric acid, and the residue left on evaporation is treated for potassium by the well-known perchlorate method. The potassium may be estimated also by the usual platinic chloride method; in this case, the cobalt must be eliminated by gently igniting the precipitate and extracting the mass with hot water.

The cobalt reagent is prepared by dissolving 30 grams of crystallised cobalt nitrate in 60 c.c. of water, adding 10 c.c. of a saturated solution of sodium nitrite, and then 10 c.c. of glacial acetic acid. After a few days, the reagent is poured off from any deposit, and is then fit for use; it keeps, in the dark, for about a month.

L. de K.

Estimation of the Alkaline Earths [in Waters] by means of Potassium Stearate and Phenolphthalein. C. Blacher and J. Jacoby (Chem. Zeit., 1908, 32, 744—745).—The carbonates are first titrated with $\frac{N}{10}$ hydrochloric acid, using methyl-orange as indicator, and the carbon dioxide is removed by a current of air. Phenolphthalein and a few drops of alcoholic $N$-alkali are added, and the liquid is decolorised with $\frac{N}{10}$ hydrochloric acid. After adding an extra 0·02 c.c. of acid, the total hardness is determined by titrating with $\frac{N}{10}$ potassium stearate until the liquid turns red. The calcium is estimated in the presence of magnesium by placing 200 c.c. of the water in a flask and weighing the same. After neutralising with $\frac{N}{10}$ hydrochloric acid, the carbon dioxide is boiled off, 1—3 c.c. of $N$-alcoholic alkali is added, and the loss in weight restored by adding water free from carbon dioxide. The liquid is filtered while still hot, and, when cold, 100 c.c. are neutralised as directed, and the calcium is titrated with the stearate solution. Sulphates may be titrated indirectly by precipitating with a slight excess of barium chloride and determining the excess with the stearate solution, allowance being made for any calcium and magnesium present.

The reagent is prepared by dissolving 28·4 grams of stearic acid in 400 c.c. of hot alcohol and 250 grams of glycerol, and neutralising.
with alcoholic potassium hydroxide. When cold, the whole is diluted with alcohol to one litre. If desired, the solution may be checked with lime-water and \( \frac{N}{10} \) acid.

L. de K.

Volhard's Copper Titration. H. Theodor (Chem. Zeit., 1908, 32, 889—890).—Volhard's process (precipitation of copper in presence of sulphurous acid with ammonium thiocyanate and estimation of the excess of the latter with silver solution) is strongly recommended.

L. de K.

Analysis of Bronzes, Brass, and Similar Alloys. E. Schürmann and H. Arnold (Chem. Zeit., 1908, 32, 886—887).—The solution of the alloy, which should contain, besides tartaric acid, about 5% of free nitric acid, is submitted to electrolysis; conditions, \( 1\frac{1}{2} \) amperes and 4 volts. This precipitates the copper only (which, however, should be examined for traces of tin), whilst antimony and tin remain in solution. After rendering alkaline with potassium hydroxide, lead and any copper still present are precipitated by cautious addition of potassium sulphide, and then treated by the usual methods. The filtrate is boiled with addition of 0.5 c.c. of hydrogen peroxide, and, after neutralising with oxalic acid, an aqueous solution of 5 grams of that acid is added. The liquid is diluted to 400 c.c., heated to boiling, and treated with hydrogen sulphide to precipitate the antimony, which is then collected, dissolved in sodium sulphide, and submitted to electrolysis. The filtrate from the antimony is neutralised with ammonia, acidified with acetic acid, heated to boiling, and treated with hydrogen sulphide. The tin sulphide is then converted as usual into tin oxide.

A number of test-analyses are given.

The process is also applicable to the analysis of brass. After the copper has been separated electrolytically, the liquid is treated with hydrogen sulphide, and the precipitate submitted to the usual process. The filtrate containing the zinc is then analysed for zinc in the ordinary way.

L. de K.

Estimation of Manganese in Iron and Manganese Ores. Max Orthen (Zeitsch. anal. Chem., 1908, 47, 547—560).—The results of a critical examination of some of the methods now in use for the estimation of manganese are given, particular attention being paid to the more rapid volumetric processes. For the estimation of manganese in iron and manganese ores, the methods proposed by Volhard-Wolff, von Knorre (Abstr., 1902, ii, 108), and Blair (Abstr., 1904, ii, 633) were found to be trustworthy, the results obtained agreeing well with those yielded by the ordinary gravimetric method.

W. P. S.

Direct Combustion of Steel for Carbon and Sulphur. Helen Isham and Joseph Aumer (J. Amer. Chem. Soc., 1908, 30, 1236—1239).—Experiments showing that the carbon in steel is almost completely eliminated by direct ignition in a current of
oxygen, whereas the sulphur cannot be expelled completely in this manner.

The results for carbon average 0·004% more than those obtained by the usual copper chloride method.

L. de K.

Loss of Carbon during Solution of Steel in Potassium Cupric Chloride. Ernest P. Moore and Jas. Watson-Bain (J. Soc. Chem. Ind., 1908, 27, 845—846).—In order to ascertain whether there is actual loss of carbon when steel is dissolved in potassium cupric chloride solution, the authors carried out experiments in which the samples of steel were dissolved in the solution in a flask through which a current of air free from carbon dioxide was passed. After leaving the flask, the air was passed over heated cupric oxide, and then through barium hydroxide solution. The barium carbonate formed was collected and estimated. From the results obtained, it is seen that the loss of carbon from 1 gram of steel amounted to from 0·0004 to 0·0005 gram. The two samples of steel used in the experiments contained 0·653 and 1·18% of carbon respectively.

W. P. S.

Pure Ferric Oxide as a Standard Substance for the Estimation of Iron in Hydrochloric Acid Solution. L. Brandt (Chem. Zeit., 1908, 32, 812—814, 830—832, 840—843, 851—853).—A lengthy article, unsuitable for adequate abstraction. The chief point is the preparation of a pure oxide of iron, which may then be dissolved in hydrochloric acid, and serve for the standardising of the permanganate after the usual reduction with stannous chloride.

About 50 grams of a commercially-pure iron free from zinc are dissolved in hydrochloric acid, and a current of hydrogen sulphide is passed. The filtrate is boiled, and oxidised with nitric acid. The solution is concentrated, and evaporated twice with hydrochloric acid. The mass is dissolved in hydrochloric acid, D 1·104, and shaken repeatedly in a separating funnel with ether, which dissolves the ferric chloride. Should the iron contain cobalt, this will also pass into the ether, but may be removed by shaking the ether with 1/10 of its volume of hydrochloric acid, D 1·104, saturated with ether. The ether is evaporated, and the residual ferric chloride converted into nitrate by repeated evaporation with excess of nitric acid, and, finally, with addition of ammonium nitrate. The dry mass is now ignited in a platinum dish, finally with addition of ammonium carbonate, until the weight is constant to about 0·01 gram.

L. de K.

T. A. H.
Detection of Chromium. M. Emmanuel Pozzi-Escot (Ann. Chim. anal., 1908, 13, 333).—The solution, which, besides chromium, may contain a large excess of iron, manganese, cobalt, nickel, copper, &c., is heated to boiling, a solution of sodium hypobromite containing a large excess of alkali is added, and the boiling is continued for a few minutes. When cold, the solution is filtered, and the chromate formed is identified by the usual tests, such as lead acetate and acetic acid.

L. de K.

Estimation of Chromium and Tungsten in Steel. F. Willy Hinrichsen and Ludwig Wolter (Zeitsch. anorg. Chem., 1908, 59, 183—197).—Attempts were made to separate tungsten and chromium by precipitating the former as tungstic acid with nitric acid, but the precipitation was incomplete. On the other hand, reduction of the chromate to chromic salt and precipitation with ammonia gave too high results. Good results were finally obtained by precipitating the tungsten (and a small part of the chromium) with benzidine hydrochloride according to Knorre (Abstr., 1905, ii, 286), the amount of chromium in the precipitate being determined by oxidising to chromate and estimating with potassium iodide and thiosulphate in the usual way. With certain precautions, the presence of tungstic acid does not interfere with the iodometric estimation of chromium.

In the presence of chromium, the results for tungsten obtained by the benzidine method are somewhat too low, and this point is under investigation.

On the other hand, satisfactory results for both metals were obtained by precipitating both chromium and tungsten from an aliquot part of the solution by means of mercurous nitrate (Berzelius) and estimating the chromium in another portion of the solution by the iodometric method. The precipitation is done as follows: To a portion of the solution containing chromate and tungstate, heated to boiling, a saturated solution of mercurous nitrate is added, and then 10% ammonia added drop by drop until the precipitate becomes dark brown. The mixture is then boiled, filtered, dried, ignited, and the mixture of acids weighed.

G. S.

Estimation of Vanadium, Molybdenum, Chromium, and Nickel in Steel. Andrew A. Blair (J. Amer. Chem. Soc., 1908, 30, 1229—1233).—Two grams of the sample are converted into syrupy ferric chloride, which is then dissolved in a little hydrochloric acid, D 1·1. The solution is shaken first with 80 c.c. and then again with 50 c.c. of ether, which dissolves the iron and also the molybdenum. The ether is then shaken with water, and the aqueous solution evaporated with excess of sulphuric acid. The ferric sulphate is then dissolved in water, and reduced by boiling with ammonium hydrogen sulphite. The molybdenum is precipitated by means of a current of hydrogen sulphide, collected in a Gooch crucible, and converted into trioxide by cautious ignition. As it always contains a little iron, it is dissolved off the filter by means of dilute ammonia, and the crucible is re-weighed.

The liquid which has been extracted with ether is repeatedly
evaporated with nitric acid to a syrupy condition, dissolved in 20 c.c. of hot water, and, after reducing any chromate formed by means of sulphurous acid, poured into a boiling 10% solution of sodium hydroxide. The precipitate contains the oxides of chromium and nickel, also the bulk of the manganese, and traces of iron and copper. The filtrate, which contains the vanadium and sometimes a trace of chromium, besides any silica and alumina, is acidified faintly with nitric acid, and then again rendered slightly alkaline and boiled to remove the last traces of chromium. To the filtrate are added 10 c.c. of 10% lead nitrate and then a little acetic acid, and, after boiling for a few minutes, the lead vanadate is collected and evaporated with a large excess of hydrochloric acid to effect reduction. The hydrochloric acid is then completely expelled by evaporation with 10 c.c. of sulphuric acid, and the residue, after being diluted to 150 c.c., is titrated for vanadium at 60—70° with standard permanganate. The filters containing the two precipitates from the soda solution are burnt, and the ash fused with 2 grams of sodium carbonate and 0·5 gram of potassium nitrate. The mass is then extracted with water. The insoluble portion contains nickel, copper, iron, and part of the manganese. It is dissolved in hydrochloric acid, the copper is removed by hydrogen sulphide, and the filtrate evaporated with excess of sulphuric acid. The residue is diluted with water, excess of ammonia is added, and the nickel deposited electrolytically. The filtrate, which contains the chromium and the remainder of the manganese, is mixed with excess of ammonium nitrate and evaporated with addition of ammonia; this precipitates the manganese, also any silica and alumina. The filtrate is then boiled, reduced with sulphurous acid, and the chromium precipitated by ammonia and weighed as oxide.

L. DE K.

Estimation of Vanadium in Iron and Steel. Edward De Mille Campbell and Edwin LeGrand Woodhams (J. Amer. Chem. Soc., 1908, 30, 1233—1236).—Five grams of the sample are dissolved in dilute sulphuric acid, and the insoluble matter, which contains part of the vanadium, is collected and burnt, and finally treated with hydrofluoric acid to expel silica. The soluble portion is treated with hydrogen sulphide and evaporated to about 35 c.c., and the greater portion of the ferrous sulphate precipitated by addition of 100 c.c. of alcohol. The filtrate is oxidised with hydrogen peroxide, boiled, and precipitated with sodium carbonate. The precipitate is collected, and to it is added the residue from the first step of the analysis. The whole is fused with sodium carbonate, and then 300—400 milligrams of charcoal are added and the heating continued for ten minutes in the covered crucible. The object of the charcoal is to reduce any chromate formed; sodium vanadate is not affected.

The mass is now extracted with hot water, 10 c.c. of sulphuric acid, D 1·51, are added, and then 3—4 c.c. of 3% potassium permanganate. After boiling for five minutes, sulphurous acid is added until the permanganate has been reduced and the vanadic acid converted into the blue divanadyl sulphate. The solution is then evaporated until sulphuric fumes appear, and, when cold, water is added up to
ABSTRACTS

60 c.c. and the warm liquid titrated with $N/20$ permanganate, 1 c.c. of which $=0.00256$ gram of vanadium.  

L. de K.

Estimation of Alcohol in Fermented Liquids. WM. ANTONI (J. Amer. Chem. Soc., 1908, 30, 1276—1278).—The wine or other alcoholic liquid is introduced into a specially constructed pyknometer of the Sprengel type, brought to the required temperature by immersion in a bath, and weighed. By means of a rinsing arrangement, the wine is introduced into the distilling flask, and the distillate is collected in the pyknometer, which is then carefully filled up with water and re-weighed. For details, the original paper and illustrations should be consulted.  

L. de K.

Detection of Formaldehyde. FRANZ VON FILLINGER (Zeitsch. Nahr. Genussm., 1908, 16, 226—231).—The paper is written with the object of drawing general attention to the usefulness of the test described by Hehner for the detection of formaldehyde. The author discusses the chemistry of the reaction (compare Abstr., 1907, ii, 512), and gives general directions for its application.  

W. P. S.

Bang’s method gives good results with pure sugar solutions, but not with urines. Borchardt’s suggestion, that diabetic urine contains an unknown laevorotatory sugar, is not accepted.  

J. J. S.

Estimation of Reducing Sugars. FRITZ ZERBAN and W. P. NAQUIN (J. Amer. Chem. Soc., 1908, 30, 1456—1461 *).—The cuprous oxide formed by the action of the reducing sugar on Fehling’s solution is collected in a Munro-Neubauer crucible, and the precipitate is converted into copper oxide by heating for ten minutes over a Bunsen flame.

In some cases there may be present co-precipitated mineral matter; the real amount of copper oxide must then be estimated by some accurate method, such as Low’s volumetric process.

Some sugars contain reducing substances other than sugar. In such cases, clarification with normal lead acetate is resorted to, which will partly remove such matters.  

L. de K.

Detection and Identification of Certain Reducing Sugars by Condensation with $p$-Bromobenzylhydrazide. E. C. KENDALL and HENRY C. SHERMAN (J. Amer. Chem. Soc., 1908, 30, 1451—1455).—The reagent is prepared by heating on a water-bath a mixture of 10 grams of ethyl $p$-bromobenzoate, 8.2 grams of a 50% aqueous solution of hydrazine hydrate, and 12 c.c. of 95% alcohol. After four hours, the alcohol is distilled off, and the residue, after being washed with ether, is recrystallised from alcohol.

The test is applied by heating about $0.03$ gram of the sugar with

* and Bull. Assoc. chim. Sucr. Dist., 1908, 26, 177—182.
twice its weight of the reagent in presence of alcohol. After evaporating three or four times with alcohol, the residue is boiled with chloroform and a few drops of water, which leaves the condensation product undissolved. The reaction is obtained with dextrose, galactose, mannose, and arabinose; not with l€€vulose, maltose, or lactose, and only to a slight extent with xylose.

The $p$-bromobenzylhydrazone of galactose is insoluble in boiling alcohol, those of mannose and arabinose are dissolved partly, whilst that of dextrose is completely dissolved. The non-reacting sugars, however, interfere with the formation of the dextrose hydrazone to an extent comparable with the interference of maltose and lactose in the ordinary osazone reaction for dextrose.

L. de K.

Test for Pentoses with Orcinol and Hydrochloric Acid. J. Pieraerts (Bull. Assoc. chim. Suer. Dist., 1908, 26, 46—62).—Sugars with a keto-group, such as l€€vulose, produce colorations with orcinol and hydrochloric acid which obscure the colour given by pentoses; hence l€€vulose and its anhydrides should first be eliminated by fermentation with yeast. In employing the orcinol reagent of Tollens, it is advisable to add an additional volume of concentrated hydrochloric acid to the mixture of one volume of the reagent with one volume of the pentose solution.

G. B.

Formic Acid in Glacial Acetic Acid. H. Ost and F. Klein (Chem. Zeit., 1908, 32, 815—816).—Wegener's process for formates is recommended. Ten c.c. of the sample are heated with 50 c.c. of sulphuric acid in a flask from which the air has been expelled by a current of carbon dioxide. The mixture is heated on the water-bath for one hour, and the gas evolved collected, with the usual precautions, over aqueous potassium hydroxide; 100 c.c. of carbon monoxide = 0·2056 gram of formic acid.

Good results are also obtainable in the case of weaker acids with Lieben's permanganate or Macnair's dichromate process, or with the mercuric chloride reduction method.

L. de K.

Estimation of the Acidity of Wines. G. Favrel (Ann. Chim. anal., 1908, 13, 315—316).—Three official methods are in use. Titration with sodium hydroxide, using phenolphthalein as indicator; the same, using red litmus paper; titration with lime water until a grey, flocculent precipitate forms. The author states that there is a great discrepancy between the results obtained by the first and the last two methods, and expresses the hope that analysts will adopt a definite process.

L. de K.

Indirect Estimation of the Acidity of Wines. G. Favrel (Ann. Chim. anal., 1908, 13, 343—346).—Ten c.c. of the wine free from carbon dioxide are placed in a separating funnel, and 20 c.c. of $N/20$ sodium hydroxide free from carbonate are added. A quantity of benzoic acid, known from a previous experiment to neutralise exactly the soda, is introduced, and the whole is well shaken. The liquid, which now contains free benzoic acid equivalent to the acidity of the
wine, is shaken twice in succession with 40 c.c. of ether, and this is slowly distilled until about 20 c.c. are left. The residue is allowed to evaporate in a beaker, and the flask is rinsed first with 10 c.c. and then with 5 c.c. of alcohol, which is poured into the beaker. The alcoholic solution is then titrated with N/20 sodium hydroxide, using phenolphthalein as indicator.

New Method of Estimating the Fixed and Volatile Acids in Wine. M. Emmanuel Pozzi-Escot (Compt. rend., 1908, 147, 245—247; Bull. Soc. chim. Belg., 1908, 22, 338—340; Bull. Assoc. chim. Suer. Dist., 1908, 26, 68—69).—The method is based on the transformation of the barium salts of the fixed acids into carbonates by suitable heating and titration of these by standard acid. Two samples, each of 100 c.c., are concentrated to 3—4 c.c. in flat porcelain capsules. The product of the first is treated with an excess of alcohol, filtered, and the filter calcined in a muffle furnace. The alkalinity of the ash is determined by titration with standard nitric acid, using methyl-orange as indicator. The second sample, after evaporation, is neutralised with baryta, and treated with 100 c.c. of a 2% solution of barium bromide in alcohol (96%). The barium salts of the fixed organic acids (except lactic acid) are precipitated immediately and completely; they are filtered off, washed with strong alcohol (in which the barium salts of the volatile acids are soluble), drained, and calcined in a porcelain capsule in a muffle furnace. The carbonates formed are titrated against standard nitric acid, and the result, after deduction of the value obtained from the first experiment, corresponds with the acidity of the wine due to the fixed acids. Subtraction of the acidity due to the fixed acids from the total acidity of the wine, determined on 100 c.c., using phenolphthalein as indicator, gives the acidity due to the volatile acids. The author claims that the method is rapid and simple. It is only applicable to the estimation of organic acids, and is inexact in the presence of lactic acid, but the presence of the latter in wines is quite exceptional.

The Natural Citric Acid of Wine. E. DuPont (Ann. Chim. anal., 1908, 13, 338—343).—A study of the Denigès mercury test for citric acid. Most wines from the South of France give the reaction, but, unless they are preserved by mean of sulphur dioxide, the acid disappears within a few months. The author thinks the reaction may be made approximately quantitative. As comparison liquid should be used a wine itself free from citric acid, but to which a known quantity of the acid has been added.

Estimation of Malic Acid in Food Products. H. W. Cowles, jun. (J. Amer. Chem. Soc., 1908, 30, 1285—1288).—The process is devised for the estimation of malic acid in maple products, but may, of course, be applied to other products, such as cider, cider vinegar, etc. 6.7 Grams of the sugar or syrup are dissolved in 5 c.c. of water, and 2 c.c. of 10% calcium acetate are added, followed by 100 c.c. of 95% alcohol, and the whole is warmed on the water-bath until the precipitate has settled completely. The precipitate is washed free from soluble
matters with 85% alcohol and then burnt to carbonate. This is then estimated as usual by dissolving in \(N/10\) hydrochloric acid and titrating back with \(N/10\) sodium hydroxide. The alkalinity represents the malic acid.

L. de K.

Estimation of Tartaric Acid in the Presence of Malic and Succinic Acids. L Gowing-Scoopes (Analyst, 1908, 33, 315—319).—The author has submitted the method proposed by Ferentzy (Abstr., 1907, ii, 991) to a critical examination, and finds that it is trustworthy. It is stated, however, that more accurate results may be obtained by titrating the magnesium basic tartrate with potassium permanganate than by igniting it as recommended by Ferentzy. The method may be applied to the estimation of tartaric acid in fruit juices, and in wines if the tannic acid is first removed.

W. P. S.

J. V. E.

A New Process for the Estimation of Lactic Acid in Organs and Animal Fluids. I. Estimation of Lactic Acid in Aqueous Solutions. Ernst Jerusalem (Biochem Zeitsch., 1908, 12, 361—378).—The lactic acid is estimated by oxidising to acetaldehyde: \(\text{CH}_3\cdot\text{CH}(	ext{OH})\cdot\text{CO}_2\text{H} + \text{O} = \text{CH}_3\cdot\text{CHO} + \text{CO}_2 + \text{H}_2\text{O}\), and estimating the aldehyde thus formed by treating with excess of iodine in alkaline solution, and afterwards estimating the excess not used for the formation of iodoform from the aldehyde. To get trustworthy results, the oxidation must be carried out by warming the liquid containing the lactic acid with sulphuric acid, and adding permanganate solution to the boiling mixture. The aldehyde as it is formed must be removed as quickly as possible from the boiling liquid; this is accomplished by means of a current of air. The apparatus for the absorption of the aldehyde must also be very efficient, and one, specially devised, is figured in the original paper. In animal tissues, other substances are found which will interfere with the accuracy of the determinations, especially the sugars and acetone. Tissues must therefore be evaporated down and extracted with ether, and the lactic acid estimated in the ethereal extract.

S. B. S.

A New Process for the Estimation of Lactic Acid in Organs and Animal Fluids. II. Estimation of Lactic Acid in Animal Fluids. Ernst Jerusalem (Biochem. Zeitsch., 1908, 12, 379—389).—In estimating the lactic acid in animal tissues and liquids, the acid must be first extracted with ether (see preceding abstract). Quantitative extraction can only be accomplished when the liquid to be extracted is so concentrated as to be of pasty consistency. A special apparatus for the extraction of such liquids is figured and described in
the paper, and also the application of the method to special cases, such as the estimation of lactic acid in blood, milk, urine, &c. S. B. S.

Detection and Estimation of Boric Acid, Salicylic Acid, and Benzoic Acid in Foods, etc. Wilhelm von Generisch (Zeitsch. Nahr. Genussm., 1908, 16, 209—225).—The results of a critical examination of many of the methods proposed for the detection and estimation of these acids are given. Amongst others, the method described by Windisch (Abstr., 1905, ii, 554) was found to be trustworthy for the estimation of boric acid, as was also Freyer's iodometric process for estimating salicylic acid. Benzoic acid is best extracted from food materials by means of benzene, or mixtures of the latter with light petroleum. The benzene solution of the acid may be evaporated after the addition of ammonia, or a portion of it may be titrated with standard alkali solution.

Detection of Benzoic Acid in Butter. Georges Halphen (J. Pharm. Chim., 1908, [vi], 28, 201—203 *).—The test proposed is a modification of that described originally by Mohler, in which the benzoic acid is converted into ammonium diaminobenzoate; this salt, when treated with alkalis, gives a brownish-red coloration. The butter to be tested is melted, together with sufficient lime-water, to render the aqueous portion distinctly alkaline; after cooling, the aqueous portion is separated, rendered acid with phosphoric acid, and shaken out with ether. The ethereal extract is evaporated at the ordinary temperature, and the dry residue is dissolved in 2 c.c. of sulphuric acid, the mixture being heated slightly to dissolve the benzoic acid. When cold, 0.2 c.c. of fuming nitric acid is added, the solution is transferred to a test-tube, and heated, with constant agitation, over a small flame until it boils. The heating is then continued, without agitating the contents of the tube, until sulphuric acid vapours commence to be evolved. After cooling, 6 c.c. of water are added, and then saturated sodium sulphite solution, drop by drop, until all the yellow vapours have disappeared. Ammonia is then allowed to flow over the surface of the liquid, when, if benzoic acid is present, an orange-red coloration is obtained, the intensity of which depends on the quantity of benzoic acid in the sample.

Separation and Estimation of Salicylic Acid and Methyl Salicylate; Hydrolysis of Methyl Salicylate. H. D. Gibbs (J. Amer. Chem. Soc., 1908, 30, 1465—1470).—Estimation of Free Salicylic Acid in Oil of Gaultheria.—Five to twenty c.c. of the ester are shaken with an equal volume of water, and titrated with $N/50$ sodium hydrogen carbonate, using Congo-red as indicator.

Preparation and Estimation of Salicylic Acid and Methyl Salicylate in Foods and Drugs.—The substance is extracted with $N$-sodium hydrogen carbonate, which dissolves the salicylic acid and also a portion of the ester; the remaining ester is recovered by acidifying with dilute sulphuric acid, and distilling in a current of steam; the ester is then shaken out with chloroform. The filtrate is shaken with chloroform to remove the dissolved ester, and the salicylic acid is

recovered from the alkaline solution by acidifying and shaking with chloroform; finally, the acid is determined colorimetrically.

The chloroform extracts containing the ester are boiled in a reflux apparatus with excess of potassium hydroxide, and the salicylic acid formed is then estimated as directed.

For the methods of studying the rate of saponification of the ester by sodium hydroxide and carbonate, the original article and curve should be consulted. Methyl salicylate, on keeping, always becomes slightly hydrolysed.

L. de K.

Characteristic Test for Hippuric Acid [in Urine]. William M. Dehn (J. Amer. Chem. Soc., 1908, 30, 1507—1508).—A few c.c. of the urine are treated in a test-tube with sodium hypobromite just sufficient to decompose the carbamide and impart a permanent, yellow colour. The solution is then heated to boiling, when, should hippuric acid be present, an orange or brownish-red precipitate is formed, which, however, consists partly of earthy phosphates.

The nature of the red precipitate, which contains nitrogen and bromine, has not yet been fully investigated. It is soluble in most of the organic solvents and in carbon disulphide.

L. De K.

Apparatus for Estimating the Expansion of Oils and Other Liquids which Boil above 100°. Wilhelm Thörner (Chem. Zentr., 1908, i, 2001—2003; from Zeitsch. chem. Apparatenkunde, 1908, 3, 165—168).—The estimation of the expansion of oils and fats between 0° and 100° is advised as an additional means of identification. A Jena glass flask, having a long neck, which is graduated in 1/10 c.c. from the top downwards, and having a capacity of exactly 100 c.c. of distilled water at 100°, is nearly filled with the oil to be tested. The flask is then heated in a suitably arranged steam jacket to 100°, when the volume is made up exactly to the zero mark. The flask and contents are then placed in an ice-chest to cool down to 0°, when the difference in volume may be observed on the graduated neck of the flask. A table of results obtained with thirty-three substances is given, and it is shown that by this method the amount of acetic acid in water solutions may be estimated with a fair degree of accuracy.

J. V. E.

A New Reaction for Distinguishing between Heated and Unheated Milk, and for the Detection of Hydrogen Peroxide in Milk. W. Percy Wilkinson and Ernest R. C. Peters (Zeitsch. Nahr. Genussm., 1908, 16, 172—175).—The test is similar to the well-known p-phenylenediamine test, but benzidine is used in place of the latter. Ten c.c. of the milk to be tested are treated with 2 c.c. of a 4% alcoholic benzidine solution, from two to three drops of acetic acid, and 2 c.c. of a 3% hydrogen peroxide solution. With unheated milk, a blue coloration appears at once, whilst if the milk has been heated to a temperature of, or exceeding, 78°, no change in colour takes place. The test is stated to be more sensitive than the p-phenylenediamine reaction, and may be used, conversely, for the detection of hydrogen peroxide.

W. P. S.
Detection of Small Quantities of Turpentine in Lemon Oil. E. M. CHACE (J. Amer. Chem. Soc., 1908, 30, 1475—1477).—Fifty c.c. of the sample are distilled in a Ladenburg 3-bulb flask. The first 5 c.c. of the distillate are mixed with an equal volume of glacial acetic acid and cooled in a freezing mixture, 5 c.c. of ethyl nitrite are added, and, after mixing, 2 c.c. of strong hydrochloric acid are added drop by drop. After fifteen minutes, the deposit is collected on a Büchner funnel, using filter-paper under vacuum. The crystals are washed with about 50 c.c. of 95(vol.)% alcohol, and the filtrate is replaced in the freezing mixture in order to obtain a second crop of crystals; after passing the liquid through the same filter, the crystals are washed with strong alcohol and dried.

The crystals are now dissolved in a small quantity of chloroform, and hot methyl alcohol is added until crystallisation sets in, when the liquid is cooled. More methyl alcohol is then added, and the crystals are collected. For microscopical examination, they may be mounted in olive oil. Turpentine yields very characteristic crystals.

L. DE K.

Some Reactions of Terpin. E. ISNARD (Ann. Chim. anal., 1908, 13, 333—334).—Action of Reagents on Crystallised Terpin.—Moistened on a watch-glass with sulphuric acid, a coloration varying from chrome-yellow to salmon-rose is developed. At the same time, the terpin dissolves and emits a characteristic, aromatic resinous odour. On adding a 10% solution of sodium hydroxide, the colour disappears, but the odour becomes still more pronounced. Syrupy phosphoric acid behaves similarly, but no coloration is noticed until heat is applied. If terpin is dissolved in sulphuric acid and then acted on with nitric acid, a yellow coloration is observed, with formation of brown streaks; the solution then becomes colourless and resinified. If nitric acid is added first, the terpin dissolves to a colourless solution, but if now a drop of sulphuric acid is put on the centre, a red spot is formed surrounded by a salmon-rose zone. Terpin shows reducing properties, reducing molybdiic and chromic acids in presence of sulphuric acid, and also an acid solution of ferric chloride and potassium ferricyanide.

Action of Reagents on the Alcoholic Solution of Terpin.—Sulphuric acid turns salmon-rose, whilst the alcoholic solution remains colourless. The coloration disappears on shaking, unless the solutions are very concentrated. With a solution containing 200 c.c. of 15% ammonium molybdate, 10 c.c. of sulphuric acid, and 30 c.c. of nitric acid, a blue coloration is obtained, which takes a long time to develop. After about an hour, it becomes indigo-blue, and after twenty-four hours it has changed to bluish-green. The colouring matter is soluble in chloroform. A white deposit is also formed, but this is probably ammonium molybdate precipitated by the alcohol. When heat is applied, the coloration is developed more rapidly, but soon fades; in this case, the characteristic odour is also noticed.

L. DE K.
General and Physical Chemistry.

Ultraviolet Spectrum of Silicon. Antoine de Gramont and Charles de Watteville (Compt. rend., 1908, 147, 239—242).—The ultraviolet spectrum of silicon containing both lines and bands has been mapped between \( \lambda 2123.0 \) and \( \lambda 2987.8 \). The spectrum of the oscillating spark passing between silicon poles in hydrogen in a quartz tube gave 23 lines and 14 bands, whereas the flame spectrum obtained by burning ordinary gas impregnated with silicon chloride vapour contained 26 bands and 11 lines. The relative intensities of lines and bands common to both spectra were not the same.

The oscillation frequencies of the bands seem to fall into series, but the heads are ill-defined.

R. J. C.

Dispersion in the Electric Spectra of Benzene, Toluene, and Acetone. A. R. Colley (J. Russ. Phys. Chem. Soc., 1908, 40 (Phys.), 228—244).—The author has investigated the electrical spectra of benzene, toluene, and acetone, a method being used which permits of accurate measurements with small troughs in the case of liquids with low refractive indices. The results, which are given in the form of tables and curves, bring out the intimate chemical relationship between toluene and benzene, two bands being common to the two spectra. Further, the spectra of toluene and acetone also exhibit one common band, which must be regarded as typical for the methyl group.

T. H. P.

Discontinuous Cathode Luminescence Spectra of Some Aromatic Compounds. Otto Fischer (Zeitsch. wiss. Photograph. Photophysik. Photochem., 1908, 6, 305—326. Compare Goldstein, Abstr., 1904, ii, 689, 690).—The emission spectra of the substances exposed to cathode rays at the temperature of solid carbon dioxide were photographed. Difficulties were found in certain cases, owing to the rapid change of colour of some substances under the influence of cathode rays. The ultraviolet spectra were not examined.

The number of luminous bands is with most aromatic substances considerable. In all the cases examined, the sharp edges of the bands are turned towards the red, the blue side being more or less indistinct. It is frequently possible to group the bands in series, corresponding pairs of which show a constant difference of wave-length.

In the case of naphthalene compounds, blue and violet light is only emitted for a short time, the colour changing to yellow or red. Three characteristic blue bands of naphthalene reappear in the spectra of all the naphthalene derivatives examined, and also in those of diphenyl and phenanthrene, but, whilst the last two compounds continue to emit these bands, the structure producing them is rapidly destroyed by the bombardment in the case of naphthalene derivatives. The same
bands appear, strongly shifted towards the red, in anthracene and dibromoanthracene.

C. H. D.

Influence of Temperature and of the State of Aggregation on the Absorption Spectra of Molten Salts. T. Retschinsky (Ann. Physik, 1908, [iv], 27, 100—112).—An examination of the absorption spectra of some thirty molten inorganic salts has shown that, in all cases, there is a well-defined limit to the absorption band on the ultra-violet side of the spectrum, all radiations of smaller wavelength than that corresponding with the limiting value being completely absorbed. With rise of temperature, this limit is displaced in the direction of greater wave-lengths. When the displacement is expressed in terms of wave-lengths, its magnitude, for a given rise of temperature, increases with the wave-length; when expressed in terms of frequencies, the displacement is independent of the wave-length. For a temperature rise of 100°, the absorption limit is displaced to an extent represented by 10 to 20 x 10⁶/µµ. Some of the salts have been also investigated in the solid state. The influence of temperature on the absorption limit is of the same order of magnitude as in the case of the molten substances. On liquefaction, the absorption limit is displaced considerably in the case of the chlorides and bromides of potassium and sodium, but no sharp change is met with in the case of silver nitrate, silver chloride, or lead chloride. In regard to the influence of chemical composition on the absorption, it is found that the salts of the heavy metals absorb more than those of the alkali and alkaline-earth metals. In general, for a given metal the sulphate absorbs most light; then follow the chloride, bromide, iodide, and nitrate with gradually decreasing absorptions. For salts of the same acid containing metals belonging to the same group of the periodic system, the absorption limit is nearer the red end of the spectrum the greater the atomic weight of the metal.

H. M. D.

Fluorescence of Sodium Vapour. Hans Zickendraht (Physikal. Zeitsch., 1908, 9, 593—603).—The thermal and electrical condition of fluorescing sodium vapour has been examined. In contact with air, fluorescence begins at 280—290°; this temperature is independent of the pressure, although the sharpness with which the phenomenon sets in is much greater at higher pressures than at low. Measurements have been made of the minimum potential required for electrical discharge through the vapour under different conditions. For sodium vapour in contact with air, the potential temperature curves show minima at 240° and 280°; the latter is supposed to correspond with the commencement of fluorescence. In contact with nitrogen and carbon dioxide, the minimum potential differences corresponding with this are 300° and 340° respectively. In contact with hydrogen, an olive-coloured fluorescence can be observed at 370°, but no current could be passed through the vapour with the available potential of 400 volts.
The properties of the vapour in contact with air have been examined in greater detail. Curves are plotted which show the dependence of the current on the discharge potential under different pressures, and also the dependence of the potential on the pressure and on the temperature for a given current intensity. When a current has been passed through the vapour for some time, a smaller potential is required for discharge immediately after the cessation of the current than when some time has elapsed. The potential gradually increases, and attains a constant value after some minutes. The paper concludes with a theoretical discussion of the cause of the conducting power of sodium vapour.

H. M. D.

Fluorescence of Organic Substances. Johannes Stark and W. Steubing (Physikal. Zeitsch., 1908, 9, 661—669. Compare Abstr., 1907, ii, 147, 417; this vol., ii, 138, 746).—Further observations relating to the fluorescence of substances containing chromophoric groups are communicated, and a summary is given of the results obtained in the series of papers published by Stark on the connexion between fluorescence and absorption.

The new substances examined were acetone, methyl ethyl ketone, pyrotaurartic acid, phorone, diacetyl, camphor, camphorquinone, dimethylfulven, potassium azodicarboxylate, azodicarbonamide, diethylketen, and diphenylketen. From the observations, the conclusion is drawn that if a substance possesses two absorption bands, one in the region of longer wave-lengths, the other in the remote ultraviolet region, it will fluoresce in the region of the first band when light is absorbed in the region of the second. The fact that the maxima for the intensity of the fluorescence and absorption do not coincide is due to the absorption which the fluorescent light undergoes in its passage through the absorbing medium. The two azo-compounds investigated are exceptions to this general statement, but this is supposed to be due to the absence of the radiation of the requisite very short wave-lengths from the aluminium light used in the experiments.

H. M. D.

Ultraviolet Fluorescence of Cyclic Compounds. Heinrich Ley and K. von Engelhardt (Ber., 1908, 41, 2988—2995. Compare Stark, Abstr., 1907, ii, 147; Stark and Meyer, ibid., ii, 418).—The ultraviolet fluorescent, and the absorption, spectra of mono- and di-substituted benzene derivatives in ethyl-alcoholic solutions of NO·005 concentration have been measured in an apparatus very similar to that used by Stark; the results confirm this investigator’s theory of the relation between fluorescence and selective absorption.

Toluene and propylbenzene are more strongly fluorescent than benzene, and the four bands which characterise the fluorescent spectrum of benzene have disappeared in the spectra of these two homologues. The auxochromic influence of the amino-group is accompanied by an auxofluoric influence, since aniline is more fluorescent than benzene; dimethylaniline, however, is less fluorescent than aniline, although the contrary might be expected from Kaufmann’s
view that the dimethylamino-group is a stronger auxochrome than the amino-group. The hydroxyl and the methoxyl groups also act as auxofluors, phenol and anisole exhibiting a remarkably strong fluorescence, whilst the very feeble fluorescence of benzoic acid is markedly increased in the hydroxybenzoic acids, of which the ortho-compound fluoresces most strongly, even in the visible region, as is evident to the naked eye, when a quartz lamp and a quartz vessel are used. Although anisole is more fluorescent than phenol, the methoxybenzoic acids are less so than the hydroxy-acids; the fluorescence of p-methoxybenzoic acid cannot be detected with certainty. The introduction of a halogen into the benzene nucleus diminishes the fluorescence, the more so the greater the molecular weight; iodo-benzene does not fluoresce. Benzamidine is non-fluorescent, showing that the amino-group only has auxofluoric influence when situated in the nucleus.

The presence of a nitro-group often entirely prevents fluorescence, even although o- and p-nitrophenols and o-nitroaniline exhibit marked selective absorption (according to Stark’s theory, fluorescence is conditioned by the presence of bands in the absorption spectrum). The non-fluorescence may be attributable to quinonoid structure (compare Baly, Edwards, and Stewart, Trans., 1906, 89, 514; Hantzsch, Abstr., 1906, i, 353), since simple quinones never fluoresce.

Neither pyridine nor ethyl collidinedicarboxylate exhibit fluorescence. Ethyl dihydrocollidinedicarboxylate, however, shows violet fluorescence in alcoholic solution, and also a very intense band; thus providing a good confirmation of Stark’s theory.

C. S.

Natural and Magnetic Rotation of the Plane of Polarisation in Crystals. Waldemar Voigt and K. Honda (Physikal. Zeitsch., 1908, 9, 585—590).—Measurements of the natural rotation of the plane of polarisation for a series of wave-lengths are recorded for d- and l-sodium chlorate and d-tartaric acid in the direction of the optic axis, and for sucrose in the direction of the two axes. The rotation induced by a strong magnetic field was measured for sodium chlorate, dolomite, apophyllite, apatite, and sucrose. In the case of sucrose, the values obtained for the two optic axes indicate that the magnitude of the rotation of the plane of polarisation is different in the two directions.

H. M. D.

Relation between Rotatory Power and Chemical Constitution. II. D. Hardin (J. Chem. Phys., 1908, 6, 584—591. Compare this vol., ii, 470).—The theoretical deductions given in the previous paper have been further tested by application to certain derivatives of hexyl alcohol.

The atomic product for oxygen (the product of the distance between the oxygen and carbon atoms and the atomic weight of the former element) is approximately the same as that calculated from observations on the amyl derivatives, but is of opposite sign. The difference of sign has not been satisfactorily accounted for.
The theory also indicates that the distance between the centre of gravity of the benzene ring and the first carbon in the side-chain will be different according as the bonds between carbon and hydrogen are in the plane of the ring or perpendicular to it. The experimental data obtained with hexylbenzene support the latter view as to the structure of the benzene nucleus.

Active hexyl alcohol (γ-methylamyl alcohol) was prepared by saponification of Roman camomile oil with cold concentrated potassium hydroxide solution and repeated fractionation. The fraction boiling at 151—152°/758 mm. has D\textsuperscript{20} 0·8262, [α]\textsubscript{D}\textsuperscript{20} +8·77°, D\textsuperscript{20} 0·7812, [α]\textsubscript{D}\textsuperscript{20} 7·53°, and D\textsuperscript{16} 0·7276, [α]\textsubscript{D} 6·10°. The corresponding bromide has D\textsuperscript{19} 1·1852, [α]\textsubscript{D}\textsuperscript{19} +19·97°, D\textsuperscript{19} 1·1150, [α]\textsubscript{D}\textsuperscript{19} 17·12°, and D\textsuperscript{14} 1·0319, [α]\textsubscript{D}\textsuperscript{14} 13·97°. Active hexylbenzene (α-phenyl-γ-methylpentane) (compare Klages and Sautter, Abstr., 1904, i, 302), prepared by the action of sodium on a mixture of bromobenzene and hexyl bromide, has D\textsuperscript{19} 0·8521, [α]\textsubscript{D}\textsuperscript{19} +16·62°, D\textsuperscript{19} 0·7873, [α]\textsubscript{D}\textsuperscript{19} 14·99°, and D\textsuperscript{18} 0·7396, [α]\textsubscript{D}\textsuperscript{18} 13·66°.

G. S.

Optical Isomerides. I. Iwan Ostromisslensky (Ber., 1908, 41, 3035—3046).—The observations of Gernez on the separation of a dl-conglomerate by means of the addition of a fragment of a substance isomorphous with one of the components have been extended.

The addition of l-asparaginé to a supersaturated solution of dl-sodium ammonium tartrate causes the deposition of the pure d-tartrate.

Both d-tartrate and l-asparagine are hemihedral forms belonging to the rhombic system, and are isomorphous.

An optically active salt can also be obtained by impregnating a supersaturated solution of dl-sodium ammonium tartrate with a crystal of an active modification of any other alkali tartrate; for example, Rochelle salt, potassium tartrate, sodium tartrate, potassium hydrogen tartrate. In all cases the salt which is deposited is dextroto, and lÆvo if this is lævorotatory. Inoculation with ordinary ammonium malate causes the deposition of d-sodium ammonium tartrate. Substances which are isomorphous with the sodium ammonium tartrate can also be used for bringing about the separation. Thus a crystal of d-potassium ammonium tartrate (usually monoclinic) causes the deposition of d-sodium ammonium tartrate, and similarly with potassium tartrate.

It is not necessary that the material used for inoculation should be optically active; thus glycine added to a supersaturated solution of dl-asparaginé causes the deposition of either d- or l-asparaginé, and it is not possible in any given experiment to predict which of the two will separate from an inspection of the glycine crystals, although the same glycine crystal always acts in the same way. The conclusion is drawn that glycine belongs to the hemihedral class of rhombic prisms.

This method of deposition is suggested as a method for determining whether the given substance is a dl-conglomerate or a r-compound.

If the crystals deposited on impregnating with an isomorphous substance are found to be inactive, then the original solution contained
a racemic compound, but if active, then the original was an inactive conglomerate.

J. J. S.

Chemical Action of Light. GIACOMO L. CIAMICIAN (Bull. Soc chim., 1908, [iv], 3, i—xxvii).—A lecture delivered before the French Chemical Society.

E. H.

Chemical Action of Tropical Sunlight. GILBERT JOHN FOWLER (Mem. Manchester Phil. Soc., 1908, 52, xiv, 1—20).—Observations are recorded on the rate of liberation of iodine from an acidified potassium iodide solution under the influence of light. The reaction is practically unaffected by temperature under the ordinary conditions of exposure. The rate of liberation of iodine from a given solution diminishes with the duration of the exposure; this is due to the absorption of the chemically-active rays by the iodine liberated previously. The initial rate of liberation diminishes with increasing dilution of the solution, but, on longer exposure, results in closer agreement are obtained, owing, no doubt, to the greater retarding effect of the iodine liberated from the stronger solutions.

Tables of data obtained by measurements made in Calcutta and on the Mediterranean and Arabian Seas are recorded. The highest record corresponds with an actinic effect which is forty-two times as great as the lowest record obtained on a bright December day in Manchester. No relationship appears to exist between the photochemical and the sun-stroke effect of sunlight.

Solutions of bleaching powder lose their available chlorine with great rapidity on exposure to tropical sunlight. The effect is much more marked in the case of dilute solutions than it is in strong solutions.

Silver chloride, sealed in a glass tube and darkened by exposure to light, becomes quite white again when kept for some time in the dark. In the presence of a globule of mercury, the original colour is not restored. These observations support the view that the darkening of silver chloride on exposure to light is a dissociation effect, and is not due to the formation of an oxychloride.

H. M. D.

Photochemical Reactions. III. Decomposition of Ozone by Light. FRITZ WEIGERT (Zeitsch. Electrochem., 1908, 14, 591—597).—The decomposition of ozone by light in presence of chlorine (this vol., ii, 5) is studied quantitatively. The light of a mercury quartz lamp is used, and the rate of decomposition measured by means of the change of pressure of the gas. There is no induction period, and decomposition stops when the light is cut off. The rate of decomposition is independent of the concentration of the ozone; it increases with the concentration of the chlorine, but not in proportion to it, and it is nearly proportional to the intensity of the light. By placing a vessel containing chlorine between the source of light and the ozone tube, a measurement of the quantity of light absorbed by the chlorine is obtained; in this way it is shown that the rate of decomposition of the ozone is proportional to the quantity of light absorbed by the chlorine mixed with it. A rise of temperature of 10° increases the rate of reaction 1·17 times
It is suggested that the light produces some intermediate product which is destroyed rapidly by the action of ozone; the rate of decomposition measured is then the rate of formation of this product, which is independent of the concentration of the ozone.  T. E.

Catalytic Reactions and Photochemical Equilibria.  Bartolo L. Vanzetti (Atti R. Accad. Lincei, 1908, [v], 17, ii, 285—288).—The author has carried out experiments to ascertain whether catalytic action necessitates immediate contact of the catalyst and the substance acted on, or whether the action can take place at a distance. When detonating gas is separated from platinum-black by a sheet of glass, the thickness of which is of the same order of magnitude as the wavelength of light, no combination occurs between the hydrogen and oxygen. But when the separating layer consists of an organic material, such as gelatin or a colloid, the hydrogen and oxygen combine slowly, but combination is found to be preceded by diffusion of the mixed gases through the membrane, as is shown by the observation that the diminution of the gas volume per unit of time is proportional to the concentration (pressure) of the gas mixture (compare Ernst, Abstr., 1901, ii, 495).

Experiments with platinum and platinum-black placed at a distance of 0.5—1 mm. from rapid bromide plates show that both these substances exert a negative action on the plate, that is, they take away the darkening produced in the sensitive emulsion by the action of light (compare Piltschikow, Abstr., 1906, ii, 414). This action is, however, quite different from that of light, and from the Russell effect produced by certain metals, in that it is only manifested at the surface of the photographic film and penetrates the latter only very slowly. This negative effect of platinum is especially marked in moist air, is greatly diminished in a cathode-ray vacuum, and is not exhibited in air in presence of phosphoric oxide. Experiments with other metals show that these may be arranged in the following series, in the first part of which the metals exhibit a diminishing positive effect on a photographic plate, whilst in the latter part an increasing negative effect is produced: cadmium, zinc, aluminium, lead, iron... copper, tin, silver, palladium, iridium, nickel, gold, platinum. If the condition in a silver bromide plate is represented as an equilibrium between the two reactions \( 3\text{AgBr} \rightarrow \text{Ag}_2\text{Br} + \text{AgBr}_2 \), the upper of which is produced by the action of light, and the lower by the action of darkness, the action of platinum at a distance is to accelerate the latter change.

T. H. P.

Chemical Changes Produced by Different Kinds of Rays.  I. Catalytical Reactions of Sunlight.  Carl Neuberg (Biochem. Zeitsch., 1908, 13, 305—320).—A large number of substances undergo chemical change when exposed in solution to sunlight in the presence of uranium salts. The following changes have been observed: Alcohols to aldehydes; poly-alcohols to hydroxy-aldehydes or ketones; acids to aldehydes or keto-compounds, sometimes with fewer carbon atoms than the original substance; monosaccharides to osones; disaccharides undergo inversion; polysaccharides and glucosides are
hydrolysed; amino-acids undergo deamidisation and lose carbon
dioxide, yielding aldehydes with a smaller number of carbon atoms
than the original substance; glycerides are partly hydrolysed; peptones
and proteins are partly hydrolysed, and the hydrolysis products undergo
the fuller changes noted above.

Amongst the products actually isolated by decomposition in sunlight
in presence of uranium salts were: glycerose in the form of the
osazone, m. p. 130—131°, from glycerol; glyoxal in the form of the
p-nitrophenyllosazone from tartaric acid; acetaldehyde (in the form of
the p-nitrophenylhydrazone) from alanine, from which ammonia was
also obtained; dextrose (in the form of the osazone) from inulin.

S. B. S.

Theory of Coloured Salts. Hermann Fecht (Ber., 1908, 41,
2983—2987).—The depth of the colour of many aromatic additive
compounds appears to be conditioned by the magnitude of the difference
of the electrical character of the two components; the more positive
the one and the more negative the other, the deeper the colour. For
example, quinone + phenol is red, quinone + sodium phenoxide is
blue, and quinone + aniline in cold carbon disulphide yields a mass
of dark violet crystals, which becomes colourless when the aniline is
washed away. Again, diphenyldi-imine + benzidine gives a yellow
solution, which becomes blue when the quinonoid component is made
more negative by salt formation; the blue colour vanishes when the
other component also enters into salt formation. Malachite-green
becomes blue when chlorine is introduced into the phenyl group, and
yellow when the halogen is attached to the still basic nitrogen atom.
The effect on colour of the halogen atom or the hydroxyl or
amino-group is not due to the influence of these per se, but depends
on whether they increase or diminish the difference in the positive and
negative characters of the components of the coloured substance.

When chlorine is passed into a solution of di-iododiphenyl in
chloroform, yellow crystals of the dichloride, C₁₂H₈I₂Cl₂, m. p. 146°
(decomp.), are obtained. By heating the dichloride with benzidine in
chloroform or carbon disulphide, a substance, C₂ₙH₂ₙN₂Cl₂I₂, is
obtained in the form of a violet-blue powder, which sublimes and
decomposes at 300°.

Equal molecular quantities of quinone and benzidine in chloroform
yield a mass of bluish-violet needles with a red, metallic lustre, which
melt indefinitely at 118°, resolidify, and decompose above 200°.

The reaction between methyl glutarate and excess of magnesium
phenyl bromide in ether leads to the formation of the ketone,
\[ \text{CPh}_2 \cdot \text{CH} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{COPh} \]
m. p. 176°, which forms colourless crystals, and develops a bluish-green
coloration with concentrated sulphuric acid. If the Grignard reagent
is not in excess, the product of the reaction is the ester,
\[ \text{CPh}_2 \cdot \text{CH} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CO}_2 \text{Me} \]
m. p. 120°.

C. S.

Rate of Decay of the Excited Radioactivity from the
New South Wales, 1906, 40 158—160).—A copper wire, 10 metres
long, kept negatively charged at a potential of 25,000 volts, was after three hours' exposure rubbed with cotton wool moistened with ammonia. The cotton wool was incinerated, and the ashes tested for radioactivity; the time taken for the activity to fall to half value was on four days in December, 1905, found to be 41·5, 40·7, 41·9, and 39·5 minutes.

P. H.

Radioactivity of the Rocks in the Region Traversed by the Line to the Simplon. Gino Gallo (Atti R. Accad. Lincei, 1908, [v], 17, ii, 209—214).—The author has examined the radioactivity of various rocks excavated in the laying of the railway line to the Simplon. The limestone-gypsums and the rocks of the calcareous schist zone are either quite inactive or very feebly radioactive. With the orthogneisses, however, the chemical composition and coefficient of acidity of which indicate that they belong to the eruptive granitic magmas, moderately intense radioactivity is observed, the maximum value found being 43·2 volt-hours. The radioactivity is, in general, accompanied by the presence of certain minerals, such as titanite and zirconia. The pyrites minerals are also moderately radioactive, but the radioactivity cannot be definitely attributed to the metallic sulphides, and not to the gneissic gangue accompanying them. Borne (Jahrb. Radioaktiv. Elektronik., 1905) has shown that, of the springs issuing from these rocks, those which are richest in emanation have their origin in the gneiss or in the granitic rocks.

T. H. P.

Preliminary Observations on Radioactivity and the Occurrence of Radium in Australian Minerals. D. Mawson and T. H. Laby (J. Roy. Soc., New South Wales, 1905, 38, 382—389).—A number of Australian minerals were examined for radioactivity by the ionisation produced in an air gap, the activity being compared with that of black oxide of uranium. Radium was tested for, and found in the case of two Australian minerals, but a gadolinite known to contain helium gave no radium emanation.

P. H.

Preparation of Radium from Pitchblende. Heinrich Paweck (Zeitsch. Elektrochem., 1908, 14, 619—623).—A description of the process of manufacture of radium salts used at the radium works of the Austrian Government at St. Joachimsthal. The ores of Joachimsthal have been worked since 1518, first for silver, then for cobalt, nickel, arsenic, and bismuth, and more recently for uranium. In 1907 the extraction of radium from the residues from the uranium ore was begun. The raw ore is ground and washed to remove the lighter rock constituents, it is then roasted at 800° to remove sulphur, and finally heated again with sodium carbonate. Uranium, arsenic, antimony, tungsten, molybdenum, and vanadium are washed out in the form of sodium salts. From the residue, iron, aluminium, calcium, silicon, and lead are removed by boiling with sodium hydroxide and then with hydrochloric acid, very thorough washing following each operation. The residue contains barium and radium sulphates, which are converted into carbonates by repeated treatment with sodium carbonate and thorough washing, and then dissolved in hydrochloric
acid and reprecipitated by sulphuric acid. This treatment is repeated several times. The solution of the chlorides is finally evaporated to dryness, and extracted with concentrated hydrochloric acid, which leaves a residue consisting mainly of barium and radium chlorides, which is submitted to fractional crystallisation. Of the radioactivity of the original ore, 73·9% is found in the residue from the uranium extraction, and the remainder in the solid uranium salts produced; there is no loss in waste products.

T. E.

Quantitative Estimation of Radium Emanation in the Atmosphere. George C. Ashman (Amer. J. Sci., 1908, [iv], 26, 119—120).—The author has determined the radioactivity of 200 litres of Chicago air taken from the ground level. The purified air was passed through a long copper spiral immersed in liquid air to condense the emanation, which was afterwards volatilised into an electroscope and estimated. Precisely the same results were obtained in simultaneous estimations by this method, which is considered to be the best hitherto devised for the purpose.

The radium equivalent of the emanation per cubic metre of air was found to be 86, 58, and $45 \times 10^{-12}$ gram in three experiments. Immediately after a thaw and heavy rain, the amount rose to $200 \times 10^{-12}$ gram; under normal weather conditions with high barometer, the value $51 \times 10^{-12}$ was found, whilst with a low barometer the amount was $131 \times 10^{-12}$.

The mean value, the equivalent of $1·0 \times 10^{-10}$ gram of radium per cubic metre is 25% higher than the amount given by Eve. If the emanation has an appreciable vapour pressure at the temperature of liquid air, even the present estimate must be somewhat too low.

The active material had a half-period of decay of 3·5 days, indicating that it consisted only of radium emanation and that thorium emanation was absent.

R. J. C.

Amount of Radium Emanation in the Atmosphere. John Satterly (Phil. Mag., 1908, [vi], 16, 584—615).—The amount of radium emanation present in the atmosphere of Cambridge has been measured by two methods. In the first, the emanation in a known volume of air was absorbed by charcoal; in the second, it was condensed by means of liquid air. The electrical conductivity imparted to a given volume of air by the absorbed or condensed emanation was then compared with the conducting power brought about by the emanation emitted from a definite volume of a radium solution of known strength. The results of the two methods of measurement, which agree fairly well, show that the amount of radium emanation in the atmosphere varies very considerably. On the average, the quantity contained in a cubic metre of air is equal to the amount which would be in radioactive equilibrium with about $1 \times 10^{-10}$ gram of radium. No connexion between the variation in the concentration of the emanation and the meteorological conditions could be detected. The observed values indicate that only a small proportion of the natural ionisation of the air is due to the presence of the radium emanation and its products.

H. M. D.
Amount of Radium Emanation in the Atmosphere near the Earth's Surface. A. S. Eve (Phil. Mag., 1908, [vi], 16, 622—632. Compare this vol., ii, 7).—Experiments according to the method already described have been continued at intervals for almost a year. An error in the previous calculations is pointed out, and this is corrected in the evaluation of the new experimental data.

The average amount of emanation present in a cubic metre of the air of Montreal during the period of the experiments is that which would be in equilibrium with $60 \times 10^{-12}$ gram of radium. The observed variation in the concentration of the emanation is such that the maximum is to the minimum as 7 is to 1. Changes of temperature have little or no influence on the concentration of the emanation, but it increases on the approach of a deep cyclone accompanied by heavy rain or a thaw of snow, and decreases with anticyclonic conditions when the weather is dry or very cold. H. M. D.

The Heat Developed by Radium. Egon von Schweidler and V. F. Hess (Monatsh., 1908, 29, 853—862).—A quantity of over 1 gram of radium chloride was used for the experiments. A differential calorimeter was used consisting of two gilt-copper vessels in a chamber at constant temperature. One vessel contained the radium, and the other was heated by means of an electric current. Two copper-nickel thermo-junctions were balanced against one another, the heating current being adjusted until the temperatures were equal.

The results indicate a heat development of 118.0 cal. per hour for 1 gram of metallic radium, with a possible error of 1.4%. This is in good agreement with the value, 117 cal., obtained by Ångström (Abstr., 1906, ii, 63).

Relation between Uranium and Radium. III. Frederick Soddy (Phil. Mag., 1908, [vi], 16, 632—638).—A further examination of the carefully-purified uranium salts prepared in 1905-06 has been made to ascertain the rate of production of radium (compare Soddy and Mackenzie, Abstr., 1907, ii, 730). In one case, the growth of radium is not greater than $5 \times 10^{-11}$ gram per kilo. of uranium in $2\frac{3}{4}$ years, and in the other, it is not greater than $1 \times 10^{-11}$ per gram kilo. of uranium in $1\frac{3}{4}$ years.

An examination of the residues from the highly-purified uranium salts has shown that the amount of radium present has increased about seven times during a period of one year. This indicates that a radium-producing substance is present in commercial uranium salts. Further, since the residues had been purified by the barium sulphate method with the object of removing radium and any intermediate products in the transformation of uranium into radium, it is established that the barium sulphate purification process does not remove the whole of this radium-producing substance. H. M. D.

Radiation of Uranium X. Max Levin (Physikal. Zeitsch., 1908, 9, 655—657. Compare Abstr., 1907, ii, 836).—As the distance between the radiating substance and the ionisation chamber is diminished, the ionisation produced by uranium $X$ slowly increases at
first, attains a maximum value, and then rapidly diminishes. If the active substance is covered with a thin layer of aluminium, there is no evidence of this maximum ionisation value. The following explanation of the observed maximum in the case of the uncovered substance is given. As the distance between the source and the ionisation chamber increases, the actual number of ions which are discharged increases. When this distance is considerable, the strength of the electric field is not sufficient to bring about the discharge of all the ions before reunion takes place. If the ionisation per centimetre were constant, this should lead to a constant limiting ionisation when the distance is sufficiently great, but the fact that the strongly ionised layer in the immediate neighbourhood of the active substance is gradually removed from the measuring chamber influences the ionisation in such a way that, although an increase takes place at first with increasing separation, this is more than compensated for by the second effect when the distance has attained a certain value.

H. M. D.

**Actinium C, a New Short-lived Product of Actinium.** Otto Hahn and Lise Meitner (Physikal. Zeitsch., 1908, 9, 649–655).—Measurements of the ionisation produced by the α- and β-radiation emitted by the induced activity of actinium indicate that this consists of three disintegration products: actinium A, B, and C. Actinium C was separated from A by the action of finely-divided metals and animal charcoal on a solution of the active deposit, and its period of decay was found to be 5·10 minutes. It emits no α-rays, but the β-rays previously attributed to actinium B are found to be due to actinium C. The α-rays given off by the active deposit are entirely due to actinium B, whilst actinium A only emits a very readily absorbed type of β-radiation. In agreement with Bronson's determination, the decay period of actinium B is found to be 2·15 minutes, and that of actinium A, thirty-six minutes. These two products can be separated by heating the active deposit for about thirty seconds in a blow-pipe flame; the separation is not, however, complete even when the temperature is raised to 2000°.

Equations are given which represent the change in the α- and β-activity of the active deposit in agreement with the experimental observations.

H. M. D.

**Range of Activity and Absorption of α-Rays. Secondary Radiation Produced by α-Rays.** E. Aschenkass (Ann. Physik, 1908, [iv], 27, 377–390).—An apparatus is described by means of which the charge on α-particles from polonium could be measured after passing through aluminium foil in a high vacuum. A magnetic field was employed to remove electrons and secondary radiation.

As found by other workers, layers of aluminium foil up to 13·7μ in thickness allow the whole of the α-particles to pass. At about 24μ, the particles are completely arrested. It is probable that complete absorption occurs suddenly at a definite thickness of aluminium.

Experiments with the same apparatus in the absence of a magnetic field indicate that the negative radiation from polonium considerably exceeds the positive in quantity. The secondary radiation produced by the α-particles may also be studied by its means.

C. H. D.
Ionisation of Gases by α-Rays, and the Hypothesis of Initial Recombination of the Ions. M. Moulin (Chem. Zentr., 1908, ii, 474—475; from Le Radium, 1908, 5, 136—141. Compare Abstr., 1906, ii, 720).—The hypotheses of Bragg and Kleeman, and Langevin, as explanatory of the unsaturation of an electric current at low E.M.F. when passed through a gas ionised by α-rays, have been tested by the author. The evidence so far obtained appears to support Langevin’s view, that the α-rays produce a larger number of ions, which, however, become arranged along the path of the α-rays.

J. V. E.

Quality of the Secondary Ionisation due to β-Rays. William H. Bragg and J. P. V. Madsen (Phil. Mag., 1908, [vi], 16, 692—697).

—Experiments are described which show that the secondary rays reflected by different substances struck by the same bundle of primary rays are not uniform in quality, but vary from one substance to another. For the purpose of collecting all the secondary rays, the authors have made use of an ionisation chamber with a hemispherical wall.

It is found that the secondary rays returned by substances of low atomic weight contain a relatively large proportion of less penetrating rays. When the less penetrating portions of the primary beam are cut off, the emitted secondary rays are found to be more penetrating. On account of these facts, observations of secondary radiation cannot be accurately made when ionisation vessels of the ordinary type are employed.

H. M. D.

Attempts to Detect the Production of Helium from the Primary Radio-elements. Frederick Soddy (Phil. Mag., 1908, [vi], 16, 513—530).—Experiments have been made to obtain a quantitative estimate of the amount of helium produced from uranium and thorium. By the process recently described (Abstr., 1907, ii, 251), it is possible to detect $2 \times 10^{-10}$ gram of helium by observation of the $D_3$ line. In an experiment in which 350 grams of thorium in the form of nitrate were employed, helium to the extent of about $2 \times 10^{-10}$ gram was detected after a period of accumulation of nearly seven months. This corresponds with a rate of production of $2 \times 10^{-12}$ per year. The two estimated rates of production, on the assumption that the helium atom is identical with an $α$-particle, are, according to two different methods, $2 \times 10^{-12}$ and $4.5 \times 10^{-12}$. It may be pointed out that the former value is almost eight times less than the value calculated three years ago.

H. M. D.

Rate of Production of Helium from Radium. Sir James Dewar (Proc. Roy. Soc., 1908, 81, A, 280—286).—The rate of production of helium from radium was determined directly by observing the growth of pressure in a McLeod gauge connected with a vessel containing 70 mg. of radium chloride. A small tube containing coconut charcoal was sealed on to the gauge; the tube was kept in liquid air during an experiment, and served to condense any gases, other than helium or hydrogen, which might be generated in, or leak
ABSTRACTS

G. S.

into, the apparatus. Before starting an experiment, the apparatus was exhausted, first with a mercury pump, then with a large bulb containing charcoal immersed in liquid air, which was sealed off after some hours, and, finally, to a pressure of 0·00005 mm. by cooling the small charcoal bulb.

The second and more satisfactory experiment lasted 1100 hours. At intervals, the radium was heated to low redness, causing an increase of pressure after cooling to room temperature, which remained steady, showing that part of the helium had been occluded by the radium. Direct experiment showed that the helium was not appreciably occluded by the charcoal. It was further shown by examination of the spectrum, and by two other independent methods, that the helium was not contaminated with hydrogen.

A mean line drawn through the observations with the radium heated, shows a steadily maintained helium increment of approximately 0·37 c.mm. per gram of radium per day, a result which agrees almost exactly with that calculated by Rutherford on the assumption that the α-particle is an atom of helium carrying two ionic charges. On the other hand, Ramsay and Cameron (Trans., 1907, 91, 1274) have determined the rate of production of the emanation from radium, the ratio of the amount of helium to that of the emanation being found by them to be 3·18; their value is about eight times as great as that of the author. It is pointed out in a footnote that Rutherford's experimental determination of the rate of production of the emanation gives a value about one-tenth that obtained by Ramsay, but in good agreement with the present results, on the assumption that the ratio of helium to emanation is 3 : 1.

Accumulation of Helium in Geological Time. ROBERT J. STRUTT (Proc. Roy. Soc., 1908, 81, A, 272—277).—The experiments were undertaken in order to obtain a comparison of the helium content of minerals with their geological age. It was found that phosphatic nodules and phosphatised bones, occurring in such strata that their relative age was well defined, possessed a radioactivity much higher than that of rocks, and that the activity was connected with the presence of uranium minerals.

The helium was liberated by dissolving the minerals in acids, and separated from other gases by special methods. The radium content of the minerals was determined in the usual way, and from the results the percentage of uranium oxide calculated by comparison with a standard uranium mineral.

The ratio of helium to uranium oxide is not strictly proportional to the age of the strata, but high ratios are not found in the younger strata, whereas they are common in the older ones. The absence of direct proportionality is ascribed to imperfect retention of the helium.

From the results, on the basis of Rutherford's estimate of the rate of production of helium from radium, an attempt is made to calculate the age of the strata. The following are provisional minimum values:

Phosphatic nodules of the crag, 225,000 years; of the upper green-
sand, 3,080,000 years; of the lower greensand, 3,950,000 years; and hematite overlying carboniferous limestone, 141,000,000 years.

G. S.

Helium in Saline Minerals, and its probable Connexion with Potassium. ROBERT J. STRUTT (Proc. Roy. Soc., 1908, A, 278—279).—The ratio of helium to uranium oxide has been determined (as described in the previous abstract) for the Stassfurt minerals, sylvine, carnallite, kieserite, and rock salt, and a number of other minerals from the same source have been examined qualitatively. Only for sylvine and carnallite is the ratio so high that it cannot be accounted for by the uranium present, and it is suggested that potassium may be the source of the helium in these two minerals (compare Campbell and Wood, Abstr., 1907, ii, 217; McLennan and Kennedy, this vol., ii, 750).

G. S.

Electrical Conductivity of Alloys and their Temperature-coefficients. ERNST RUDOLFI (Physikal. Zeitsch., 1908, 9, 607—609).—Polemical against Guertler (compare this vol., ii, 557).

H. M. D.

Conductivity of Fused Salts. KURT ARNDT and ALBERT GESSLER (Zeitsch. Elektrochem., 1908, 14, 662—665).—The conductivities of a number of salts are measured by the method described by Arndt (Abstr., 1906, ii, 418). The results (in reciprocal ohms per cm.) are:

The conductivity is in all cases a linear function of the temperature; for the alkali salts it is approximately proportional to the absolute temperature. The conductivities of mixtures of potassium and sodium chlorides and of calcium and strontium chlorides are very nearly the mean of those of the constituents.

The equivalent conductivities are calculated by means of the figures in the preceding abstract.

T. E.

Limiting Conductivity of Some Electrolytes in Ethyl Alcohol. Paul Dutoit and H. Rappeport (J. Chim. Phys., 1908, 6, 545—551).—The alcohol used in the measurements had a specific conductivity of the order 10⁻⁷ reciprocal ohms. The values of the limiting molecular conductivity, \( \mu_\infty \), were obtained directly by measurements in very dilute solution (up to a dilution of 20,000 litres) and indirectly by extrapolation from measurements in more concentrated solutions. The values of \( \mu_\infty \) at 18°, expressed in Siemens units, are 39·2, 39·1, 35·8, and 35·0 respectively for the iodides of potassium, sodium, lithium, and ammonium, and 41·1 and 38·0 for the thiocyanates of potassium and ammonium respectively. Ammonium bromide gives 36·4, and sodium acetate, 31·8.

Kohlrausch's law holds for the electrolytes examined within the limits of experimental error, but the dilution law does not apply.

The order of the speed of the ions is the same in water and in alcohol, but the ratio of the speeds in the two solvents is by no means constant, varying from 1·8—3·1.

G. S.

A Light Accumulator. R. Goldschmidt (Bull. Soc. chim. Belg., 1908, 22, 317—327).—An accumulator in which the electrodes are zinc and oxide of nickel, and the electrolyte a concentrated solution of potassium carbonate, is described. The changes taking place on charging and discharging are represented by the upper and lower arrows respectively in the equation \( \text{Ni}_2\text{O}_3 + 2\text{Zn} \rightleftharpoons \text{NiO} + 2\text{ZnO} \), the electrolyte taking no direct part in the reaction. The nickel peroxide electrodes are prepared by electrolysis of a solution of nickel silico-fluoride containing a little cobalt silico-fluoride, nickel plates being used as anode, and the nickel deposited on a sheet of iron covered with nickel serving as cathode. A constant \( E.M.F. \) of about 2·75 volts is employed. After seven to eight hours' electrolysis, it is necessary to add a little cobalt silico-fluoride and free hydrofluosilicic acid to the electrolyte to prevent the formation of a green mass on the cathode. The plate thus prepared is washed and oxidised electrolytically in a solution of sodium carbonate.

The zinc electrodes are prepared by electrolysis of a strong solution
of zinc silicofluoride containing a little free acid, zinc plates being used as anode, and the zinc deposited on iron as cathode. It is remarkable that much better deposits of zinc are obtained after the electrolyte has been in use for some time.

The plates thus prepared are immersed in a 43% solution of potassium carbonate or a 25% solution of sodium carbonate to form an accumulator; the potassium salt is preferable. An accumulator of this type has a capacity of at least 60 ampere-hours per kilo. of positive electrode; with a current of 15—20 amperes, the yield is about 100 watts, and the mean E.M.F., 1.57 volts. It has the further advantage that it can be charged with a very large current, up to 50 amperes per kilo. of positive electrode, without damage.

G. S.

Formation of Gas in Discharge Tubes. Rudolf von Hirsch (Physikal. Zeitsch., 1908, 9, 603—606. Compare Hirsch and Soddy, this vol., ii, 12).—The author has investigated the gas which is evolved from aluminium electrodes containing sodium as an impurity when cathode rays are generated by means of an influence machine. About 50% of the gas is absorbed by glowing copper oxide, and consists of hydrogen. The remainder appears to be carbon dioxide, for the spectral bands of this gas become much stronger after the removal of the hydrogen. This mixture of gases differs from others previously examined in that the product \( p^2V \) is constant, \( p \) being the gas pressure and \( V \) the discharge potential. It has been suggested previously (loc. cit.) that the constancy of \( p^2V \) is characteristic of pure gases, and this has led to a detailed examination of mixtures of hydrogen and carbon dioxide.

The value of \( p^2V \) for pure carbon dioxide is about 1/22 of that for hydrogen; the connexion between the value of the product and the molecular weight of the gas does not hold therefore in this case. For mixtures of the two gases, \( p^2V \) is not constant; the curve, which represents the deviations of the product from a constant value, exhibits maxima for mixtures containing a large excess of one or the other gas, and a minimum for which \( p^2V = 4 \).

Analysis of two mixtures giving this minimum value showed that approximately equal quantities of the two gases are present. This mixture is the one produced from the aluminium electrodes, the constancy of the proportions between the two gases being maintained automatically. The formation of the gases is due to the action of water and carbon dioxide on the sodium contained in the aluminium.

H. M. D.

Chemical or Physical Theory of Volatilisation (of Cathodes). Franz Fischer and Otto Hähnel (Zeitsch. Elektrochem., 1908, 14, 677—681). Volkmar Kohlschütter (ibid., 681—683).—Fischer and Hähnel regard the volatilisation as a purely physical phenomenon; Kohlschütter upholds his chemical hypothesis (this vol., ii, 457, 653, 799, and 800).

T. E.

Volatilisation of Cathodes in Attenuated Gases. B. Walter (Zeitsch. Elektrochem., 1908, 14, 695).—In Fischer and Hähnel's experiments (this vol., ii, 653), the current passing in the argon vol. xciv. ii.
and hydrogen tubes is the same, but the energy consumed is greater in hydrogen; hence for equal quantities of energy the volatilisation would be greater in argon.

T. E.

Behaviour of Calcium and Sodium Amalgams as Electrodes in Solutions of Neutral Salts. Horace G. Byers (J. Amer. Chem. Soc., 1908, 30, 1584—1586).—Le Blanc and Novotny (Abstr., 1907, ii, 22) found that the values of the equilibrium constant of the reaction between sodium carbonate and calcium hydroxide, obtained by direct determination, did not agree with those calculated from the solubilities of calcium hydroxide and calcium carbonate. An attempt has therefore been made to determine this constant by measuring the E.M.F. of the cell CaHg—CaCO₃—Na₂CO₃ | NaOH—Ca(OH)₂—CaHg, K being calculated from the equation \[ \pi = RT/7 \times \ln K/a. \] The value of \( \pi \), however, could not be satisfactorily determined, owing to the rapid action of water on the calcium amalgam, but interesting results were obtained on the action of solutions of salts on the amalgam. Similar experiments were made with sodium amalgam and solutions of salts. The results are tabulated.

It has been found that when amalgams are treated with solutions of salts of alkali or alkaline-earth metals, replacement occurs, and the determination becomes that of the E.M.F. of an electrode consisting partly of the amalgam of the metal of the added solution. Replace-

ments of this character in concentrated amalgams have been recorded previously.

E. G.

Anomaly of the Strong Univalent Electrolytes M. Kata-

yama (J. Coll. Sci. Tokyö, 1908, 25, vii, 1—42).—By combining the views of Nernst (Abstr., 1901, ii, 647) and Jahn (Abstr., 1900, ii, 522; 1901, ii, 491; 1902, ii, 597) with those of Storch (Abstr., 1896, ii, 288) and Bancroft (Abstr., 1900, ii, 186), the author has deduced the following empirical formula:

\[ K = \frac{c_i}{c_n} \left( \frac{c_i}{c_n} \right)^{0.3} c_n, \]

that is, \( \log K = n \log \lambda \frac{\lambda}{\lambda_{\infty}} - \log \lambda_{\infty} - \lambda \frac{\lambda}{\lambda_{\infty}} - 0.3 \frac{\lambda^2}{(\lambda_{\infty} - \lambda)_{\lambda_{\infty}}} \log \frac{\lambda}{\lambda_{\infty} - \lambda}. \]

where \( K \) is a constant, \( c_i \) the concentration of the ions in gram-mols per litre, \( c_n \) the concentration of the neutral, undissociated molecules; \( c_i + c_n = c \) the total concentration, \( n \) a constant, \( \lambda \) the equivalent conductivit

ity for the concentration \( c \), and \( \lambda_{\infty} \) the equivalent conductivity for infinite dilution. The values obtained with this formula are in close agreement with the observed conductivities for every kind of univalent electrolyte.

In conjunction with Nernst's theory of solutions (loc. cit.), the following assumptions were made: \( \pi_1 = a_1 c_n c_i \); \( \pi_2 = a_2 c_i \left( \frac{c_i}{c_n} \right)^{0.3} c_n \); where \( \pi_1 \) is the vapour pressure of the neutral molecule, \( \pi_2 \) the vapour pressure of the cation or anion, and \( a_1, a_2, \) and \( s \) are constants. The
values for the \textit{E.M.F.} calculated on the second assumption are in fair agreement with the observed values. The partition-coefficient values obtained by Rothmund and Drucker for picric acid (Abstr., 1904, ii, 231) are well explained with the aid of the first assumption. By combining the two, it is possible to calculate the lowering of the freezing point of an aqueous solution of a strong electrolyte, which as a rule is in agreement with the observed depression.

W. H. G.

The Size of Molecules and Charge of the Electron. \textsc{Jean Perrin} (\textit{Compt. rend.,} 1908, \textit{147}, 594—596).—The number \((N)\) of molecules in a gram-molecule, the charge \((e)\) of the electron, and the ratio \((a)\) of the mean energy of a molecule to its absolute temperature are universal constants, all of which are known when the value of one is determined, since (1) in the electrolysis of a univalent salt 96550 coulombs are conveyed by \(N\) atoms, whence \(Ne = 3 \times 10^9 \times 96550\) electrostatic units; (2) the kinetic energy of a gram-molecule is measured by \(3RT\), so that \(2Na = 3R = 3 \times 83.2 \times 10^5\).

The values \(3 \times 10^{-10}\) (Townsend), \(3.4 \times 10^{-10}\) (J. J. Thomson), \(6.8 \times 10^{-10}\) (J. J. Thomson), and \(3.1 \times 10^{-10}\) (H. A. Wilson) have been found for \(e\), and from them values varying from \(43 \times 10^{22}\) to \(96 \times 10^{22}\) derived for \(N\). Planck has obtained the value \(2.02 \times 10^{-16}\) for \(a\) and deduced \(61 \times 10^{22}\) for \(N\), but Lorentz from the same data finds \(N = 77 \times 10^{22}\). The author has determined \(N\) by a method based on the assumption that equal particles distribute themselves in a dilute emulsion in the same manner as molecules of the same mass which obey the gas laws. This leads to the equation \(2.3 \log_{10} n_0 / n = NRT / (4/3a^2g(d - \sigma)k)\), in which \(n\) and \(n_0\) signify the concentrations of the particles at levels separated by the distance \(h\), \(a\) the radius of the particles, and \((d - \sigma)\) the excess of their density over that of water. After finding that particles of very different size gave the same value for \(N\), the value \(71 \times 10^{-22}\) was obtained, and the values \(4.1 \times 10^{-10}\) and \(1.7 \times 10^{-16}\) thereby deduced for \(e\) and \(a\) respectively.

From this value of \(N\), the mass of the oxygen molecule is \(0.45 \times 10^{-22}\) gram, of the hydrogen atom \(1.40 \times 10^{-24}\) gram, and of the corpuscle \(0.75 \times 10^{-27}\) gram.

Magnetic Susceptibility of Solutions. \textsc{P. Pascal} (\textit{Compt. rend.,} 1908, \textit{147}, 242—244. Compare this vol., \textit{vi}, 756).—The rule that a magnetic atom becomes more diamagnetic the more it enters into complex ions or colloidal molecules, and becomes removed from its characteristic chemical properties, has been verified in the cases of certain ferrous, cobalt, chromium, copper, and mercury salts. Ferro-pyrophosphates, ferro-oxalates, and ferrometaphosphates are oxidised at rates which are in order of their magnetism. The decrease of magnetism on adding sodium carbonate to these salts is accompanied by a slower rate of oxidation.

R. J. C.

Relation of Melting Point to the Surface of the Granules of a Solid Substance. \textsc{P. N. Pawloff} (\textit{J. Russ. Phys. Chem. Soc.,} 1908, \textit{40}, 1022—1066).—From theoretical considerations, the author shows that the relation between the melting point, \(T\), of a substance and the
radius, \( r \), of its granules is expressed by the following differential equation:

\[
dT/dr = \left[ A(v_2 - v_1) p_2 k/r^2 dR\sigma \right] / \left[ \rho + A(v_2 - v_1) p_2 k/r. dR\sigma T \right],
\]

where \( A \) is a constant independent of the magnitude of the granules for any given temperature, and is given by the expression: \( \log Ap = 2k/rdR\sigma T \); \( k \) is the surface tension at the separation of the solid from vapour; \( r \) the radius of the spherical granules; \( \sigma \) the specific volume of the vapour; \( \rho \) the specific heat of liquefaction; \( v_2 \) and \( v_1 \), the volumes of unit masses of the liquid and solid respectively at the melting point.

Granules of commercial salol having a magnitude of 8\( \mu \) melt 3.5° lower than those 32\( \mu \) in size. After one recrystallisation, granules of 6\( \mu \)–40\( \mu \) melt within an interval of 1.5°. Dust having dimensions less than 2\( \mu \) melts, in the case of salol 7°, with antipyrine 5–7°, and with phenacetin 4°, lower than large granules of diameter 0.5–2 mm.

T. H. P.

**Apparatus for Determining the Freezing Point of Mixtures.**

Otto Scheuer (*J. Chim. Phys.*, 1908, 6, 620–624).—Two forms of apparatus suitable for determining the freezing point of mixtures are described. The first is a modified Beckmann apparatus. The essential feature of the second is that the stirring is concentric, and is effected by means of the thermometer, to the lower part of which two strips are attached for this purpose.

G. S.

**Negative Adsorption.**

Reginald O. Herzog (*Zeitsch. physiol. Chem.*, 1908, 57, 315–316).—Tezner and Roske state (this vol., ii, 810) that negative adsorption does not occur. This, however, is only true when the adsorption of a single substance is dealt with, and instances are given where, under other conditions, the phenomenon does take place.

W. D. H.

**The Fusion Curves of the System Naphthalene–Phenol.**

T. Yamamoto (*J. Coll. Sci. Tokyô*, 1908, 25, xi, 1–23).—The freezing-point curve of mixtures of naphthalene and phenol was determined by the cryoscopic method, a correction being made for supercooling. The eutectic point lies at 29.7° and 15.7 mol. % naphthalene. The form of the phenol curve is explained as being due to the association of phenol in the liquid state, represented by the equilibrium \( 3C_6H_6O = (C_6H_6O)_3 \). The equilibrium constant of this association is expressed as a function of temperature, the heat of association being also determined.

C. H. D.

**The Fusion Surfaces of the System Naphthalene–Chlorobenzene–Phenol, and the Molecular Association of Phenol.**

H. Hirobe (*J. Coll. Sci. Tokyô*, 1908, 25, xii, 1–50. Compare preceding abstract).—The fusion surfaces (freezing-point surfaces) of naphthalene and phenol in the ternary system have been determined, an accurate cryoscopic method being employed. The two surfaces are separated by a eutectic curve, the projection of which on the plane of composition is nearly a straight line. The form of the surfaces is
consistent with the assumption that naphthalene and chlorobenzene are non-associated, and that phenol is partly associated to triple molecules. The latter conclusion was supported by determinations of the partition-coefficient of phenol between chlorobenzene and an aqueous solution of sodium chloride and sodium sulphate. C. H. D.

Arrangement for Liquefying and Distilling Easily Condensible Gases and Low-boiling Liquids. Aurel von Bartal (Chem. Zeit., 1908, 32, 891).—A U-shaped form of receiver which can be completely immersed in a freezing mixture contained in a vessel consisting of two concentric cylinders between which there is a layer of asbestos; in this way, a very effective condensation is ensured. When removed from the freezing mixture, the apparatus can be employed as a distillation flask by gently warming it; the distillate may be condensed in a second similar apparatus cooled in a freezing mixture.

Practical Studies in Vacuum Sublimation. Richard Kempf (J. pr. Chem., 1908, [ii], 78, 201—259).—The employment of sublimation in a vacuum as a means of purification entails a smaller loss of substance than does recrystallisation, whilst, on the other hand, in consequence of the slower volatilisation, a more complete separation of a mixture is secured than by fractional distillation. The author describes an arrangement for sublimation experiments suitable for use in a laboratory, consisting of a glass tube on to one end of which is ground a glass cap with a tap and nozzle for connecting with the pump, and on to the other a bent pear-shaped glass bulb. This bulb, containing the substance to be sublimed, is heated in a suitable air-oven; the straight tube projecting through a hole in the side of the oven serves as the receiver for the sublimate. The phenomena of sublimation are discussed, and details given of experiments with fifty-three inorganic and organic compounds.

Heat of Combination of Acidic Oxides with Sodium Oxide and Heat of Oxidation of Chromium. William G. Mixter (Amer. J. Sci., 1908, [iv], 28, 125—137. Compare Abstr., 1907, ii, 738).—The heats of formation of sodium orthoborate, aluminate, chromate, and tungstate have been determined by firing mixtures of sodium peroxide with the metals or with metallic oxides in presence of carbon. Incidentally, the heats of formation of chromium sesqui-oxide and trioxide were calculated. Since the salts in question are largely hydrolysed by water, previous determinations by Thomsen, Berthelot, and others which referred to solutions are regarded as less trustworthy than those obtained by the sodium peroxide method. The heat of formation of sodium sulphate, on the other hand, is found to be the same by both methods. The principal results obtained were:

\[
\begin{align*}
3\text{Na}_2\text{O} + \text{B}_2\text{O}_3 &= 2\text{Na}_3\text{BO}_3 \\
\text{Na}_2\text{O} + \text{Al}_2\text{O}_3 \text{(amorphous)} &= 2\text{NaAlO}_2 + 40,000 \\
\text{Na}_2\text{O} + \text{Cr}_2\text{O}_3 &= \text{Na}_2\text{CrO}_4 + 77,000 \\
\text{Na}_2\text{O} + \text{WO}_3 &= \text{Na}_2\text{WO}_4 + 94,700 \\
\text{Cr} + 3\text{O} &= \text{Cr}_2\text{O}_3 + 140,000 \\
2\text{Cr} + 3\text{O} &= \text{Cr}_2\text{O}_3 \text{(amorphous)} + 243,800
\end{align*}
\]
The heats of transformation of aluminium and chromium oxides from the amorphous to the crystalline state were also determined.

During the combustions which were made in a silver bomb, or a silver cup suspended in a steel bomb, a small amount of oxygen was always liberated, for which a correction was necessary.  

R. J. C.

Viscosity of Certain Metals and its Variation with Temperature.  

Charles E. Guye and S. Mintz (Arch. sci. phys. nat., 1908, 26, 136—166, 263—278).—From observations on the rate of decrease of the amplitude of vibration of loaded wires when twisted, the authors have compared the viscosity of platinum, silver, gold, copper, and steel at different temperatures. To eliminate the damping effect of the air, the vibrating wire was enclosed in an apparatus which could be exhausted.

The viscosity increases with the temperature in the case of platinum, silver, gold, and copper, and the curves which express the relationship between the two factors are of the same type. In the case of steel, the viscosity increases up to about 100°, then falls, and passes through a minimum value at about 200°, above which it increases very rapidly. This phenomenon can be observed both with rising and falling temperatures, indicating that it is due to reversible changes.

The influence of temperature on the viscosity is diminished by previous annealing; it increases when the load on the wire is increased.

H. M. D.

Viscosity of Dilute Alcoholic Solutions.  

Toshio Hirata (J. Coll. Sci. Tôkyô, 1908, 25, v, 1—15).—Arrhenius has shown (Abstr., 1880, 336) that the viscosity of an aqueous solution of any two indifferent substances may be expressed by the formula \( z = A^x B^y \), where \( A \) and \( B \) are two constants characteristic of the two solutes at a constant temperature, \( x \) and \( y \) being their respective volume percentages. With the object of ascertaining whether ethyl-alcoholic solutions follow the same law, the viscosities of ethyl-alcoholic solutions of various liquids, chiefly organic, have been measured. It is found that the formula can be applied to the solutions of all the substances examined, the error being less than 1% for solutions containing less than 10% by volume of the dissolved substance. Water, however, forms an exception; in this case, the formula can be applied only to very dilute solutions. When the concentration exceeds 3% by volume, the error is greater than 1%.

W. H. G.

Viscosity and Ionic Volume.  

Frederick H. Getman (J. Chem. Phys., 1908, 6, 577—583. Compare this vol., ii, 464).—Jones and Veazey (Abstr., 1907, ii, 438) have pointed out that the salts which diminish the viscosity of water have a large ionic volume, and there is evidence that for salts with the same anion the diminution of viscosity of the solvent is proportional to the atomic volume of the cation. In the present paper, this relationship is further illustrated by application to a number of nitrates and chlorides.

In order to show the relationship more clearly, the viscosity of solutions of the same salts is compared, when the degree of dissocia-
tion in each case is 75%. Under these circumstances, the viscosity, $\eta$, is represented by the formula:

$$10^4 \times \eta = 89 \pm 0.0242 C_v$$

where $C_v$ is the atomic volume of the cation, and 89 represents the viscosity of water at 25°, there being good agreement between found and calculated values. On the other hand, there is no apparent connexion between the viscosity and the sum of the volumes of the ions and unionised molecules.

G. S.

Changes in Internal Friction due to Protein Degradation. Karl Schorr (Biochem. Zeitsch., 1908, 13, 173—176).—Experiments were carried out with dialysed salt-free serum, which was treated with sodium hydroxide in various dilutions. An Ostwald viscosimeter was used for the measurements.

On treatment with the alkali, there is at first an increase in the internal friction, which is followed by a steady fall. A similar phenomenon is brought about by hydrochloric acid; in the latter case, however, the fall is followed by a second rise, which is accompanied by a gradual separation of a precipitate from the liquid, which is finally sufficient to impede entirely the flow of liquid through the viscosity tube.

S. B. S.

Diffusion of Gaseous Ions. Édouard Salles (Compt. rend., 1908, 147, 627—629).—The author has measured the coefficient of diffusion of gaseous ions towards the walls of narrow metallic containing tubes. The coefficient for positive ions is 0.031, and for negative ions 0.041, the value being unaffected by interchanging tubes of German silver, brass, and steel. Contrary to J. J. Thomson’s supposition, the nature of the metal has no specific influence on the rate of diffusion of gaseous ions towards it.

R. J. C.

Osmotic Pressure of Concentrated Solutions of Non-electrolytes. Otto Sackur (Chem. Zentr., 1908, ii, 472; from Jahrb. Schweisch. Ges. Vaterl. Kultur, 1908, 86, 1—14).—According to the experiments of Morse and Frazer, aqueous sucrose solutions above 20° exert an osmotic pressure equal to the corresponding gas pressure, when the concentration is defined as the number of molecules of the dissolved substance in a volume of the solvent (Abstr., 1907, ii, 744). At lower temperatures, this agreement is not observed. If, however, the concentration is regarded as being expressed by the number of molecules of dissolved substance in a volume of the solution, the equation $p(v - b) = RT$ is applicable for all the observations with sucrose and dextrose. Contrary to the gas law, $b$, in the above equation, varies considerably with alteration of temperature; for sucrose, it decreases from 0.31 (per litre) to 0.20 when the temperature rises from 0° to 20°, and for dextrose, from 0.16 to 0.093 under a like change of temperature. The author suggests that this is due to the hydration of the dissolved substance decreasing with rise of temperature.

J. V. E.

the boiling point and molecular weight, Walker has pointed out that
the formula \( T/\sqrt{m} = 37 \) \((m = \text{molecular weight}; T = \text{boiling point on the absolute scale})\) holds more particularly for a number of hydro-
carbons, but is not generally applicable. The author now shows that
the modified expression \( T/\sqrt{m} + (1000 \sqrt{m})/T \) is about 64 for all the
normal substances examined, and varies from 65 for slightly poly-
merised substances to 99 for water.

The above equation has two roots, \( \sqrt{m_1} = T/37 \) and \( \sqrt{m_2} = T/27 \).
The ratio \( T/\sqrt{m} \) is termed \( x_1 \), and 1000 \( \sqrt{m}/T \) is termed \( x_2 \). It is only
for certain hydrocarbons and some other substances that \( x_1 = 37 \) and
\( x_2 = 27 \); for the majority of substances, \( x_1 \) is less than 37, and \( x_2 \) greater than 27. This is taken to mean that, in the liquid state, the
molecules of most substances are partly polymerised and partly dis-
sociated, the mean of the weights of the molecules being the theoretical
molecular weight, and the views of other observers are adduced in
support of this opinion.

The "factor of dissociation," \( K_1 = (x_1/37)^2 \), and the "factor of
polymerisation," \( K_2 = 1.88K_1 \), are given in tabular form for all the
liquids considered.

G. S.

Sci. Tokyö, 1908, 25, x, 1—80).—An ideal solution is defined as a
homogeneous liquid mixture, of which the volume and energy are
the sum of the volumes and energies respectively of the components
in the liquid state under the same pressure and at the same tem-
perature. An attempt is made to explain all deviations from the
properties of an ideal solution by assuming reversible chemical
reactions within the solution and applying the law of mass action.
The treatment is mathematical, and the results are applied to concrete
cases.

C. H. D.

Hardness of Solid Solutions of Metals and of Definite
Chemical Compounds. Nicolai S. Kurnakoff and S. F.
Schemtschuschny (Zeitsch. anorg. Chem., 1908, 60, 1—37 ; J. Russ.
Phys. Chem. Soc., 1908, 40, 1067—1104).—The degree of hardness
of a number of binary alloys, the structure of which is known, is
plotted against the composition, and in the majority of cases the
electrical conductivity is represented on the same diagram. The
data for the bronzes and brasses and certain other alloys are due to
previous observers, and the authors have themselves determined the
hardness of the binary alloys copper-nickel, gold-copper, and gold-
silver. It is shown that practically the same results are obtained
whether the hardness is determined by the sclerometer (ruling lines
on a prepared surface of the alloy), by the resistance to penetration,
or by other methods.

The more important results of the investigation are as follows:
(1) the formation of mixed crystals is accompanied by an increase in
hardness; (2) the hardness of an unbroken series of mixed crystals
can be represented by a continuous curve showing a maximum; (3)
in the latter case, the maximum of the curve of hardness coincides
with the minimum of the curve of electrical conductivity. (4) At
points corresponding with the extremities of the series of mixed crystals (when the miscibility of the metals is incomplete), there are breaks in the curve of hardness.

Experiments have also been made on the pressures required to force certain plastic binary mixtures in a thin stream through a small opening, and the pressures just sufficient for this purpose are plotted against the composition. These limiting pressures are roughly proportional to the hardness of the alloys. The curves for the isomorphous mixtures of p-dichloro- and p-dibromo-benzenes and of silver chloride and bromide show maxima, but that for zinc-tin alloys shows no maximum, corresponding with the fact that these metals have little or no tendency to form solid solutions.

Finally, when the metals form a chemical compound, the latter may be harder or softer than either of the components, and the curve obtained by plotting hardness against composition may show either a maximum or minimum. A number of examples illustrating this case are cited.

G. S.

Causes Modifying the Dominant Faces of Crystals: Solid Solutions. Paul Gaubert (Compt. rend., 1908, 147, 632–635. Compare Abstr., 1906, ii, 343).—Foreign matter is distributed between crystals and their mother liquor in a definite ratio. The crystalline habit may be modified, not only by crystallisable foreign matter, but by liquid molecules, and even by the mother liquor itself.

Crystals of phthalic acid from aqueous solutions are modified in the same sense by methyl, ethyl, and propyl alcohols, glycerol or aldehyde in small quantities. The minute amount of alcohol in the crystals augments as the proportion of alcohol in the mother liquor increases, but the alcohol is not merely in the state of occluded mother liquor. Methylene-blue, which favours a different crystalline habit in phthalic acid, also hinders the entrance of alcohol into the growing crystals.

R. J. C.

Ultra-microscopic Observations. J. Reissig (Ann. Physik, 1908, [iv], 27, 186–212).—The colloidal solutions of brown, tellurium, selenium, and silver, and of red and blue gold, prepared by Paal (compare Abstr., 1902, ii, 500, 508; 1905, ii, 158) have been examined by means of the ultra-microscope. These solutions contain the sodium salts of protalbic and lysalbic acids (compare Abstr., 1902, i, 653), which act as protective colloids. From the number of particles contained in a given volume, the linear dimensions of the particles of the colloidal elements are calculated. It is found that the number of observable particles is not proportional to the concentration of the dissolved colloid, for all the particles can only be seen in dilute solutions. The number of particles seen through the ultra-microscope is, for a given solution, proportional to the intensity of the source of light used.

The ultra-microscope has also been employed to examine the behaviour of colloidal gold solutions on the addition of hydrochloric acid. The slowness with which flocculation takes place is supposed
to represent the stability of the solution, and for both red and blue solutions, one maximum and two minimum positions of stability have been identified. The position of maximum stability corresponds with the isoelectric point of the solution. In dilute solutions the stability of the colloidal gold is greater than it is in concentrated. The rate at which a given quantity of hydrochloric acid causes flocculation to take place depends on the concentration of the acid, the rate decreasing as the concentration of the acid decreases.

A. J. W.

Lecture Experiment to Demonstrate the Law of Mass Action. Emil Abel (Zeitsch. Elektrochem., 1908, 14, 630—631).—The diminution of the concentration of the hydrogen ions in a solution of acetic acid by sodium acetate is shown by means of the reaction between hydriodic acid and hydrogen peroxide. In acid solutions, iodine is liberated; in almost neutral solutions, oxygen is given off. The difference between a solution of acetic acid, potassium iodide, and hydrogen peroxide, on the one hand, and the same solution with the addition of sodium acetate, on the other, is very striking (compare this vol., ii, 939).

T. E.

Application of the Kinetic Theory to the Metals. G. Reboul (Chem. Zentr., 1908, ii, 473; from Le Radium, 1908, 5, 129—136).—It is assumed that in metals there are free negative electrons and positive atom ions. The free electrons must, then, have a definite tendency to pass from the metal into the surroundings. It therefore follows that at the perimeter there must be a double film metal/gas, and also a potential difference, as in the Nernst theory for the perimeter metal/solution. The equilibrium between the electrons that leave the metal and the electrical energy is influenced by a change of temperature. In this is found a simple explanation of the phenomena of electric capillarity, thermal electricity, and electron rays when substances are strongly heated.

J. V. E.

Velocity of Reaction. Johannes J. van Laar (Chem. Weekblad, 1908, 5, 747—764).—A theoretical paper containing a continuation of the author’s statement of his new thermodynamic theory (this vol., ii, 824).

A. J. W.

(1) The coefficient of distribution in a homogeneous system,
(2) Le Chatelier's principle of the opposition of action and reaction, and the conditions of existence of inverse systems. (3) Equilibrium of heterogeneous systems. (4) The energy relations between the members of a system. (5) The influence of temperature on the equilibrium of the system. (6) The classification of the reactions effecting the equilibrium of the system.

T. H. P.

Equilibria in Quaternary Systems. Frans A. H. Schreinemakers (Proc. K. Akad. Wetensch. Amsterdam, 1908, 11, 138—142. Compare this vol., ii, 571).—The system copper sulphate, ammonium sulphate, lithium sulphate, and water has been studied at 30°. In addition to the three sulphates named, there are two solid compounds involved in the equilibria, namely, CuSO4(NH4)2SO4.6H2O and Li2SO4(NH4)2SO4. The equilibria are represented with the aid of a tetrahedron, all saturation lines and surfaces being projected perpendicularly on one of the side planes of the tetrahedron. J. C. P.

Kinetics of Successive Reactions. Reduction of Chromic Acid by Oxalic Acid. K. Jabłczyński (Zeitsch. anorg. Chem., 1908, 60, 38—49.* Compare Luther and Rutter, Abstr., 1907, ii, 555).—The rate of reaction between chromic acid and excess of oxalic acid in dilute solution has been measured at 15°, the course of the reaction being followed by estimating the concentration of chromic acid in a portion of the solution from time to time with iodide and thiosulphate. The velocity is proportional to the concentration of the chromic acid when different initial concentrations of the latter are used, but the constants calculated according to the unimolecular formula increase considerably during the reaction. Excess of chromic salt does not influence the rate of the reaction.

On the assumption that the reaction takes place in the three stages CrVI $\rightarrow$ CrV (1), CrV $\rightarrow$ CrIV (2), CrIV $\rightarrow$ CrIII (3), and that all three reactions are unimolecular, an equation is deduced from which, by an approximation method, the following values are obtained for the constants of the three successive reactions $k_1 = 0.0344$, $k_2 = 0.1322$, $k_3 = 0.0238$. Other measurements were made in which the conditions were varied considerably, but, although the ratio of the constants calculated from these observations varied somewhat, the order remained the same.

The above conclusion, that the reaction CrV $\rightarrow$ CrI is very rapid and that the other reaction, CrIV $\rightarrow$ CrIII, is comparatively slow, is in accordance with what is known of the behaviour of quinquevalent and quadrivalent chromium salts.

G. S.

Formation of Salts and Basicity of Acids. Giuseppe Bruni (Zeitsch. Elektrochem., 1908, 14, 701—706).—Measurements are made of the conductivity of an acid and of mixtures of the acid and its potassium salt. In each series of measurements, the total concentration of the acid is kept constant, the series extending from pure acid at one end to pure potassium salt at the other. Acetic, formic, monochloroacetic, cyanacetic, and di- and tri-chloroacetic acids are used; they form a series of gradually increasing strength. Each acid is used in eleven different concentrations from $N$ to $N/1024$.

* and Bull, Acad. Sci. Cracow, 1908, 603—620.
The results are given in the form of tables and curves. For acetic acid of normal strength, the molecular conductivity increases as the neutralisation proceeds; in weaker solutions a minimum occurs near the acetic acid end of the curve. This minimum becomes more pronounced, and is found nearer the normal salt end of the curve, with formic acid; with the stronger acids the conductivity of the acid is greater than that of its potassium salt (except in the stronger solutions), and the minimum becomes less marked as the acid used is stronger, until with trichloroacetic acid it disappears altogether, the curves being straight lines. The theoretical discussion of the results is reserved for a later paper.

T. E.

Reduction of Solutions of Potassium Permanganate Acidified with Sulphuric Acid in the Presence of Mineral Salts. T. Waryński and P. Tcheichvili (J. Chim. Phys., 1908, 6, 567—576).—The experiments were made with approximately 1/100 molar solutions of potassium permanganate and 1/30 molar sulphuric acid, and varying concentrations of salts. In some cases observations extended over four months. After the experiment, the amount of change was determined by titration with ferrous sulphate.

Most of the salts used as catalysts exerted an accelerating action in the dark, but a retarding action in daylight. Also, in green and blue light most salts retarded the action, but in orange light a slight acceleration was observed; the retarding effect, therefore, probably depends on the actinic rays.

Rise of temperature also affects the catalytic power of salts on the reaction; it increases the activity of the sulphates of iron, chromium, and aluminium, but retards the action of cadmium sulphate. The activity of certain catalysts, such as ferric alum, increases with the concentration.

G. S.

Esterification of Trichloroacetic Acid. Anton Kailan (Monatsh., 1908, 29, 799—844. Compare this vol., ii, 28).—The esterification of mandelic acid is not retarded by the presence of water up to 4 gram-mols. per litre. The influence of water on the esterification of phenylpropionic acid is much less when trichloroacetic acid is used as a catalyst than when hydrogen chloride is employed.

The relation between the velocity constant and the concentrations of the water and hydrogen chloride in the esterification of trichloroacetic acid is expressed by the equation: \( \frac{1}{k} = 6.554 + 4.880/c + 0.0985/c^2 + (-40.15 + 35.39/c - 0.9550/c^3)w + (-16.90 + 12.98/c - 1.259/c^3)w^2 \). The ratio of the velocity constants with hydrogen chloride and trichloroacetic acid respectively as catalysts is for phenylpropionic acid four times as great as for trichloroacetic acid. The presence of ethyl trichloroacetate does not retard the esterification. The ester is very little hydrolysed by the catalysts in nearly dry alcohol, but considerably in presence of water. The results are not in accordance with the theory of catalysis by hydrogen ions.

C. H. D.

Method of Calculating Atomic Weights. Louis Dubreuil (Compt. rend., 1908, 147, 629—632).—The method introduced by Hinrichs (Abstr., 1907, ii, 345) of calculating the atomic weights of
Connexion between Residual Affinity and Additivity. Walter Peters (Ber., 1908, 41, 3175—3186).—Although the compounds of ammonia with the salts of heavy metals have been fully examined, the compounds with the salts of more strongly electropositive metals have not been so closely examined, owing to their high dissociation pressure. The investigation has been made by means of Ley and Wiegner’s apparatus (Abstr., 1905, 1, 749), as the formation of the additive ammonia compound occurs in an atmosphere of ammonia, and it also allows of the effect of temperature being determined.

Well-defined increase in the number of ammonia molecules absorbed by lowering the temperature was only given by silver chloride, platinocyanide, bromide, and platinocyanide; in the other cases, ammonia was absorbed, and liquids were obtained containing a large percentage of ammonia.

The table summarises the results obtained at the ordinary temperature, I, giving the number of ammonia mols. absorbed, and II the number retained after evacuation:

The platinic salts, in general, absorb more ammonia than the platinous, and the metals, gold or platinum, more than silver or mercury.

An Apparatus for Extraction by Hot Ether. Wilhelm Kulka (Biochem. Zeitsch., 1908, 13, 134—137).—An extraction apparatus somewhat similar to Soxhlet’s, but so modified that the vessel containing the substance to be extracted is surrounded by the ether vapour, its contents therefore being nearly at the temperature of boiling ether (about 30°).
New Forms of Condenser. H. Stoltzenberg (Chem. Zentr., 1908, ii, 277; from Zeitsch. Chem. Apparatur, 1908, 3, 243—245).—The condensers described have the advantage of exposing four cooling surfaces to the vapour, are light and compact, and may be readily cleansed by removing the inner portion with the stopper. The accompanying figures should explain their construction. J. V. E.

A New Aspirating Reflux Condenser. Henri VIGREUX (Bull. Soc. chim., 1908, [iv], 3, 855—857).—This consists of a Liebig condenser in which the water outflow pipe is fused to a small aspirator acting on the principle of an ordinary filter-pump. The air-exhaust tube of this aspirator is connected with the upper end of the inner condensing tube. The latter is provided on its inner surface with points and mounds in order to facilitate condensation. The effect of a current of water through the condenser envelope is thus to produce an upward current of air in the inner condensing tube, and it is claimed that such a condenser placed above an open vessel (basin, beaker or flask) containing the boiling liquid condenses the whole of the vapours, returning the condensed liquid to the vessel even when the liquid consists of ether, alcohol, light petroleum, or carbon disulphide. The apparatus is also of use in reactions involving hydrogen chloride or bromine or iodine vapours. E. H.

A New Aspirating Condenser and Recuperator for Rapid Evaporations. Henri VIGREUX (Bull. Soc. chim., 1908, [iv], 3, 858).—This is simply the condenser described previously (preceding abstract), of which the inner tube is provided, immediately below the outer jacket, with a side-tube arranged to collect the condensed liquid and to convey it through a trap (to prevent the aspirator from drawing air through this side-tube) into a receiver. Solutions in ether, light petroleum, benzene, or carbon disulphide can be thereby rapidly evaporated without risk of ignition. The lower end of the condenser should be placed slightly above the surface of the liquid when the latter is contained in a basin, and in the middle of the neck of a flask when this vessel is used. E. H.

A Simple Form of Sprengel Vacuum Pump. James Arthur Pollock (J. Roy. Soc., New South Wales, 1907, 41, 140—143).—A modified short fall Sprengel pump, in which the raising of the mercury is effected by evaporating the mercury at a lower and condensing it at a
higher level; the mercury on reaching the bottom of the fall tube enters a horizontal tube, the farther end of which is bent vertically upwards; this vertical limb bears a bulb in which the mercury is boiled, the vapours being condensed by passing through a Liebig’s condenser the lower end of which is connected to the fall tube. The apparatus must be used in connexion with an efficient auxiliary pump.

Turbinne Funnel for Mixing Solutions. A. Gawalowski (Zeitsch. anal. Chem., 1908, 47, 697).—The apparatus is intended for the purpose of mixing a reagent with a solution. It consists of a funnel; the stem of which is provided at the bottom with two arms placed at right-angles to the stem and ending in fine curved jets. A glass bulb is attached to the stem just below the funnel, and acts as a float, whilst the apparatus is kept in an upright position by means of a small quantity of mercury contained in a bulb below the two arms. The apparatus is floated in a solution contained in a beaker, and the reagent is poured into the funnel; as it escapes into the solution through the jets, the apparatus is caused to revolve, and the reagent and solution are thus mixed.

Inorganic Chemistry.

Catalysis of Hydrogen Peroxide by Iodine and Iodine Ions. Emil Abel (Zeitsch. Elektrochem., 1908, 14, 598—607).—The reactions between hydrogen peroxide and iodine or iodine ions are:

1. \( \text{H}_2\text{O}_2 + \text{I}^- = 2\text{H}^+ + 2\text{I}^- + \text{O}_2 \)
2. \( \text{H}_2\text{O}_2 + 2\text{I}^- + 2\text{H}^+ = 2\text{H}_2\text{O} + \text{I}_2 \)

The first is very rapid in alkaline solutions, and the second is rapid in acid solutions; in solutions containing a suitable small quantity of hydrogen ions, the two may take place with equal velocity, and the result is then simply decomposition of hydrogen peroxide, the concentrations of the iodine and iodine ions remaining unchanged. The ratio between the quantities of iodine and iodine ions which must be present in order to make the two reactions proceed equally fast depends on the concentration of the hydrogen ions. A large number of experiments, in which the concentration of the hydrogen ions is kept constant by adding acetic acid and sodium acetate to the solutions, are made which are in complete agreement with these views.

Bredig and Walton’s observations (Abstr., 1904, ii, 319) on the catalysis of hydrogen peroxide by neutral iodides are explained by the same reactions, for in this case when reaction (2) has proceeded to a very small extent, the solution becomes alkaline and reaction (1) then proceeds exceedingly fast, the stage at which the two have equal velocity is therefore attained when a very small quantity of iodine has been liberated.

T. E.
Non-existence of a Polymeride of Chlorine. E. Briner and E. Durand (Zeitsch. Elektrochem., 1908, 14, 706—707).—The authors have investigated the effect of the silent discharge on carefully-purified chlorine at a temperature but little above its boiling point. The experimental arrangements could have detected a contraction of 1/2000 of the volume of the gas, but no change was observed. The activity of chlorine observed by Kellner (Abstr., 1902, ii, 640) and Russ (Abstr., 1905, ii, 381) is possibly due to ozone or oxides of chlorine.

T. E.

Absolute Density of Hydrogen Sulphide. Georges Baume and F. Louis Perrot (J. Chim. Phys., 1908, 6, 610—619).—Hydrogen sulphide from several sources, purified by fractional distillation, was employed. The density was determined by the method already described (this vol., ii, 372), except that an oil gauge was interposed between the gas and the mercury.

The mean value of nearly twenty experiments for the weight of a litre of the gas at 0° and 760 mm. is 1.5392 grams. From this result, the atomic weight of sulphur has been calculated by Guye’s method from the critical constants. The mean result is S = 32.070 (H = 1.00775), in excellent agreement with the gravimetric determinations of Richards and Jones (Abstr., 1907, ii, 685).

G. S.

Preparation of Azomide. Johannes Thiele (Ber., 1908, 41, 2681—2683).—Azomide is obtained in good yield by the action of ethyl nitrite on hydrazine in presence of alkali. Hydrazine hydrate (1 mol.) is mixed with 4 N sodium methoxide (1 1/2 mols.), ethyl nitrite (1 1/2 mols.), and ether, and the mixture allowed to remain, first in ice, and then at the ordinary temperature. After twenty-four hours, the sodium azomide is collected and washed. The yield is nearly quantitative. Instead of the hydrate, hydrazine sulphate may be used; this is ground with 3 1/2 mols. of sodium methoxide for six hours, the sodium sulphate filtered off, and the filtrate treated with ethyl nitrite and ether. For the direct preparation of free azomide, hydrazine sulphate is shaken for six hours with aqueous sodium hydroxide and ethyl nitrite; in this way, 80—84% of the hydrazine is converted into azomide. Sodium azomide is also formed by heating hydrazine hydrate with aqueous sodium nitrite, preferably in presence of hydrazine sulphate or sodium hydroxide, but the reaction is slow and incomplete.

J. C. C.

Formation of Nitric Oxide in the High Tension Arc. Fritz Haber and Adolf Koenig (Zeitsch. Elektrochem., 1908, 14, 689—695).—The authors have continued their experiments (this vol., ii, 34) by passing the high tension arc through nitric oxide at about 100 mm. pressure. A platinum wire of 0.01 mm. diameter, stretched across the quartz tube in which the arc is produced, melts when the current is increased to 0.2 ampere. The temperature is therefore not much above the melting point of platinum. Using the same current and passing the gas through the tube at the same rate, the percentage of nitric oxide (about 14.5) leaving the arc is the same whether nitric oxide is used
or a mixture of equal volumes of oxygen and nitrogen. The temperature is at most some hundreds of degrees above the melting point of platinum, and the equilibrium is therefore electrical, that is, due to ionic collisions, and not thermal.

**Interaction of Nitric Oxide and Oxygen.** Wilhelm Holwech (Zeitsch. angew. Chem., 1908, 21, 2131—2135).—Mandl and Russ's observations (this vol., ii, 272) suggest that nitric oxide reacts only slowly with pure oxygen, the reaction being accelerated by the presence of catalysts. As this is of great importance for the practical working up of the nitric oxide which is formed in the electric furnace, the present author has endeavoured to prepare a non-reacting mixture of nitric oxide and ozonised oxygen with the object of studying the effect on it of catalysts. The apparatus employed is figured, and the results of the experiments represented by curves. It is found that 2 vols. of nitric oxide react with 1 vol. of oxygen almost completely at the atmospheric pressure with formation of \( \text{NO}_2 \) and \( \text{N}_2\text{O}_4 \). The velocity of the reaction, by constant volume, is approximately the same for oxygen prepared from air by Linde's method, ozonised oxygen, oxygen from barium peroxide, and oxygen from potassium dichromate and sulphuric acid.

**Action of Nitrous Gases and Oxygen on Water.** Fritz Förster and M. Koch (Zeitsch. angew. Chem., 1908, 21, 2161—2172).—A résumé is given of the work of various authors on the preparation of nitric and nitrous acids from the nitric oxide formed by combustion of atmospheric nitrogen. It is pointed out that the concentration of the nitric acid formed by the action of a mixture of nitrogen dioxide and oxygen on water must reach a limit, which is a function of the velocity with which the equilibrium \( 2\text{NO} + \text{H}_2\text{O} \rightleftharpoons \text{HNO}_3 + \text{HNO}_2 \) is reached, and, therefore, of the concentration of the nitrogen dioxide, since the lower the partial pressure of the dioxide the smaller will be the concentration of its solution in the water, and hence the velocity of its reaction with the water. On the other hand, the larger volume of undissolved gases passing through the solution will cause more rapid evaporation, in which the nitric acid takes part even at concentrations far below 68%. The maximum concentration of nitric acid which can be obtained by the action of a mixture of nitrogen dioxide and oxygen on water, must lie about this percentage, since, when solutions containing higher percentages are evaporated, the nitric acid volatilises more rapidly than the water. For the same reasons, the limit concentration must be the lower the more rapid the current of gas. These views are confirmed by the results now obtained on studying the action on water of mixtures of nitrogen dioxide with oxygen and with air in varying proportions. The apparatus employed is figured, and the results are tabulated.

The formation of nitric acid takes place fairly rapidly until the solution contains about 54% of acid, a concentration corresponding with the composition \( \text{HNO}_3 \cdot 3\text{H}_2\text{O} \), when, in consequence of the greatly diminished amount of free water, the reaction becomes greatly retarded. It is found that, whilst the concentration of a 64·22% acid is raised to 67·6% by the action at 0° of a mixture containing 63·2% by volume of...
nitrogen dioxide, at 60° the concentration is raised by the same mixture, passing into the nitric acid at the same rate and for the same period, only to 65.2%. The higher temperature is the more unfavourable to the reaction, which is, therefore, probably one between water, oxygen, and the bimolecular dioxide, \( \text{N}_2\text{O}_4 \).

The influence of the partial pressure is shown in that, whilst almost the whole of the dioxide of a mixture of 2.5 vols. of nitrogen dioxide with 6.0 vols. of oxygen is absorbed by water with formation of a 37% acid, under the same conditions only 53% of the dioxide of a mixture of 2.5 vols. of dioxide and 122 vols. of oxygen is absorbed with formation of a 27.73% acid.

Whilst at low concentrations the velocity of the reaction is affected only slightly by the rate at which the gases are passed into the water, a marked effect is produced at concentrations over 50% of acid. Equal volumes of a mixture containing 5.0 vols. of dioxide and about 12 vols. of oxygen, when passed into water at the rates of 4.25, 8.5, and 17.0 litres per hour, yielded 58.78%, 55.36%, and 53.95% acids respectively. The bearing of the experimental results on the behaviour of nitrous acid also is discussed.

G. Y.

Molecular Weight and Hydrates of Hypophosphoric Acid. Arthur Rosenheim and Max Prütze (Ber., 1908, 41, 2708—2711). —The controversy between Rosenheim, Stadler, and Jacobsohn (Abstr., 1906, ii, 744) and Parravano and Marini (Abstr., 1906, ii, 744) as to the molecular weight of hypophosphoric acid has led the authors to determine the molecular weights of the methyl and ethyl esters of pyro- and of hypo-phosphoric acids in methyl or ethyl iodide by the ebullioscopic method, with results which indicate that the formulae of the acids are \( \text{H}_4\text{P}_2\text{O}_7 \) and \( \text{H}_2\text{P}_2\text{O}_3 \) respectively.

The monohydrate, \( \text{H}_4\text{PO}_3\cdot\text{H}_2\text{O} \), m. p. 62°, appears to be the only hydrate stable between 6° and 60°; Joly’s anhydride (Abstr., 1886, 662), or Sänger’s hydrate, \( \text{H}_2\text{PO}_3\cdot\frac{1}{2}\text{H}_2\text{O} \), could not be obtained. C. S.

Coagulation of [Colloidal] Arsenious Sulphide by Barium Chloride. Jacques Duclaux (J. Chim. Phys., 1908, 6, 592—595). — When a colloidal solution of arsenious sulphide is precipitated by barium chloride, part of the barium is carried down with the precipitate and the remaining solution is acid. This is usually accounted for on physical lines as being due to absorption of the barium by the sulphide with consequent hydrolysis of the salt (Whitney and Ober, Abstr., 1902, ii, 65), although Linder and Picton (Trans., 1895, 67, 63) showed that the sulphide usually contains excess of hydrogen sulphide, and that in the presence of barium chloride barium sulphide is formed and hydrogen chloride set free.

The author now shows that when a colloidal solution of arsenious sulphide containing excess of hydrogen sulphide, which has been kept well stoppered for five years, is precipitated with barium chloride and filtered, the filtrate contains no hydrogen sulphide, but a certain amount of arsenious acid; the latter corresponds approximately with the amount of hydrogen chloride in the filtrate, and therefore with that of the barium absorbed. The author considers that neither of the above
explanations of the phenomenon are satisfactory; it is probable that there is double decomposition between the barium chloride and the sulphide, perhaps by replacement of an AsO group existing in the sulphide by barium.  

G. S.

Preparation of Carbon Monoxide. Erwin Rupp (Chem. Zeit., 1908, 32, 983).—A known weight of sulphuric acid is heated in a generating flask to 100°, and an equal weight of 98% formic acid is dropped in from a stoppered funnel. A regular stream of pure carbon monoxide is thus evolved; when the action slackens, a gentle heat is again applied by means of a small flame.  

L. de K.

Simple Arrangement for Filling Glass Tubes with Liquid Carbon Dioxide. Alfred Thiel (Chem. Zentr., 1908, ii, 470—471; from Zeitsch. Chem. Apparat., 1908, 3, 240—243).—An arrangement is described for filling evacuated glass tubes with carbon dioxide to allow of the demonstration of the critical temperature of this gas. The glass tube to be filled is placed in a cooling bath of solid carbon dioxide and ether, and is connected by a stout capillary tube to a compression tube, which is regulated by an adjustable head of mercury. Air-free carbon dioxide is admitted to the compression tube by lowering the head of mercury, when, by closing a tap on the inlet tube and opening a tap connecting with the exhausted condensing tube and increasing the head of mercury, the enclosed carbon dioxide is transferred to the cooled tube, where it is condensed. By repeating this operation several times, any required quantity of carbon dioxide may be condensed in an expeditious manner.  

J. V. E.

Argon in Radioactive Zirconium Minerals. A. von Antropoff (Zeitsch. Elektrochem., 1908, 14, 585—586).—The gas extracted from a feebly radioactive Brazilian mineral containing 97% of zirconia consisted mainly of carbon dioxide with smaller quantities of hydrogen and nitrogen and traces of helium and argon. This is the second mineral in which argon has been found; the first was also a radioactive zirconium compound (Trans., 1906, 89, 1568).  

T. E.

Analysis of the Atmospheric Gases Non-liquefiable in Liquid Air. Fréd Bordas and Touplain (Compt. rend., 1908, 147, 591—594).—A modified form of the apparatus described previously (this vol., ii, 430) has been employed for the analysis of the gases which escape liquefaction when liquid air is distilled and the oxygen and nitrogen condensed. A table is given of the wave-lengths of the lines observed in the spectrum of this gas after removal of all the oxygen and nitrogen. This includes, besides those observed by Baly for neon and helium, the red lines of wave-lengths 7267, 7050, 6943, 6732, 6610, 5672, 6535, 6509; the orange lines, 5905, 5890; the yellow lines, 5820, 5808, 5765, and the green lines, 5750, 5722, 5694, 5659, 5569, 5441, 5407, 5348, 5336, which the authors attribute to neon, but which have not been observed previously.

The conclusion is drawn that the gases in the atmosphere non-liquefiable in liquid air consist of neon and helium.  

E. H.
Liquefaction of Helium. H. Kamerlingh Onnes (Proc. K. Akad. Wetensch. Amsterdam, 1908, 11, 168—185; Compt. rend., 1908, 147, 421—424).—The actual work carried out with the object of liquefying helium was preceded by a study of the isothermal lines for such temperatures as can be attained by the use of liquid hydrogen. The results of this study made it very probable that the Joule-Kelvin effect would not only give a decided cooling at the melting point of hydrogen, but that this would be sufficient to make a Linde-Hampson process successful. The construction of the helium liquefer was therefore an imitation of the hydrogen liquefer described in a previous communication.

The helium employed was obtained by heating monazite sand. The gas was then successively exploded with oxygen, cooled with liquid air, compressed, and led over charcoal at the temperature of liquid air. It was then passed through a column of hot copper oxide, compressed over charcoal at the temperature of liquid air, and further led over charcoal under pressure at the temperature of liquid hydrogen, until the gas which had been absorbed in the charcoal and then separately collected no longer contained any appreciable impurity.

On the day before the final experiment, 75 litres of liquid air were prepared, and on the day itself, operations began with the preparation of 20 litres of liquid hydrogen. When the helium (200 litres) had been circulating in the liquefer for about three hours, more than 60 c.c. of liquid helium was obtained. In consequence of the extreme purity of the helium, and by virtue of the special contrivances adopted, the apparatus remained perfectly transparent during the whole experiment.

The liquid helium looks as if it was almost at its critical temperature, and its surface stands out like the edge of a knife against the glass. Evaporation under diminished pressure did not lead to solidification, and the triple point pressure is certainly below 1 cm. The temperature reached in this evaporation was probably about 3° absolute.

The boiling point was found to be 4·3° absolute, but a slight correction is suggested which would make it about 4·5°. The density of the liquid is 0·15; the ratio of the density of the vapour to that of the liquid is 1:11 at the boiling point, indicating that the critical temperature is not much higher than 5° absolute, and that the critical pressure is not much more than 2·3 atmospheres.

The value of $a$, the constant of van der Waals' equation, appears for helium to be about 0·00005, and the value of $b$ is probably about double the value which was expected (0·0005).

Preparation of Colourless Alcoholic Potassium Hydroxide. Adolf Halla (Chem. Zeit., 1908, 32, 890).—Thirty grams of pure stick potassium hydroxide are placed in a bottle with one litre of 95% alcohol, and left at atmospheric temperature until solution is effected, the bottle being shaken from time to time. The clear supernatant liquid is then carefully siphoned off into another bottle, which is stoppered and exposed to diffused daylight. The solution is thereby
bleached in the course of a few days, and remains colourless so long as it is kept in diffused daylight.

**The Partition of Silver between Zinc and Lead.**

G. N. Potdar (*J. Coll. Sci. Tókyö*, 1908, 25, ix, 1—13. Compare Wright and Thompson, Abstr., 1890, 336).—Silver-lead alloys were melted with zinc in an atmosphere of carbon dioxide, the temperature being maintained at 540° by means of a bath of boiling phosphoric sulphide. After stirring, the mass was allowed to remain fluid for five and a-half hours, rapidly cooled, and the silver in the two solidified layers estimated. The whole of the zinc layer has to be taken for analysis, as the distribution of zinc in it is far from uniform, owing perhaps to segregation during cooling. At 540°, silver is about 300 times more soluble in zinc than in lead, and this partition-coefficient is practically independent of the concentration of the silver.

In Parkes' process for the desilverisation of lead, the solid zinc scum is removed at 325—360°. Experiments at this temperature indicate that the removal of silver by the zinc is practically complete, the partition-coefficient at 358° varying in three trials from 1300 to 5700.

**The Silver Hydrogel in Photographic Films.** Lüppo-Cramer (*Zeitsch. Chem. Ind. Kolloide*, 1908, 3, 135—136).—The peculiarities of the silver deposits obtained with different developers, and with gelatin or collodion films, are explained by the more or less completely colloidal nature of the silver, and by adsorption of different substances from the developers (compare this vol., ii, 841).

**Use of Metallic Deposits in Metallography. II. Federico Giolitti** (*Gazzetta*, 1908, 38, ii, 352—357).—The author has applied the method devised by him (Abstr., 1906, ii, 759) to the qualitative study of alloys constituted of solid solutions. When a polished surface of a binary alloy containing mixed crystals either of two metals or of one of them and a compound of the two is immersed in a solution containing ions of the more electronegative or more noble of the two metals, differences of potential are established between the various portions of the surface. The cations of the solution will be deposited in the metallic state on the different parts of the section with a velocity increasing with the concentration of the more electronegative metal. By varying the concentration of the solution and the duration of immersion, or by observing the section under the microscope, the gradual and continuous variations of the metallic deposit on that part of the surface occupied by the mixed crystals can be followed. These variations, which correspond with differences in the concentration of the more noble metal in the mixed crystals, give an immediate indication that the constituent in question is a solid solution, and also permit the observer to judge the heterogeneity of concentration of this solid solution. Various bronzes have been studied in this way, microphotographs of the different sections after treatment with chromic oxide or with copper sulphate solution being given.
Magnesium Oxychloride Formed by Electrolysis of the Residual Solutions from the Manufacture of Potassium Chloride, and its Importance for the Preparation of Bromine by Kossuth and Mehns's Method. Hans Hof (Chem. Zeit., 1908, 32, 993).—It has been found that the yield of free bromine, obtained by electrolysis of the residual solutions from the manufacture of potassium chloride, increases with the concentration of the solution electrolysed. On dilution with water, the electrolysed solution containing free bromine becomes gradually less yellow, and finally colourless, when the solution is found to contain only combined bromine; this may be again liberated by sulphuric acid. If the bromine is first removed by means of an organic solvent, the electrolysed solution, on dilution, becomes alkaline and opaque, in consequence of the separation of magnesium hydroxide. It is considered that magnesium hydroxide, formed during the electrolysis, remains dissolved in the concentrated magnesium chloride solution, forming a basic salt. This is decomposed by water with liberation of magnesium hydroxide, which then reacts with the free bromine. In agreement with this, analytical figures are given, showing that the proportion of bromine present as bromate to the free bromine increases with the dilution of the electrolysed solution.

By electrolysis of a concentrated solution of magnesium chloride, the author has obtained a neutral solution which does not react with bromine. When diluted, it becomes alkaline, and deposits magnesium hydroxide. The concentrated solution slowly deposits a white, amorphous mass, MgCl₂·5MgO (Bender, Annalen, 1871, 159, 341; Davis, Chem. News, 1872, 25, 258), which is stable at 160° and yields magnesium chloride when treated with cold water, but is completely decomposed only by boiling water.

Electrolytic Oxidation of Copper. F. Schmiedt (Chem. Zentr., 1908, ii, 386; from Elektrochem. Zeitsh., 1908, 15, 53—56).—The author has repeated the work of Müller and Spitzer (Abstr., 1907, ii, 174), and finds that, besides cupric oxide and copper peroxide, there is also formed cuprous oxide, which, however, becomes decomposed by the hydrogen peroxide that is also produced. Copper peroxide is formed in largest quantities at the beginning of the electrolysis, when the temperature is low.

Alloys of Copper and Tin. Federico Giolitti and G. Tavanti (Gazzetta, 1908, 38, ii, 209—239).—The results obtained by the authors in studying the freezing points and microscopic appearance of the copper-tin alloys agree, in general, with those of Heycock and Neville (Abstr., 1901, ii, 508; 1902, ii, 261). The freezing-point diagram of these alloys is divided clearly into two parts, the first comprising alloys containing from 0 to 38·34% of tin, and the second, those containing more than 38·34% of tin. Thus the diagram is a complex one, resulting from the combination of the equilibrium diagrams of Cu—Cu₃Sn and Cu₃Sn—Sn. The diagram is discussed in detail.
Copper and Iron Salts in Presence of Alkalis and Acids. Hermann Frischer (Chem. Zeit., 1908, 32, 1005—1006).—Experiments are described to show that the action of sodium hydroxide on a mixture of ferrous and cupric sulphates takes place, contrary to Millberg’s supposition (Chem. Zeit., 1906, 30, 511; 1907, 31, 1143), according to the following equations: (1) \(2\text{CuSO}_4 + 4\text{NaOH} = 2\text{Cu(OH)}_2 + 2\text{Na}_2\text{SO}_4\), and (2) \(2\text{FeSO}_4 + 2\text{Cu(OH)}_2 = 2\text{Fe(OH)}_2\text{SO}_4 + \text{Cu}_2\text{SO}_4\). The action of air on the resulting mixture leads to the formation of ferric hydroxide and cupric sulphate, the whole reaction being represented by the equation: \(2\text{FeSO}_4 + 2\text{CuSO}_4 + 4\text{NaOH} + \text{H}_2\text{O} + \text{O} = 2\text{Fe(OH)}_3 + 2\text{CuSO}_4 + 2\text{Na}_2\text{SO}_4\). Any further addition of alkali must result in precipitation of copper hydroxide. As the equation shows, the copper sulphate acts as the oxygen carrier; in agreement with this view, if potassium sodium tartrate and an excess of alkali are added to the mixture of ferrous and cupric salts, cuprous hydroxide is precipitated in the cold, and on heating is converted into the red anhydride, whilst the ferric salt remains in solution. If a sufficient excess of ferrous salt is present, the cuprous hydroxide is reduced to metallic copper. This reaction may be employed for the detection of ferrous salts.

If a ferrous salt is added to an ammoniacal solution of a cupric salt, ferric hydroxide is precipitated, whilst the blue colour of the solution gradually disappears; the cuprous salt remaining in solution is rapidly oxidised by air. In this case, also, the precipitation of the ferric hydroxide may be prevented by addition of a tartrate or a citrate.

The behaviour of copper and iron salts in presence of ammonia affords a ready means of preparing cuprous solutions for the absorption of carbon monoxide in gas analysis. It is evident, moreover, that, in the separation of iron and copper by means of ammonia, a preliminary oxidation of ferrous salts is unnecessary if the amount of copper present is equal to, or greater than, that of the iron. On the other hand, if the copper is to be estimated colorimetrically, the ferrous salts present must first be oxidised.

In acid solution, cuprous salts are oxidised at the expense of ferric salts, according to the equation: \(\text{Cu}_2\text{O} + 2\text{Fe}_2\text{O}_3 = 2\text{CuO} + 2\text{FeO}\).

G. Y.

Equilibrium in the Reaction between Lead Sulphide and Its Oxidation Products. III. Rudolf Schenck and W. Rassbach (Ber., 1908, 41, 2917—2925).—Previous investigations (Abstr., 1907, ii, 546, 619) have shown that the metallurgically important reactions: (I) \(\text{PbS} + \text{PbSO}_4 = 2\text{Pb} + 2\text{SO}_3\); (II) \(\text{PbS} + 2\text{PbO} = 3\text{Pb} + \text{SO}_3\), are reversible, the equilibrium being conditioned by a definite pressure of the sulphur dioxide, which is dependent on the temperature only. In addition to the two temperature-pressure curves so obtained, a third was indicated, the cause of which forms the main object of the present investigation. The result shows that a basic sulphate, \(\text{PbSO}_4\text{PbO}\), is formed, which, setting up its own reversible reaction, \(2[\text{PbSO}_4\text{PbO}] + \text{PbS} = 7\text{Pb} + 5\text{SO}_3\), accounts for the existence of the third temperature-pressure curve. These three curves divide the whole temperature-pressure diagram into four fields. The final product of all reactions in the first field is lead sulphate, in the second the basic sulphate, and in
the third lead oxide; these three stable phases do not evolve sulphur dioxide with lead sulphide. In the fourth field, no compound containing oxygen is stable with lead sulphide, an impure metal being obtained with evolution of sulphur dioxide. These conclusions are deduced from observations at temperatures below 820°; above this temperature, complications are introduced, owing to the mutual solubility of lead oxide and lead sulphate.

The existence of the basic sulphate, PbSO₄.PbO, is proved as follows. Mixtures of lead sulphate and lead oxide in known proportions are heated to 1020°, and allowed to cool. The freezing-point curve, consisting of many branches, indicates the existence of many compounds of lead sulphate and lead oxide which do not form mixed crystals with one another or with either of the components. Distinct maxima are observed at two points: (966°, 40% PbO) and 951°, 61.5% PbO); the compositions of the mixture at these points correspond with the formula PbSO₄.PbO and PbSO₄.2PbO respectively. The existence of a third basic sulphate, PbSO₄.3PbO, is indicated by the curve, which, however, is only stable below 880°; above this temperature, it passes into PbSO₄.2PbO. The presence of these basic sulphates in the fused masses containing 40–70% lead oxide is indicated by the appearance of long, transparent needles. The only basic sulphate giving in the presence of lead sulphide and a little lead a well-defined temperature-pressure curve is PbSO₄.PbO, as already mentioned; the others react too slowly for any trustworthy data to be obtained.

The following facts have been observed during the investigation. Lead sulphate does not melt below 1100° (compare Ramsay and Eumorfopoulos, Phil. Mag., 1896, [v], 41, 360); an exact determination cannot be made, owing to dissociation into sulphur trioxide. Pure lead sulphate shows a transition point at 850°. Mixtures of lead oxide and sulphate, rich in the former, change in volume at the ordinary temperature, the original dense mass swelling up and crumbling to a coarse powder, in which scales of lead oxide can be detected. The force exerted during the expansion distorted the containing platinum crucible.

C. S.

Compounds of Lead with Nitrous Acid. Alberto Chilesotti (Atti R. Accad. Lincei, 1908, [v], 17, ii, 173–183, 288–295. Compare this vol., ii, 845).—By measuring the E.M.F. of cells consisting of two lead electrodes, one immersed in a solution of a lead salt containing a known concentration of lead ions, and the other in a 0.1N lead nitrite solution, it is found that the concentration of the lead ions in the latter is very nearly equal to their concentration in a lead chloride solution of corresponding concentration (compare Abegg and Labendzinski, Abstr., 1904, ii, 241). The lower conductivity of lead nitrite solutions, compared with those of lead chloride, is hence due, not to a less degree of dissociation (loc. cit.), but to a difference in the mobility of the complex ions.

The conductivity of lead nitrite solutions undergoes a gradual increase, owing to decomposition of the nitrite according to the equation: 3Pb(NO₂)₂ + 2H₂O = Pb(NO₃)₂ + 2Pb(OH)₂ + 4NO; probably a small amount of secondary decomposition occurs with evolution of
nitrous oxide. The solutions examined, after boiling and cooling, deposit nacreous scales of \( \text{Pb(NO}_2\text{)}_2 \cdot \text{Pb(OH)}_2 \cdot \text{H}_2\text{O} \) or \( \text{Pb(NO}_2\text{,NO}_2\text{)}_\text{2} \cdot \text{Pb(OH)}_2 \cdot \text{H}_2\text{O} \).

Attempts to prepare a double nitrite of lead and potassium by mixing hot concentrated solutions of lead acetate and potassium nitrite in various proportions led, in all cases, to crystalline compounds, in which the ratio \( \text{Pb} : \text{NO}_2 \) lies between 1 : 3 and 1 : 4; the excess of lead oxide present is due probably to decomposition of the lead nitrite.

By the gradual addition of freshly precipitated and washed lead hydroxide to a boiling 30% solution of the double nitrite, \( 2\text{Pb(NO}_2\text{)}_2 \cdot 3\text{KNO}_2 \cdot \text{H}_2\text{O} \), the author has prepared the basic lead nitrite, \( \text{Pb(NO}_2\text{)}_2 \cdot \text{Pb(OH)}_2 \cdot \text{H}_2\text{O} \), which can be obtained in the pure, non-hydrolysed condition by gently warming the impure product with a cold saturated, crude solution of the salt, and allowing to crystallise. Under certain conditions, this basic salt separates in the form \( \text{Pb(NO}_2\text{)}_2 \cdot \text{Pb(OH)}_2 \). Study of the action of lead on a lead nitrate solution leads to the confirmation of the existence of the compound \( 4\text{PbO} \cdot \text{N}_2\text{O}_3 \cdot \text{H}_2\text{O} \), prepared by Chevreul (Ann. Chim., 1812, 83, 72) and others.

T. H. P.

Coagulation of Colloidal Aluminium Hydroxide by Electrolytes. Shin-Ichi Kawamura (J. Coll. Sci. Tōkyō, 1908, 25, viii, 1—29).—It has been found possible to determine the degree of coagulation of a colloidal solution of aluminium hydroxide, produced by various electrolytes, by measuring the viscosities of the solutions. The general relations found are not affected to any marked degree by the temperature, concentration of the colloidal solution, or duration of the experiment, and may be summarised as follows: (1) In those cases where coagulation occurs, the relative viscosity shows a marked rise only when the concentration of the electrolytes reaches certain values. From this point, the viscosity increases with the increasing concentration of the electrolyte to a certain limit, and then ceases to be influenced by the further addition of the electrolyte. In some cases, the degree of coagulation increases suddenly, and in others, more gradually, with the increasing concentration of the electrolyte. (2) The colloidal solution of aluminium hydroxide shows anodic cathophoresis; consequently, in accordance with Hardy's rule (compare Abstr., 1899, ii, 567; 1903, ii, 469; 1906, i, 121), only anions are found to exercise coagulating power. (3) With but few exceptions, the coagulating power of an electrolyte increases rapidly with the increasing valency of the anion; this is in agreement with Schulze's rule (compare Abstr., 1883, 295). (4) The highest degree of coagulation produced by various electrolytes differs considerably in different cases, and appears to be a characteristic of the electrolyte.

W. H. G.

Crystallised Iron from a Foundry at Teschen, Austria. Felix Cornu (Centr. Min., 1908, 545—546).—The crystals are about 3 mm. across, and have the form of distorted octahedra grouped along
the three cubic axes (similar to the well-known skeletal growths of magnetite). Anal. I of the crystals, and II of the ground mass of iron in which they are embedded.

L. J. S.

Nature of the Pseudo-solutions of Ferric Hydroxide. III. FEDERICO GIOLITTI (Gazzetta, 1908, 38, ii, 252—258. Compare Abstr., 1906; ii, 857).—The typical or stable ferric hydroxol, prepared by treating washed precipitated ferric hydroxide with acetic acid after keeping it in contact with water for several months and dissolving in water the residue insoluble in acetic acid, is either a ferric hydroxide containing less water than the other hydroxols and the ordinary gelatinous hydroxide, or possibly anhydrous ferric oxide; the latter view is supported by the comparative difficulty with which this hydroxol is dissolved by acids. The hydroxol of Graham, prepared by dialysis, also changes gradually into the stable hydroxol.

T. H. P.

Iodopentamminecobalt Salts. ALFRED WERNER (Ber., 1908, 41, 3007—3015).—The author finds that the substances obtained by Sand und Böckmann (this vol., ii, 44) by the action of iodine on the black nitrosopentamminecobalt salts, to which they ascribe the constitution of a complex metal ammonia containing cobalt atoms with co-ordination numbers 7 and 8, are, in reality, members of the hitherto unknown series of iodopentamminecobalt salts. For example, the product of the action of iodine on black nitrosopentamminecobalt nitrate is a mixture of iodopentamminecobalt nitrate,

\[ [\text{CoI(NH}_3\text{)}_5](\text{NO}_3\text{)}_2 \]

with a little xantho-nitrate; the separation of the two is effected through the dichromates. By treatment with silver nitrate, the former yields aquopentamminecobalt nitrate, thus proving its constitution.

Members of the new series are readily obtained by heating aquopentamminecobalt iodide at 80°. Water is evolved, and the brown product, triturated with ammonium nitrate, yields iodopentamminecobalt nitrate. The chloroide, bromide, iodide, and dichromate are described; they all have a green colour.

C. S.

Relationships between Nickel and Hydrogen. M. MAYER and V. ALTMAIER (Ber., 1908, 41, 3062—3074).—The absorption of hydrogen by reduced nickel has been studied at temperatures between 360° and 560°, and at pressures between 1/15 and 4/5 of an atmosphere. The metal was obtained by the same method as was used by Sieverts (Abstr., 1907, ii, 741), but the conditions of absorption were different, as only small amounts (2.7 grams) of metal were used, and each experiment was allowed to proceed until equilibrium was attained. The amount of gas absorbed was much greater than in Sievert’s experiments; thus at pressures between 1/15 and 4/5 of an
atmosphere, and a temperature of 360°, 1 vol. of the metal absorbs 5·5—50 volumes of gas. The isotherms representing the relationship between the pressure of the hydrogen and the relative number of atoms of hydrogen absorbed, are straight lines; thus indicating that Henry's law holds good, and that the system nickel–hydrogen is bivariant.

The rapidity with which equilibrium is established varies considerably with the amount of hydrogen present.

The solubility coefficient, that is, the ratio weight of absorbed hydrogen in 1 litre of nickel/weight of hydrogen in 1 litre of the gas volume, varies with the temperature.

J. J. S.

Decomposition of Chromic Acid by Hydrogen Peroxide

ERNST H. RIESENFELD and ALFRED WESCH (Ber., 1908, 41, 2826—2835. Compare Abstr., 1905, ii, 825).—The decomposition of chromic acid by hydrogen peroxide was measured in presence of a varying excess of chromic acid. In spite of an excess of from one to one hundred times the theoretical, the amount of oxygen evolved remained constant, averaging 1·94 atoms per molecule of hydrogen peroxide. Decomposition of chromic acid in presence of excess of hydrogen peroxide and increasing amounts of sulphuric acid showed that up to a certain point the reaction remained unchanged, 1 atom of chromium corresponding with about 4·7 atoms of oxygen. Above 2·5N acid, a strength known to react with hydrogen peroxide to form Caro's acid, more oxygen than 5 atoms is evolved, due to a decomposition of the Caro's acid in presence of chromic salts. When the same change is studied in presence of excess of chromic acid, it is found to be far less dependent on the amount of sulphuric acid. Above 2·5N, Caro's acid is formed as before, with the result that slightly less hydrogen peroxide is available, and accordingly less oxygen than 2 atoms is liberated. The concentration of the sulphuric acid when chromic acid solution is dropped into hydrogen peroxide is thus without influence, and perchromic acid, H₃CrO₈, is formed; likewise, when hydrogen peroxide is dropped into excess of a mixture of potassium dichromate and sulphuric acid, the excess of chromic acid is without influence.

Spitalesky’s views (Abstr., 1907, ii, 338, 942) are adversely criticised.

F. F. A.

Preparation of Uranium. FEDERICO GIOLITTI and G. TAVANTI (Gazzetta, 1908, 38, ii, 239—251).—The authors have investigated the various methods of preparing uranium.

The "pure uranyl acetate" of Kahlbaum or Merck is, in reality, a double sodium uranyl acetate, UO₂(OAc)₂NaOAc,2H₂O, which, on ignition, yields sodium pyrouranate, Na₂U₂O₇, as sole product; the latter is also obtained by igniting other uranyl salts of volatile acids containing salts of the alkali metals. When sodium pyrouranate is
heated to redness in a current of hydrogen, it is reduced according to the following equation: \( \text{Na}_2\text{U}_3\text{O}_8 + 2\text{H}_2 = 2\text{NaOH} + 2\text{UO}_2 + \text{H}_2\text{O} \), but it is found to be impossible to remove the sodium hydroxide by washing with water.

The oxide, \( \text{U}_3\text{O}_8 \), can be obtained pure as follows: A solution of sodium uranyl acetate (100 grams) in a mixture of water (4 litres) and hydrochloric acid (50 c.c.) is precipitated by means of concentrated ammonia solution (300 c.c.), the precipitate being washed ten times by decantation with 8—10 litres of 2\% ammonium chloride solution. The precipitate is then re-dissolved in hydrochloric acid, precipitated by means of ammonia solution, and washed as before, these operations being afterwards repeated a third time. On calcining the final precipitate, pure \( \text{U}_3\text{O}_8 \), free from alkali, is obtained.

When a mixture of this oxide with excess of powdered aluminium is thrown on to the surface of fused aluminium maintained at a vivid red heat, not alloys of aluminium and uranium, mixed with alumina as stated by Moissan (Abstr., 1906, ii, 601), but a mixture of uranous oxide, alumina, and aluminium are obtained. When, however, a mixture of ferric oxide with 10\% of the oxide, \( \text{U}_3\text{O}_8 \), is intimately mixed with more than sufficient aluminium filings to reduce both the oxides, and the reaction started by means of barium peroxide and aluminium, the oxide of uranium is reduced to metallic uranium.

T. H. P.

New Element in Thorianite. Masataka Ogawa (J. Coll. Sci. Tokyo, 1908, 25, xv, 1—11).—A new element, which it is proposed to name *nipponium* (Np), has been isolated from thorianite, reinite, and molybdenite. Its equivalent weight is about 50 and atomic weight about 100, so that this element probably fills the gap between molybdenum and ruthenium. Two oxides of the element appear to exist; the higher oxide is an acidic oxide, and is reduced by zinc and hydrochloric acid to the basic oxide; the latter oxide, which in the ordinary course of analysis accompanies aluminium oxide, is separated from this by conversion into a difficultly volatile chloride by heating in a current of chlorine and carbon tetrachloride vapour. The anhydrous chloride so formed dissolves in water to a pale green solution, and gives a characteristic line, having a wave-length of 4882, together with two other feeble lines, in the greenish-blue part of the spectrum. The hydroxide, precipitated by ammonia in the presence of ammonium chloride, is almost white with a pale yellow tinge, and dissolves in alkalis; it becomes nearly black when dried at 100\°. The ignited oxide is brown, and is insoluble in acids. The yellowish-green solution of the hydroxide in hydrochloric acid gives a brown precipitate when boiled with sodium thiosulphate, and a greenish-black precipitate with ammonium sulphide. A solution of the chloride acidified with acetic acid gives a yellowish-brown precipitate with potassium chromate. A brown precipitate is obtained by passing carbon dioxide into a solution of the green mass formed by fusing the oxide with sodium carbonate and potassium nitrate; it dissolves readily in dilute hydrochloric acid. The aqueous solution of the fused mass does not yield a precipitate with ammonia or ammonium.
sulphide, but the addition of acid to the solution containing ammonium sulphide produces a brown precipitate.

W. H. G.

New Element Allied to Molybdenum. Masataka Ogawa (J. Coll. Sci. Tokyō, 1908, 25, xvi, 1—13).—Both molybdenite and thorianite contain a new element, closely allied to molybdenum, which is probably identical with the new tin-group element recently described by Miss Evans (Trans., 1908, 93, 666). The equivalent of the element is about 16.7. It appears to form two oxides; the higher oxide resembles molybdenum trioxide, and yields barium, lead, and silver salts similar to the corresponding molybdates; the mercurous salt, however, forms golden-yellow crystals; the hydrated lower oxide (i) has a graphitic appearance, and is insoluble in hot dilute hydrochloric acid. The oxides are reduced by hydrogen to the metal, which is non-fusible at a red heat; it burns brilliantly in the air, forming the higher oxide. The new element differs from molybdenum in that it is soluble in hot concentrated hydrochloric acid, and gives no colour reaction when its higher oxide is reduced with zinc and hydrochloric acid, either in the presence or absence of potassium thiocyanate.

Thorianite appears to contain, in addition to this new element and nipponium (compare preceding abstract), yet another new element, the oxide of which is radioactive, and dissolves in nitric acid to a bluish-green solution.

W. H. G.

A New Form of "Tin Plague." Rudolf von Hasslinger (Monatsh., 1908, 29, 787—790. Compare Cohen, Abstr., 1900, ii, 212; this vol., ii, 858).—A tinned iron vessel, which had been for two years at 16—45°, showed a crystalline, brittle surface. Other masses of tin, inoculated with small portions of the crystalline tin, underwent the same change, the area affected increasing in diameter 3 to 5 mm. daily. No difference between experiments at 7°, 19°, and 37° could be noted. When tin-foil was inoculated, the change extended through the thickness of the foil. The crystalline tin preserves its appearance up to near the melting point, but becomes normal after melting and again solidifying.

C. H. D.

Reduction of Vanadic Acid by Potassium Iodide. T. Warynski and B. Mdivani (Chem. Zentr., 1908, ii, 763; from Mon. Sci., 1908, 22, [ii], 527—528).—With the object of ascertaining whether the reducing power of potassium iodide in an acid medium is dependent on the electrolytic dissociation of the acid employed, comparable tests have been made, using acetic acid and mono-, di-, and tri-chloroacetic acids. It is found that reduction is effected most readily in the presence of trichloroacetic acid, and least readily in presence of acetic acid. With trichloroacetic acid, the reduction proceeds quantitatively to the tetroxide, and admits of the estimation of vanadic acid by this method.

J. V. E.

The Series Sodium Thioantimonate, Sodium Thiosulphate, and Water. A. D. Donk (Chem. Weekblad, 1908, 5, 767—771).—From mixtures of sodium thioantimonate and sodium thiosulphate in aqueous
solution at 0° and 30°, the following hydrated salts have been isolated:  
\[ \text{Na}_3\text{SbS}_4\cdot 9\text{H}_2\text{O} \; ; \; \text{Na}_2\text{SbS}_4\cdot 9\text{H}_2\text{O} \cdot \text{Na}_2\text{S}_2\text{O}_3\cdot 5\text{H}_2\text{O} \; ; \; \text{Na}_2\text{S}_2\text{O}_3\cdot 5\text{H}_2\text{O}. \]

**Passivity of Platinum.** Rudolf Ruér (Zeitsch. Elektrochem., 1908, 14, 633—634. Compare this vol., ii, 601).—Two platinum anodes in series were placed in 6% and 50% sulphuric acid respectively; after twelve hours their positions were interchanged, and this was continued for seven days; each anode lost 0.7 mg. When the anodes were not moved, they each lost 0.1 mg. In the first experiment, the cathode in the 50% acid gained 1.1 mg.; hence the coating formed in the 6% acid dissolves in the strong acid. If an invisible skin of oxide forms on an anode in the strong acid, it is therefore not the same oxide as that produced in the weak acid.

T. E.

---

**Mineralogical Chemistry.**

**Coloration of Minerals.** Karl Simon (Jahrb. Min., 1908, Beil.-Bd., 26, 249—295).—A review is given of the literature, and experiments made on the coloration of zircon, amethyst, smoky-quartz, tourmaline, and topaz. These minerals are all decolourised when strongly heated in an atmosphere of either hydrogen or oxygen, and the temperature at which the colour is lost depends to some extent on the size of the fragments. The colour is restored on exposing the mineral to sunlight, or to the emanations of radium. The colouring matter is in each case probably inorganic, but its exact nature is unknown.

L. J. S.

**Relations between Quartz, Chalcedony, and Opal.** Hans Leitmeier (Centr. Min., 1908, 632—633).—The following minerals, in a state of moderately fine powder, were heated with a 50% solution of potassium hydroxide at 80° for five hours; the residue was washed with a 50% solution of potassium hydroxide before being washed with water (otherwise some of the dissolved silica is re-precipitated), and the amount of silica in solution was determined:

<table>
<thead>

</tbody>
</table>

Hot water acting for twelve hours on precious opal gelatinises the surface and dissolves 0.22%. It is concluded that chalcedony and
quartz are varieties of the same mineral species, and that chalcedony
does not contain any admixed opal.

L. J. S.

The Reversible Alteration of Cryolite. Felix Cornu (Centr.
Min., 1908, 546—547).—R. Na‘cken (Centr. Min., 1908, 38) has
observed the change of monoclinic cryolite to a cubic modification
at a temperature of 550—570°. The suggestion is made that this
cubic modification (Na₃Al₂F₁₂) is isomorphous with cryolithionite
(Li₃Na₃Al₂F₁₂) (Abstr., 1904, ii, 347).

L. J. S.

Origin of the Boric Acid in the Soffioni of Tuscany.
Giovanni D’Achlaedi (Atti R. Accad. Lincei, 1908, [v], 17, ii,
238—239).—A reply to Nasini (compare this vol., ii, 862).

T. H. P.

Manganese and Iron Minerals from the Crystalline Schists
Jassy, 1908, 5, 87—108).—Fifteen analyses are given of “brostenite”
(Abstr., 1901, ii, 26); they exhibit wide variations, indicating that
the material is not homogeneous. Analyses are also given of wad, and
a manganese and iron carbonate.

L. J. S.

Vorobyevite and the Chemical Structure of Beryls.
Wladimir I. Vernadsky (Bull. Acad. Sci. Petersburg, 1908,
975—976).—The author describes a beryl containing caesium, to which
he gives the name vorobyevite. From the best published analyses,
the conclusion is drawn that the beryls constitute a class of minerals
by themselves. Various members of this class are known, having the
composition: \( p \cdot \text{GlAl}_2\text{SiO}_4 \cdot a \cdot A \), where \( A \) is \( \text{GlH}_2\text{SiO}_4 \), \( \text{GlSi}_2\text{O}_5 \), \( \text{Li}_2\text{SiO}_3 \) or \( \text{Na}_2\text{SiO}_3 \). In beryls not containing alkali metals,
the compound \( 2\text{GlAl}_2\text{Si}_3\text{O}_{12} \cdot (\text{GlSi}_2\text{O}_5) \cdot (\text{GlH}_2\text{SiO}_4) \) predominates. Vorolyevite contains \( 4-65—10-4\% \) of a caesium compound of the type
\( \text{GlAl}_2\text{Si}_4\text{O}_{12} \cdot (\text{GlH}_2\text{SiO}_4) \cdot (\text{Cs}_2\text{SiO}_5) \).

T. H. P.

Analysis of the Microcline from the Pegmatites of
Mesvres. Philippe Barbier (Bull. Soc. chim., 1908, [iv], 3,
821—822).—The pegmatites of the Mesvres valley contain a
beautiful slightly translucent, laminated, milk-white, or pink micro-
cline. The author has analysed specimens of this mineral collected
at Mesvres, and obtained the following results. An analysis by
Damour of specimens of the same microcline found at Broye is given
for comparison:

<table>

E. H.
Analysis of the Christianite of Simiouse. Philippe Barbier (Bull. Soc. chim., 1908, [iv], 3, 822—823).—The cavities in a basalt of Mt. Simiouse, near Montbrison, contain microscopic crystals of christianite and other minerals. The christianite gave on analysis:

<table>
<thead>
<tr>
<th></th>
<th>SiO₂</th>
<th>Al₂O₃</th>
<th>CaO</th>
<th>K₂O</th>
<th>Na₂O</th>
<th>BaO</th>
<th>MgO</th>
<th>Loss on ignition</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>52·10</td>
<td>18·33</td>
<td>4·96</td>
<td>6·89</td>
<td>1·12</td>
<td></td>
<td>traces</td>
<td>16·55</td>
<td>99·95</td>
</tr>
</tbody>
</table>

This mineral thus corresponds closely with the formula

$$\text{Si}_5\text{O}_{14}\text{Al}_2(\text{K}_2\text{Ca}_4) + 5\text{H}_2\text{O}.$$  

E. H.

Aloisiite: a New Hydrosilicate from the Tufa of Fort Portal (Uganda). Luigi Colomba (Atti R. Accad. Lincei, 1908, [v], 17, ii, 233—238).—The silicate contained in the tufa of Fort Portal is of a type extremely poor in silica, and after deducting admixed calcium carbonate and gangue, has the following composition:

<table>
<thead>
<tr>
<th></th>
<th>SiO₂</th>
<th>FeO</th>
<th>CaO</th>
<th>MgO</th>
<th>Na₂O</th>
<th>H₂O</th>

</table>

On the other hand, the fresh decomposition products of a granite from under humus at Schierke closely resembles crude kaolin. The moors must, therefore, be credited with a kaolinising power. G. Y.

Calcium Sulphide (Oldhamite) in the Allegan Meteorite. Wirt Tassin (Proc. U.S. National Museum, 1908, 34, 433—434).—Certain portions of this meteoric stone when treated with acid were noticed to evolve a considerable amount of hydrogen sulphide, and an analysis of the fine powder, freed from magnetic particles, showed the presence of 16·66% CaS in an olivine-enstatite mixture. This constituent could not be detected on a microscopical examination of the stone, and it appears to be present in a finely-divided state in the ground mass.

L. J. S.

Meteoric Chromites. Wirt Tassin (Proc. U.S. National Museum, 1908, 34, 685—690).—Small quantities of chromite are present in
most meteorites; in stones and stony irons rarely as much as 3%, and usually less than 1%, whilst in irons there is generally less than 0·01%. The following nine analyses were made on material isolated from the meteorites named, and eight earlier analyses of meteoric chromites are quoted.

* Trace of TiO₂.

From the Admire pallasite, I was of small, non-magnetic, jet-black grains with a brilliant lustre; and VIII, of bluish-brown, magnetic particles with a dull lustre, isolated from the metallic portion of the meteorite. II, from the metallic portion of the Mount Vernon pallasite, had the form of relatively large (1 mm. across) octahedra with black colour and brilliant metallic lustre, D 4·49; whilst III had the form of minute, rounded grains, frequently enclosed in the olivine, and was brownish-black with a resinous lustre. IV, from the Canyon Diablo iron, had the form of small octahedra and rounded grains, was jet-black with brilliant lustre, and non-magnetic; IX, from the same iron, was in rounded grains, with bluish-black colour and dull lustre, and was strongly magnetic, being really a chromiferous magnetite.

Only the first of these analyses approximates to the typical chromite formula, FeO, Cr₂O₃; the others contain variable amounts of alumina and magnesia, but are of the type RO, R₂O₃.

L. J. S.

---

Physiological Chemistry.

---

The Total Sugar of the Blood. Raphael Lépine and BouluD (Compt. rend., 1908, 147, 226—228).—The total amount of the reducing sugar of the blood can be ascertained by hydrolysing the clot with hydrofluoric acid, and adding the amount of reducing substance thus obtained to that in the filtrate from the clot.

S. B. S.

The Occurrence of Proteose in Blood and Urine. L. Borchardt (Zeitsch. physiol. Chem., 1908, 57, 305—312).—If elastin is given in the food in fairly large amounts to dogs, a proteose (hemielastin) can be detected in the blood, and this is excreted by the kidneys and found in the urine.

W. D. H.
Fatty Degeneration in the Blood. Samuel G. Shattock and Leonard S. Dudgeon (Trans. Path. Soc. London, 1907, 58, 227—255).—In preparations of blood corpuscles hardened in formaldehyde, and stained with Scarlet [? Scarlet R], it is contended that stained particles in the leucocytes in various cases of disease indicate the occurrence of fatty degeneration.

W. D. H.

Estimation of Catalases and Oxydases in Blood. II. Walthier Löb and Paul Mulzer (Biochem. Zeitsch., 1908, 13, 475—495.)—The rate of oxygen evolution was estimated both by the volume and pressure methods already described (this vol., ii, 999). The rate of reaction depends on the quantity of blood added. The curves representing the rate of gas evolution show with small quantities of blood a gradual rise. In the presence of larger quantities, the gradual rise is preceded by a sharper one. The velocity constant is not the same as that of the hæmase studied by Senter, and, from the complexity of the reaction, it is possible that more than one enzyme takes part in the reaction. The rate of action varies with the blood of different animals (rabbits). The action of various oxygen depolarisers was studied. Benzinidine, formaldehyde, and salicylic acid are readily oxidised, but not alcohol.

S. B. S.

The Regulation of the Physico-chemical Properties of the Blood after Injection of Different Solutions. Giuseppe Buglia (Biochem. Zeitsch., 1908, 13, 400—439).—Hypertonic, isotonic, and hypotonic saline and sucrose solutions were injected into dogs, and certain quantities of blood were withdrawn from the animals both before and at different intervals after the injections. Determinations were made of the conductivity and viscosity of the serum, the molecular concentration of the defibrinated blood (by lowering of freezing-point method), and the volume of the corpuscles (by the hæmatocrite). Injections of hypertonic sodium chloride solutions were found to increase the molecular concentration of the blood and conductivity of the serum over a relatively long period, whereas they caused only a very temporary dilution of the blood volume. The changes produced by hypertonic sucrose solutions were only of temporary character, and disappeared much more quickly than those produced by sodium chloride. Isotonic solutions produced but slight changes, and so also did strongly hypotonic solutions, when the volume of the injected liquid and the rate of injection were not great. If, however, the quantity of the fluid and the rate of injection is sufficiently great to produce marked changes in the blood elements, then the physico-chemical changes are demonstrable.

S. B. S.

The Influence of Alkaline Ferro- and Ferri-cyanides on Blood-coagulation. J. Larguier des Bancelis (Compt. rend., 1908, 147, 266—268).—Both potassium ferro- and ferri-cyanides have a marked inhibitory action on the coagulation of the blood and of fibrinogen solutions, the latter acting more powerfully than the former, although it gives no precipitate with soluble calcium salts, whereas the
former does. It is suggested that multivalent negative ions inhibit the coagulation of negative colloids.

Hæmolytic Poisons, especially Bile Salts and Soaps. F. Neufeld and Händel (Chem. Zentr., 1908, ii, 891—892; from Arb. Kais. Gesundh. Amt., 1908, 23, 572—584).—This is a study of the corpuscle-dissolving action of sodium taurocholate, soaps, and potassium hydroxide in comparison with other blood poisons, also of the action of hæmolytic agents on lipoids and proteins, so that their action on the cell-membrane and their destructive action on the whole corpuscle may be distinguished. Lecithin is soluble in a 10% solution of sodium taurocholate, but not in normal potassium hydroxide, or in a 1% solution of an oleate. Cholesterol crystals are soluble in none of these solutions, nor in sapotoxin. The taurocholate dissolves protein. In emulsions of olive oil in physiological salt solution, partly with lecithin and partly with egg-white, the addition of sodium taurocholate produces the liberation of fat, and the solution of lecithin and protein; the other materials used do not produce this effect.

In high concentrations, sodium taurocholate produces in the blood of sheep, goat, and ox an inhibition of hæmalysis, which in lower concentration rises as the concentration increases to an optimum. These three sorts of blood are peculiar in that they are refractory to pure cobra venom; the venom acts hæmolytically in the presence of lecithin. Other kinds of blood (guinea-pig, horse, hen) never show any inhibition unless physiological salt solution is replaced by an isotonic solution of sucrose.

Sodium taurocholate and a series of other hæmolytic agents are capable of uniting with complement, but this is not the case with all blood poisons; it depends on what constituent of the stroma or serum the poison is united to. In the case of sapotoxin, there is, for instance, no union with complement. The destruction of pneumococci by bile salts is also described, so also is "phagocytosis by emulsified fat droplets and the influence of specific anti-sera thereon."

W. D. H.

Hæmolysis. Lào von Liebermann (Biochem. Zeitsch., 1908, 13, 363—364. Compare Abstr., 1907, ii, 973).—In order to produce hæmolysis of the corpuscles of pig's blood, 0.05 c.c. of pure oleic acid, and not oleic acid emulsion, as stated in the previous paper, should be added to 10 c.c. of pig's serum. There is also an error in the same place, as to the order in which different substances should be added to produce hæmolysis.

S. B. S.

Bactericidal Action of Normal Serum. Robert Muir and Carl Hamilton Browning (J. Pathol. Bacteriol., 1908, 13, 76—91).—A distinction is drawn between absorption of complement by bacteria and the bactericidal effect which may follow. Treatment of a normal serum with increasing amounts of a dead emulsion of a bacterium usually produces first a diminution of its bactericidal action on that bacterium, then for that on other bacteria, and finally a diminution of the hæmolytic complement. This shows there is in serum a substance
(bacteriophilic complement) with an affinity for bacteria in general. If the bactericidal action has been reduced as indicated above, it can be more than restored by adding a little of the homologous immune substance.

W. D. H.

Digestion of Fat. III. S. A. Levites (Zeitsch. physiol. Chem., 1908, 57, 46–48. Compare Abstr., 1907, ii, 891)—The glycerol constituent of fat is rapidly absorbed. Absorption begins in the duodenum, and is completed in the neighbourhood of the cecum. In the estimation of glycerol in the intestinal contents, the method of Shukoff and Schestakoff, which depends on the solubility of glycerol in acetone, gives results which are too high. Lewkowitsch’s acetin method is better.

W. D. H.

Nutritive Value of Plant Amides. Ernst Schulze (Zeitsch. physiol. Chem., 1908, 57, 67–73).—A critical review of the difference of opinion which has arisen between Lehmann, on the one hand, and Morgen and Henriques and Hansen, on the other, with reference to the nutritive value of asparagine and similar amides.

W. D. H.

Ferments of Nuclein Metabolism. Alfred Schittenhelm (Zeitsch. physiol. Chem., 1908, 57, 21–27. Compare Abstr., 1907, ii, 109, 564).—Previous work by the author (and by W. Jones) has shown that the formation of uric acid from nuclein is due to a succession of ferment actions. It is now shown that these ferments can be precipitated from organ-extracts by alcohol or by ammonium sulphate, and these ferments, when acting on pure guanine, resolve it quantitatively into uric acid; under favourable conditions, the time may be as short as one to two hours. Bacterial action, which some authors lay stress on, is not the cause of the change.

W. D. H.

Chemistry of Digestion. XXVI. The Behaviour of Different Proteins in the Stomach and Upper Duodenum of the Dog. E. S. London and W. W. Polowzowa (Zeitsch. physiol. Chem., 1908, 57, 113–130. Compare this vol., ii, 870).—Various proteins of animal and vegetable origin are not absorbed in the stomach. Proteins from serum and egg-white are difficult of digestion in the stomach, but most others are rendered soluble to the extent of 78%, the proportion between proteoses, peptones, and residual substances being 59·3, 32·9, 7·8. The juices in the first part of the duodenum act immediately on the soluble products of gastric digestion, resolving them into ultimate cleavage products, whereas the undissolved substances in the chyme are not attacked for some time. The first 6 or 7 centimetres of the duodenum absorb about 6% of the protein.

W. D. H.

Absorption of Protein. Kornél von Körösy (Zeitsch. physiol. Chem., 1908, 57, 267–287).—The view is advanced that the cleavage products of protein digestion cannot be detected in the circulating blood; the percentage of protein in the blood is, however, increased, although whether protein synthesis occurs in the intestinal wall or in
the blood itself is unsettled. The non-coagulable nitrogen in the blood is not increased, as stated by Cathcart and Leathes.

W. D. H.

Muscular Activity and Protein Metabolism. Philip A. Shaffer (Amer. J. Physiol., 1908, 22, 445—455).—The experiments made on two men, and given with full details, showed a rise of total nitrogen excreted in one, and a fall in the other, with muscular work. Work within physiological limits has per se no effect on protein metabolism as indicated by the nitrogen and sulphur of the urine. The excretion of uric acid, urea, ammonia, and creatinine is wholly unaffected.

W. D. H.

The Value of Protein Cleavage Products in the Animal Organism. VII. Emil Abderhalden and Josef Olinger (Zeitsch. physiol. Chem., 1908, 57, 74—79. Compare this vol., ii, 51).—The present experiments on a dog fed with the final cleavage products of casein and meat, confirm results recorded previously that such substances are capable of maintaining weight and nitrogenous equilibrium.

W. D. H.

The Influence of Nitrogen-free Sources of Energy on the Rate of Protein Decomposition by the Organism. W. Falta and A. Gigon (Biochem. Zeitsch., 1908, 13, 267—273).—Dogs of similar size were fed on a standard diet for a time, and then allowed to fast for various periods. They were then given diets consisting, in one set of experiments, of meat alone; in another, of a mixture of meat and levulose; in another, of meat and inosite, and in a fourth set, of meat and alcohol. It was found that the longer the period of fasting before administration of the meal the more rapid the protein decomposition (as estimated by the nitrogen excreted), and the less the protein-sparing action of the carbohydrate when this formed part of the food. The addition of inosite only slows the rate of protein decomposition during the first twelve hours. The time of the fast before the meal has no influence on the action of inosite. Alcohol accelerates the rate of protein decomposition. There is a tendency in the organism to replenish the glycogen stores which had become depleted by fasting, and this is done by obtaining the carbohydrate entirely from the protein when no other glycogen-former is ingested; hence, after fasting, the rapid degradation of protein. The carbohydrate store in the organism has therefore great influence on the time of decomposition. Experiments were also carried out on the effect of superposing various extra diets on a standard diet. It was found that the composition of the standard diet exerts considerable influence on the time of decomposition of the superposed diets.

S. B. S.

The Influence of Nitrogen-free Sources of Energy on the Rate of Protein Decomposition by the Organism. G. A. Pari (Biochem. Zeitsch., 1908, 13, 274—280).—The experiments were similar in character to those of Falta and Gigon (see preceding abstract). The effects of the addition of carbohydrates other than
Lavulose and of fat, on the rate of protein decomposition after a fast, were investigated. It was found that after a long fast, sucrose no longer has the power of slowing the rate of protein decomposition. Fat and \( \beta \)-hydroxybutyric acid, which are not glycogen formers, do not lose, however, their power to retard the rate of decomposition.

S. B. S.

The Influence of the Thyroid Gland on the Rate of Decomposition. G. A. Pari (Biochem. Zeitsch., 1908, 13, 281—284).—Eppinger, Falta, and Rudinger have shown that in dogs without thyroid glands, the protein metabolised during fasting is less, and can be but little diminished by carbohydrates or fat, in contrast to what happens in the normal starving animal. The latter fact is attributed, from other factors discovered, to the depression of carbohydrate metabolism in animals deprived of the thyroid. To throw further light on this matter, experiments similar to those recorded in the preceding abstracts were carried out with animals deprived of the thyroid, which received meals of meat, with or without addition of other food-stuffs, after a period of fasting, and the rate of protein decomposition was determined by estimating the rate of nitrogen excretion. In the normal animal, the influence of carbohydrates on the retardation of the decomposition of protein is diminished by longer periods of fasting. In thyroidectomised animals, long periods of fasting do not diminish this delaying influence to anything like the same extent.

S. B. S.

Influence of Thyroidectomy and Thyroid Feeding on Intermediary Metabolism. Frank P. Underhill and Tadasu Saiki (J. Biol. Chem., 1908, 5, 225—242).—After complete thyroidectomy and parathyroidectomy in dogs, the urinary ammonia is increased beyond what is observed in inanition. The nitrogen in the form of creatinine, purine, and allantoin is unaltered, but creatine is found in the urine. These dogs are incapable of utilising dextrose introduced subcutaneously to anything like the same degree as normal dogs can. The loss of the glands may thus cause a change in gaseous metabolism similar to that seen in cretinism. If normal dogs are fed on thyroid, the urinary nitrogen is increased; there is also a larger output of purine-nitrogen, and a low output of phosphorus. There is, however, but little change in the inter-relation of the urinary nitrogenous constituents.

There is no choline in the blood after thyroidectomy. W. D. H.

The Utilisation of the Energy of Provender as Influenced by the Temperature of the Surroundings, and the Nutritional Condition of Rabbits. W. Ustianzeff and G. Bogajewsky (Biochem. Zeitsch., 1908, 13, 365—399).—Rabbits were fed for a preliminary period on a given diet which was insufficient for the energy needs of the organism. The carbon and nitrogen content, and also the calorific value of this diet and of the excreta, were estimated, and from these data, the loss from the body of fat and protein calculated, and also the calorific value of this loss. The same animal was then given the like diet with the addition of hay, and
the same data obtained as in the preliminary period. From the two sets of data, the physiological food value of the hay was calculated. Experiments were carried out with animals in varying conditions of nutrition, and with the surrounding atmosphere at varying temperatures (0°, 20°, and 30°). It was found that Rübner's law of isodynamic replacement holds good if hay is used as provender, when the physiologically available energy of the latter is only about half of the total energy needs of the animal, and when the animal is kept in an atmosphere of low temperature.

S. B. S.

Secretin. Otto von Fürth and Carl Schwarz (Pflüger's Archiv, 1908, 124, 427—446).—Extracts of intestinal mucous membrane, prepared according to the method of Bayliss and Starling, contain choline. Choline stimulates pancreatic activity, and this action is antagonised by atropine. The secretin of Bayliss and Starling is a mixture of several substances, among which choline occurs. The effect of secretin is not abolished, but only lessened, by atropine.

W. D. H.

Oxidation Processes in Echinoderm Eggs. Otto Warburg (Zeitsch, physiol. Chem., 1908, 57, 1—16).—The research deals with the respiratory process, measured by the amount of oxygen used, in the eggs of Arbacia pustulosa. The figures given show (1) that the amount of oxygen used is from six to seven times greater in fertilised than in unfertilised eggs; (2) this is not mainly used in nuclear division, for at the stage when thirty-two cells are present, the use of oxygen is not proportionately increased from the stage when eight cells are present; (3) moreover, if the continuance of cell division is hindered by hypertonic sea-water, the amount of oxygen used is not markedly altered; (4) an egg-cell breathes 500 (±100) times more vigorously than a sperm cell; (5) hypertonic solutions increase the use of oxygen in unfertilised eggs ten-fold; (6) a transference from hypertonic to normal sea-water also leads to an increase, but not such a marked one; (7) the temperature-coefficient shows the process to be a chemical one.

W. D. H.

A Mono-amino-diphosphatide in Egg-Yolk. Hugh MacLean (Zeitsch. physiol. Chem., 1908, 57, 304).—A mono-amino-diphosphatide (P : N = 2 : 1) analogous to Erlandsen's cuorin, which he separated from heart muscle, can be separated from egg-yolk.

W. D. H.

A Globulin from the Egg-Yolk of Squalus acanthias. Carl L. Alsb erg and E. D. Clark (J. Biol. Chem., 1908, 5, 243—246).—The egg-yolk of the spiny dogfish contains no vitellin, but in its place, a globulin (or a mixture of globulins) which does not contain phosphorus, and, probably, iron is also absent.

W. D. H.

The Assimilation of Phosphorus and Calcium during the Embryonic Life of the Chick. Em. Carpiaux (Bull, Acad. roy. Belg., 1908, 283—295).—Analyses were made of the inorganic and lecithin-phosphorus and of the calcium in eggs in different stages of develop-
ment. It was found that the chick during embryonic life uses chiefly the phosphorus in the egg itself, and if it utilises that of the shell at all, it does so only to a very limited extent. The shell furnishes four-fifths of the calcium necessary for the formation of the chick, and towards the end of the incubation period considerable use is made of this calcium. At this period, destruction of the lecithin takes place, which proceeds pari passu with the utilisation of the lime.

S. B. S.

The Peroxydases of Animal Tissues. Fr. Battelli and Mlle. L. Stern (Biochem. Zeitsch., 1908, 13, 44—88).—Tissue extracts possess the capacity of increasing the rate of oxidation of hydriodic acid by means of hydrogen peroxide. The reaction is manifested when carried out in the presence of starch. In the cases of most tissues, the reaction is masked by the presence of a catalase, which causes a too rapid destruction of the peroxide. If, however, ethyl hydroperoxide is employed instead of hydrogen peroxide, the reaction can, in most cases, be demonstrated, for the catalase of the tissue does not act on this substance, which possesses a similar peroxydase reaction to hydrogen peroxide. Even when the former peroxide is employed, the results are uncertain, and this fact is probably due to the presence of the substances in the tissues, which react chemically with iodine and thus mask the iodine-starch reaction. A more suitable method of investigating the peroxydase reaction of the tissues consists in estimating the amount of carbon dioxide evolved when tissue extracts are treated with ethyl hydroperoxide or hydrogen peroxide and formic acid. The oxidation which then takes place, can occur in acid solutions, under which condition the catalase action on hydrogen peroxide is considerably depressed. The following tissues were investigated, and are enumerated in order of the magnitude of their peroxydase content: liver, kidneys, spleen, lungs, pancreas, lymph glands, ox-muscle, brain, testicles, dog-muscle, thymus, suprarenals, thyroid, rabbits muscle. Blood is also rich in peroxydase. The optimum temperature of reaction in most cases is 38—40°, and the ferment is destroyed at 66° in neutral media and at 55° in acid or alkaline media. In the case of the blood, however, the reaction is much more energetic at 55—60°, and is in other respects anomalous. It is stated to contain a so-called pseudo-peroxydase in the pigment. The formaldehyde is also oxidised under the same conditions as formic acid, but not so energetically. Higher fatty acids, which in vivo are readily oxidised, do not cause evolution of carbon dioxide under the same conditions as formic acid does. For this reason, it is not yet possible to determine the exact biological functions of peroxydases.

S. B. S.

Mode of Oxidation of Phenyl Derivatives of Fatty Acids in the Animal Organism. Henry D. Dakin (J. Biol. Chem., 1908, 5, 173—186).—The subcutaneous injection of sodium phenylbutyrate results in the excretion of phenaceturic acid and a small quantity of β-hydroxy-γ-phenylbutyric acid. No phenylacetone or phenylacetoacetic acid could be found.

If β-hydroxy-γ-phenylbutyric acid is given in the same way, phenaceturic acid is again excreted, and phenylacetone could not be detected.
Administration of phenylacetone results in the excretion of hippuric acid, phenylaceturic acid not being formed. The probable mode of oxidation of phenylbutyric acid in the body is therefore:

\[
\text{CH}_2\text{Ph}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CO}_2\text{H} \rightarrow \text{CH}_2\text{Ph}\cdot\text{CH(OH)}\cdot\text{CH}_2\cdot\text{CO}_2\text{H} 
\]

\[
\text{CH}_2\text{Ph}\cdot\text{CO}\cdot\text{CH}_2\cdot\text{CO}_2\text{H} \rightarrow \text{CH}_2\text{Ph}\cdot\text{CO}_2\text{H}.
\]

Phenylacetic acid is excreted as phenaceturic acid. The intermediate formation of ketones is probably confined to phenylbutyric and phenylpropionic acids, and is not a general reaction. In normal metabolism, probably only part of the butyric and phenylpropionic acids passes through the stage of acetone and acetoepheneone respectively.

Phenylisocrotonic acid is excreted as phenaceturic acid.

\(\beta\)-Dihydroxyphenylbutyric acid is excreted as hippuric acid and a little \(\beta\)-hydroxyphenylbutyro lactone. Mandelic acid is not formed. Dihydroxyphenylbutyric acid therefore does not undergo \(\beta\)-oxidation, but oxidation takes place at the \(\gamma\)-carbon atom. Dihydroxyphenylbutyric acid is not a product of the catabolism of phenylbutyric acid.

Phenylacetone is readily identified by conversion into its \(p\)-nitrophenylhydrazone, which crystallises from alcohol or pyridine in sparingly soluble rosettes of platelets, melting at 145—145.5°.

W. D. H.

Chemistry of the Brains of Birds and Fishes. Alfred Argiris (Zeitsch. physiol. Chem., 1908, 57, 288—295).—Cerebrone from human brain yields 21·83% of galactose; that from birds' brain, 21·75%. A crystalline substance corresponding with Thudichum's sphingosin was also obtained. The birds employed were hens and ducks. Fishes' (cod) brain yielded cholesterol, lecithin, jecorin, and so-called protagon.

W. D. H.

The Chemical Composition of Peripheral Nerves. Fritz Falk (Biochem. Zeitsch., 1908, 13, 153—172).—Both medullated and non-medullated nerves were investigated (sciatic of man, and splenic nerves of ox). The dried medullated nerves were extracted consecutively with benzene, acetone, and ether; the ether-soluble fraction was treated with alcohol, and to the filtrate from the precipitate thus produced, ammoniacal lead acetate in alcohol was added and, after separation of the precipitate and excess of precipitant, alcoholic cadmium chloride solution. By means of the various solvents and precipitants, a series of fractions was obtained, which were partly identified with known substances. The benzene-soluble fraction consisted chiefly of ordinary fats; the acetone extract contained chiefly cholesterol (m. p. 145°); from the ethereal extract a cerebroside separated, and by the precipitation of this extract with alcohol, the cephalins. Ammoniacal lead acetate precipitated another product belonging to the group of cephalins (m. p. 174°). The cerebroside was identical with the cerebrone of Thierfelder (m. p. 209°). The cephalin (m. p. 174°) had the chemical composition of a mono-amino-monophosphatide; it could not be identified with the cephalins already described and obtained from the brain. Only a
small quantity of cadmium chloride precipitate soluble in cold benzene was obtained, and the amount of lecithin appeared therefore to be small and to be accompanied by other phosphatides, which have not yet been identified. A quantitative separation of the various constituents of medullated and non-medullated nerves showed that the former contained 25% cholesterol, 12·4% cephalins, 18·9% cerebrosides, and 2·9% lecithin, whereas the latter contained 47% cholesterol, 23·7% cephalins, 6% cerebrosides, and 9·8% lecithin.

S. B. S.

Weigert's Method of Staining Medullated Nerve Fibres. J. Lorrain Smith, W. Mair, and Jocelyn F. Thorpe (J. Pathol. Bacteriol., 1908, 13, 14—27).—Weigert's method of hæmatoxylin staining, after treatment with potassium dichromate, depends, as osmic acid staining does, on the presence of an unsaturated grouping in the fatty matter present. Cholesterol by itself gives a negative result, although it contains an unsaturated grouping, but it forms myelin figures in contact with soap. These and the crystals described in tissues by C. P. White (composed of cholesterol and fatty acid) stain slowly by the Weigert method. Some results obtained with lecithin are attributed to cholesterol as an impurity in the lecithin used.

W. D. H.

Action of Curare and Physostigmine [Eserine] on Nerve- endings. Action of Barium Chloride on Bird's Muscle. Charles Wallis Edmund and George B. Roth (Amer. J. Physiol., 1908, 23, 28—45, 46—47).—The tonic contraction produced by nicotine in muscles is counteracted by curare; this antagonism is less marked if the nerves are cut, and, as a rule, this lessening of the antagonism coincides in data with the degeneration of the nerve-ending. This may be because denervated muscle has an increased sensitiveness towards nicotine, so that curare is unable to displace it. This view is upheld, and so curare is considered to act, not on the nerve-ending as usually taught, but on the muscle, or on some substance in the muscle of the nature of Langley's receptive substance. As a support to this view, experiments with eserine are recorded. This alkaloid acts in the same way as nicotine, only more slowly. It acts more quickly on denervated muscle, which, therefore, has an increased sensitiveness to it. Curare neutralises the effect whether the muscles are denervated or not. The tonic contraction produced by barium chloride is, however, not antagonised by curare under any circumstances.

W, D, H.

Chemico-physical Investigation of the Crystalline Lens. Filippo Bottazzi and Nob Scalinici (Atti R. Accad. Lincei, 1908, [v], 17, ii, 153—159).—The aqueous humour of the eye contains normally a very small proportion of protein, which is coagulable by heat, but has not the characters of the lenticular protein, and probably has its origin in the blood or lymph. The vitreous body resembles a sponge, the net-work of which consists of protein substances coagulable by heat, and contracts during coagulation, expressing the liquid contained
in the alveoli. This liquid contains a small quantity of a substance precipitable by acetic acid and insoluble in excess of the acid, and is possibly identical with the coagulable protein found in the aqueous humour. Neglecting these small amounts of proteins, the ocular liquids may be regarded as aqueous solutions of crystalloids, mainly of sodium chloride. With regard to their chemical reaction, the ocular liquids behave like a solution of sodium hydrogen carbonate containing sufficient carbon dioxide to render it neutral to phenolphthalein. Excess of carbon dioxide in the ocular liquids renders them acid to phenolphthalein, and may result in the precipitation of the protein as alkali-protein and in the production of superficial opacity of the crystalline lens.

T. H. P.

Amount of Choline in the Lecithin of Heart Muscle. HUGH MACLEAN (Zeitsch. physiol. Chem., 1908, 57, 296—303).—The lecithin of heart muscle when decomposed in aqueous or alcoholic solution yields, on the average, not more than 52% of its nitrogen in the form of choline. Whether a second nitrogenous product is also present is to be investigated.

W. D. H.

Hydrolysis of Chicken Flesh. THOMAS B. OSBORNE and FREDERICK W. HEYL (Amer. J. Physiol., 1908, 22, 433—439).—The entire muscle was used, the substances soluble in water, alcohol, and ether having been removed. The result of hydrolysis shows that the amino-acids occur in different proportions from those given previously by Abderehalden and Sasaki and by Hart in relation to the syntonin of ox flesh. It is, however, doubtful whether the analyses can be fairly compared, especially as the sum total of the products in one case is 60%, and in the other 47%, of the material employed. The most striking feature in the hydrolysis of chicken muscle is the high yield of lysine.

W. D. H.

The Degradation of Acetoacetic Acid in the Animal Body. II. GUSTAV EMBDEN and LOUIS MICHAUD (Biochem. Zeitsch., 1908, 13, 262—266).—It has been already shown that the liver tissue possesses the property of destroying acetoacetic acid. As the latter is excreted in cases of diabetes, experiments were carried out to determine whether this is due to increased production, or to the loss of capacity of the liver in diabetic individuals to destroy the acid, which is probably a normal intermediary metabolism product. For this purpose, experiments were made with the liver of dogs which had been rendered diabetic by the extirpation of the pancreas. Control experiments were carried out with the liver tissue of similar normal animals. It was found that the capacity for destroying acetoacetic acid was the same in the liver of the diabetic as in that of normal animals. The muscular tissue of diabetic animals also retained its property of destroying the acid.

S. B. S.

1907, ii, 637), creatine and creatinine are destroyed or altered by ferment action during autolysis. Mellanby (this vol., ii, 308) finds, on the other hand, that this is not the case if bacteria are excluded. The present experiments undertaken with aseptic and antiseptic precautions confirm the results of the first-named authors.

W. D. H.

The Action of Arsenic on Autolysis. Leo Hess and Paul Saxl (Chem. Zentr., 1908, ii, 338; from Zeitsch. exp. Path. Ther., 1908, 5, 89—93).—The action of arsenic, even when highly dilute, is inhibitory towards the autolytic changes in organs (liver). This is designated negative catalysis.

W. D. H.

The Occurrence of Choline in Thymus, Spleen, and Lymph Glands. Carl Schwarz and R. Lederer (Pflüger’s Archiv, 1908, 124, 353—360).—The occurrence of choline in extracts of thymus, spleen, and lymph glands is proved by chemical and physiological tests. The effect that extracts of these organs have in lowering blood pressure is attributed mainly to choline. Other depressor substances present were not chemically identified, but the suggestion is made that they may belong to the group of histones.

W. D. H.

The Depressor Substance in the Thyroid. Otto von Fürth and Carl Schwarz (Pflüger’s Archiv, 1908, 124, 361—368).—The substance present in thyroid extracts which depresses arterial pressure is identified as choline.

W. D. H.

The Chemistry of Amyloid Degeneration. Olav Hanssen (Biochem. Zeitsch., 1908, 13, 185—197).—The amyloid tissue (the “sago granules” of the spleen) was separated from the surrounding tissue by a mechanical method. The product obtained in this way was, when dried, a yellow or brown powder, which gave the usual blue coloration with iodine after addition of sulphuric acid, and the ordinary protein reactions. The C: N ratio in three different preparations was constant (approximately 4); these contained no oxidised sulphur, and consequently no conjugated sulphuric acid, and the observation of previous observers, who noted the presence of chondroitin-sulphuric acid, appears to be incorrect. The amyloid tissue is, in general, very resistant to the action of proteolytic ferments; it is changed, however, by the action of pepsin and hydrochloric acid into a product which is soluble in dilute ammonia, but which no longer gives the iodine reaction. The capacity to give this reaction is also lost on treatment of the tissue with alcalis.

Although the mechanically separated amyloid tissue itself contained no oxidised sulphur, the organs from which it had been obtained did. It seems probable that the chondroitinsulphuric acid or a similar substance is formed at the same time as the amyloid tissue. No other marked differences between amyloid and normal tissue were ascertained.

S. B. S.

So-called Fatty Degeneration of the Suprarenal. Charles Powell White (J. Pathol. Bacteriol., 1908, 13, 11—13).—The
presence of fats and lipoids in the suprarenal cortex is a physiological condition. The cortex is believed to be engaged in the secretion of cholesterol, lecithin, and fats, and this has some connexion with the regulation of growth and development. W. D. H.

Silicic Acid in Whartonian Jelly. Franz Frauenberger (Zeitsch. physiol. Chem., 1908, 57, 17—20).—The amount of silicic acid in the Whartonian jelly of the human umbilical cord is less than Schulz stated it to be. According to Schulz, the ash contains 0·6% of the acid; the figure should be 0·028. W. D. H.

The Action of Electrolytes on the Rhythmic Movements of Medusae. I. Action of the Salts of Sea-water. Albrecht Bethe (Pflüger's Archiv., 1908, 124, 541—578).—An investigation of the various salts, alone and in combination, on the movements of jelly fish was carried out on the lines of the well-known work of Loeb and others. The relative importance of the various ions is discussed. Thus sodium chloride by itself first stimulates and then paralyses the movements; this action is reversible; potassium stimulates the rhythm; magnesium paralyses it; the paralysing action of calcium only occurs when it is highly concentrated. W. D. H.

The Circulation of the Bile. Gustav Bayer (Biochem. Zeitsch., 1908, 13, 215—233).—Although the bile salts are strongly toxic to individual organs, they are being continually resorbed from the intestine and entering the circulation. They then exert no toxic effect, even in cases of jaundice. This is due to the fact that the salts are changed in some manner by the serum proteins, and are thereby deprived of their toxic character. This was confirmed by investigating the toxic action of bile salts, when alone and when mixed with serum, on muscular tissue, the central nervous system, the circulation, and also the haemolytic action. The change effected by serum on the bile salts which deprives them of their toxic character is probably of a physical nature ("colloidal envelopment"). Serum which has been previously warmed acts more efficiently in this respect than unwarmed serum. This action between serum proteins and bile salts produces a disappearance of the complement, a fact which was ascertained by allowing red blood corpuscles to act on amboceptor and complement containing sera in the presence of bile salts which had themselves been deprived of their haemolytic action by means of an inactive serum. The change in the bile salt molecule wrought by the serum renders excretion difficult, and a bile salt thus changed will not readily dialyse. The liver cells exert a great affinity for the bile salts, and the fixation of cholates by these cells can be demonstrated in vitro. S. B. S.

Bile Haemolysis. III. The Reasons of the Increased Rate of Bile Haemolysis in Concentrated Salt Solutions. Gustav Bayer (Biochem. Zeitsch., 1908, 13, 234—242).—It was shown that bile salts diminish the surface tension of salt solutions to a greater extent than they do that of pure water. Substances which lower the surface
tension of a solution tend to concentrate on the surface. The bile salts tend in emulsions of blood corpuscles to collect round the erythrocytes, and the more rapidly the more concentrated the salt solution used as their solvent. In concentrated salt solutions, there is a more rapid entry therefore of the bile salts (which bring about haemolysis by their action on the lipoids) than in water. S. B. S.

The Influence of Tolylene-2:4-diamine on the Secretion of Cholesterol in the Bile. Chasoburo Kusumoto (Biochem. Zeitsch., 1908, 13, 354—362).—The polycholia, following administration of tolylene-2:4-diamine, is stated to be due to the destruction of blood-corpuscles; thus supplying material for bile pigment which is derived from hemoglobin. As the corpuscles also contain cholesterol, it might be expected, therefore, that administration of tolylene-2:4-diamine would also lead to an increased elimination of this substance in the bile. This the author has experimentally shown to be the case. The experiments were carried out on dogs with biliary fistula. S. B. S.

Haemolytic Factors in Milk. Janet E. Lane-Claypon (J. Pathol. Bacteriol., 1908, 13, 34—37).—Milk, when fresh, contains both complement and amboceptor in about 1/10 the strength of that in serum. In order to obtain haemolysis, "ox-colloid" must be added; this confirms Bordet's views. "Ox-colloid" is prepared by heating ox-serum to 56% for thirty minutes, and then removing the amboceptor by adding about twice the amount of corpuscles which it can sensitise. The mixture is incubated for one hour, and centrifuged; the supernatant fluid is "ox-colloid."

On adding blood-corpuscles to milk, the cream picks them up and carries them to the top. This red plug does not occur if the milk has been previously heated for a few minutes to 70%, and this circumstance may be used to detect heated or pasteurised milk. W. D. H.

The Degree of Acidity of Urine. Adolf Jolles (Biochem. Zeitsch., 1908, 13, 177—184).—The concentration of the hydrogen ions was estimated by determining the rate of hydrolysis of sucrose caused by it at various temperatures. At higher temperatures, for example, at 90°, the results were complicated by the decomposition of the urea and the formation of ammonium carbonate. For this reason, the urea was estimated in the urine both before and after the process of inversion, as also the acidity (by titration) and the mono- and di-phosphates. The results indicated that the concentration of hydrogen ions is very small, and corresponds very closely with that due to monosodium phosphate present in the urine. Owing to the decomposition of urea, trustworthy results by sugar catalysis are only obtainable when the temperature of the experiment does not exceed 37°. S. B. S.

The Rate of Elimination of Chloroform. D. Noël Paton (Proc. Roy. Soc. Edinburgh, 1908, 28, 472—496); D. Noël Paton and Dorothy E. Lindsay (ibid., 497—502).—The experiments were performed on dogs and rabbits; the blood and tissues, as well as the excreta,
were examined, and the analytical results given in detail. It was found that when chloroform is given by the respiratory passages, it is first dissolved in the blood, and thus acts on the nerve-centres, excess being rapidly eliminated. If it is subcutaneously administered, and still more if given by the stomach, the assumption is slow, more stable compounds are formed, and elimination is consequently delayed. The drug has thus more time to produce a slow toxic effect upon the protoplasm of the tissues. The onset of late chloroform poisoning after anaesthesia is due to delayed elimination brought about by unusually firm fixation or by respiratory deficiency. W. D. H.

Excretion of Creatinine in Man. C. J. C. Van Hoogenhuyze and H. Verploegh (Zeitsch. physiol. Chem., 1908, 57, 161—266. Compare Abstr., 1906, ii, 186).—An extensive series of estimations of creatinine are recorded in health and disease, which confirm, in the main, the conclusions drawn by Folin and other workers. Mellanby’s view, that creatinine is converted into creatine in the liver, is confirmed, as is also the statement of Gottlieb and Stangassinger that substances (probably ferments) occur in the liver and other organs which transform creatine into creatinine. If the liver is largely destroyed (for instance, by cancer), large amounts of creatine instead of creatinine pass into the urine. The lowering of hepatic activity will explain the presence of creatine in the urine in fever and hunger. In the healthy tissues and blood, creatinine is never found, as it is removed so quickly by the kidneys.

Excretion of Creatine and Creatinine in Health and Disease. Philip Shaffer (Amer. J. Physiol., 1908, 23, 1—22).—Normally, from 7 to 11 mg. of creatinine nitrogen are excreted per kilo of body-weight. This is constant from day to day and from hour to hour; it is not influenced by the volume of the urine, or by the total nitrogen excreted. This creatinine coefficient is parallel to the muscular efficiency of the individual, and in many diseases it is lowered. Creatinine is not an index of total endogenous protein catabolism, but of some special process of normal muscular metabolism. Mellanby’s view that the liver is the seat of its formation, whence it reaches the muscle, is dissented from. The creatinine excretion is slightly increased in acute fevers; here it is not parallel to muscular efficiency. Unless creatine occurs in the food, it is absent from normal urine; it may be excreted in acute fevers, in the acute stages of exophthalmic goitre, by women during involution of the uterus, and in other conditions in which there is a rapid loss of muscle protein. W. D. H.

Cystinuria with Diamines. Francis H. Thiele (Trans. Path. Soc., 1907, 58, 255—263).—A case of cystinuria is recorded; tyrosine and other mono-amino-acids were absent from the urine. The urine contained cystine, and, in addition, excess of neutral sulphur, and also cadaverine; putrescine was present in the faeces. All the cystine was apparently derived from tissue catabolism, since starvation, changes of diet, and administration of cystine made no difference in the amount
excreted. The conclusion is drawn that the tissues were deficient in a ferment which normally removes sulphur from thio-amino-compounds.

W. D. H.

Diuresis. XV. Excretion of Sodium Chloride in Phloridzin Diabetes. JOH. BIBERFELD (Pfüger's Archiv, 1908, 124, 532—540. Compare Abstr., 1906, ii, 564).—Polemical. A reply to Loewi and Neubauer on their criticisms of the author's previous work.

W. D. H.

Morphine Diabetes. W. SPITTA (Chem. Zentr., 1908, ii, 343; from Zeitsch. exp. Path. Ther., 1908, 5, 94—104).—The reducing substance often found in the urine of those dosed with morphine is probably levulose, although it is stated to be optically inactive. Dextrose, glycuronic acid, and pentose are absent.

W. D. H.

Gout. HEINRICH KIONKA (Chem. Zentr., 1908, ii, 342; from Zeitsch. exp. Path. Ther., 1908, 5, 131—141, 142—146).—After the administration of uric urid, glycine can be detected in the blood. A crystalline derivative of it, naphthalenesulphonylglycine, was prepared, which showed all the crystallographic constants of the same substance prepared synthetically. A crystallographic description is also given of the corresponding derivatives of other amino-acids (leucine, alanine, &c.).

Feebly alkaline solutions of glycine, alanine, leucine, and allantoin catalytically accelerate the precipitation of acid urates from solutions of uric acid. The presence of such substances in gout is therefore harmful.

W. D. H.

High Temperatures and Heat Stroke. HARVEY SUTTON (J. Pathol. Bacteriol., 1908, 13, 62—73).—In the human subject, the rise of internal temperature, due to exposure to high external temperature, is accompanied by a marked rise in total respiratory exchange and a rise in the respiratory quotient; this probably points to a greatly increased combustion of carbohydrates.

W. D. H.

Crystals in Tumours. CHARLES POWELL WHITE (J. Pathol. Bacteriol., 1908, 13, 3—11).—Crystals consisting of a loose combination of cholesterol with fatty acids, lecithin, or other substances occur in or among the cells of malignant tumours and in some other conditions. These crystals appear to be associated with cell proliferation rather than with degeneration. In degenerated areas, the crystals formed are mostly either cholesterol, fatty acids, or fats. It is suggested that cholesterol is associated with the regulations of cell proliferation.

W. D. H.

Peptonisation in Raw and Pasteurised Milk. RACHEL H. COLWELL and HENRY C. SHERMAN (J. Biol. Chem., 1908, 5, 247—252).—The conclusion is drawn that pasteurisation is not an ideal process as a safeguard against infectious disease. Heating may destroy acid-producing organisms, but leaves intact putrefactive, ammonia-forming, and peptonising organisms. Pasteurisation at high temperatures (75—90°)
has less restraining effect on peptonisation and development of offensive odours than heating to 60°. The amount of ammonia does not always run parallel with intensity of the putrid odour. The determinations of intensity of odour, and also of peptone by the biuret reaction are admittedly rough, and, although conclusions are drawn in reference to infectious disease, no experiments or observations on pathogenic organisms appear to have been made.

W. H. D.

Action of Wines and of Alcohols on the Frog. VITTORIO NAZARI (Atti R. Accad. Lincei, 1908, [v], 17, ii, 166—172).—In small doses, alcohols have no apparent physiological action on frogs, but in larger doses they produce narcosis or complete muscular relaxation, which lasts a longer or shorter time according to the concentration of the alcohol employed and to the size of the frog. Complete recovery takes place from this narcosis, but larger doses of the alcohols cause death. In the following list, the alcohols examined are arranged in the order of increasing narcotic power: ethyl, methyl, propyl, isobutyl, isobutyl, amyl. The alcoholic content of a wine can be determined roughly by ascertaining at what dilution it just causes or fails to cause narcosis, 1 c.c. of 4% ethyl alcohol having no narcotic influence even on small frogs; in this connexion, the presence in the wines of small proportions of highly narcotic higher alcohols must be borne in mind.

T. H. P.

The Mechanism of the Action of Arsenic Preparations on Trypanosomes in the Animal Organism. II. MARTIN JACOBY and ALBERT SCHÜTZ (Biochem. Zeitsch., 1908, 13, 285—298).—Mice received injections of atoxyl, or of arsenious acid, and were then inoculated with Nagana trypanosomes. The trypanosomes from these animals were then inoculated into other animals similarly treated. This process of transference from animal to animal which had been injected with atoxyl or arsenious acid was repeated several times, and the sensitiveness of the trypanosomes obtained after many animals had been thus inoculated towards both arsenious acid and atoxyl was investigated, the experiments being carried out in vitro. No marked difference in this respect between these and normal trypanosomes could be ascertained.

S. B. S.

The Behaviour of Iron Arseno-paranucleate and of Arsenious Acid in the Organism. ERNST SALKOWSKI (Biochem. Zeitsch., 1908, 13, 321—338).—The arseneo-paranucleate was obtained by precipitating an arsenical peptic digestion product of caseinogen by ferric ammonium sulphate. There is evidence that the product obtained in this way is a definite compound, and not a mixture of ferric arsenate and paranucleate. Its behaviour in the organism was investigated by examining the urine after its administration, and determining the rate and the form of the arsenic excretion. It was found that if alcohol is added to alkaline urine, the arsenic in inorganic form is precipitated, whereas that in organic combination dissolves in alcohol. Iron arseneo-paranucleate is readily resorbed from the digestive tract, a fact which confirms the assumption that the arseneo-paranucleate is a definite
compound, for arsenate of iron is not readily resorbed. The arsenic excreted is chiefly in the form of an organic compound, although small quantities of inorganic arsenic can be detected in the urine in the first days after the administration. The arseno-paranucleate is also resorbed after subcutaneous injection. After administration of arsenious acid, both organic and inorganic arsenic is excreted, the former being in excess of the latter. Of ingested arsenious acid, at least 62% is excreted in the urine after six days. In some experiments, arsenic was detected in the urine of animals to which no arsenic compound had been directly administered; this is due to the small arsenic content of certain vegetables which served as food.

S. B. S.

Physiological Action of Choline. GEORG MODRAKOWSKI (Pflüger's Archiv, 1908, 124, 601—632).—This alkaloid appears to be less toxic than is usually considered to be the case. Many of the physiological effects, including the lowering of blood-pressure, usually attributed to it occur only in commercial specimens, but not in the pure substance. The action of the impurity is antagonised by atropine; hence it is that commercial choline produces, after atropinisation, a rise of blood-pressure, which is always the result if the pure alkaloid is employed. Pure specimens rapidly develop the impurity. The experiments were made with choline synthetically prepared.

W. D. H.

The Behaviour of the Brain towards Strychnine. TORATA SANO (Pflüger's Archiv, 1908, 124, 369—380).—The grey cortex of the human brain neutralises the toxic action of strychnine; this is especially marked in the motor areas, and the action is attributed in the main to the giant pyramid cells.

W. D. H.

Action of Strychnine and Caffeine. TORATA SANO (Pflüger's Archiv, 1908, 124, 381—391).—From experiments on frogs, the conclusion is drawn that strychnine has an anaesthetic as well as a stimulating action; the former manifests itself mainly on the pain receptive elements of the central nervous system, and the latter on the tactile elements; the stimulating action outlasts the anaesthetic, and is slower of development. Similar conclusions are drawn regarding the action of caffeine.

W. D. H.

The Liver in Chloroform Necrosis (Delayed Chloroform Poisoning). H. GIDEON WELLS (J. Biol. Chem., 1908, 5, 129—146).—Rapid autolysis of the liver cells, sometimes follows chloroform anesthesia in man. A third or more of the solids may disappear in a few days, and the liver contains proteoses, purine bases, polypeptides, and amino-acids. The sulphur in insoluble form is unaltered, but, in spite of loss of nuclear structure, the insoluble phosphorus is increased. The distribution of nitrogen in mono- and di-amino-acids in the coagulated liver proteins does not differ from the normal. Fatty metamorphosis is present in moderate degree; the increase in ether extractives is due to infiltration with simple fats; the lecithin is
slightly decreased, and the amount of cholesterol unaltered. There is
less replacement of proteins by water, and more fatty infiltration than
in acute yellow atrophy.
W. D. H.

Chemistry of Vegetable Physiology and Agriculture.

The Chemical Changes Involved in the Assimilation of
Free Nitrogen by Azotobacter and Radiobacter. Julius Stoklasa [with Adolf Ernest, Franz Straňák and Eugen Vítek]
(Centr. Bakt. Par., 1908, 21, ii, 620. Compare this vol., ii, 880).—
The activity of the culture decreases as it ages, doubtless because of
the accumulation of acid. Quantitative experiments made to trace
the fate of the dextrose were only partly successful; starting with
15.9 grams of dextrose, 7.9 were converted into carbon dioxide, 0.3
into ethyl alcohol, 0.2 into formic acid, 0.7 into acetic acid, 0.2 into
lactic acid, leaving a balance of 6.5 unaccounted for, part of which,
however, is assimilated into the cell wall of the organisms.
Contrary to the statements of Severin and Krzemieniewski,
hydrogen is invariably liberated, and, if sodium nitrate has been
added, a certain amount of nitrite and of ammonia is produced.
The author has made an analysis of the bacterial mass and found
N 11.3%, and ash 8.6%; the latter contained P₂O₅ 4.9, and K₂O 2.4,
these two substances forming practically the whole of the ash.
E. J. R.

Fixation of Atmospheric Nitrogen by Pure Cultures of
Compare Stoklasa, this vol., ii, 880).—The author supposed previously that the active agent in nitrogen fixation is not Azotobacter, but
Bacillus radiobacter, almost invariably found with it. His subsequent
experiments have demonstrated the incorrectness of this view, and it
is now clear that Azotobacter fixes nitrogen. The present paper deals
with an improvement in technique, whereby it is possible to obtain a
better idea than formerly of the distribution of the organism.
It is customary to use a sugar as the source of carbon in culture
solutions, but the author finds that calcium malate is better; his
solution was 100 tap water, 2 calcium malate, 0.05 K₂HPO₄. Plates
can be made if 1 to 2 parts of agar agar are also added; on
these, a larger number of organisms develop into colonies than on
any other plates, so that a more exact estimate of the number of
Azotobacter present in a sample of soil can now be made. Instead of
calcium malate, the lactate, acetate, or propionate can also be used,
but in these media the organisms soon lose their power of growth, and
re-inoculation to obtain pure cultures cannot be continued for long.
Growth is also slow when calcium citrate, tartrate, or succinate is
used, and there is no growth when calcium glycollate is supplied.
The amount of nitrogen fixed per gram of calcium salt oxidised was 4.9 mg. with the propionate, 2.8 mg. with the acetate, 2.6 mg. with the malate, and 1.8 mg. with the lactate. About 7 mg. are fixed for each gram of sugar oxidised when sugar is used as the source of carbon.

When calcium malate plate cultures are made of soil extracts, it is not usual to find colonies of Azotobacter, because only a small proportion survive and develop on plates, but when soil adhering to the roots of leguminous plants is examined, a number of colonies are produced, showing that a distinct relationship exists between the distribution of Azotobacter and the Leguminosae. E. J. R.

Variation of the Rate of Disinfection with Change in the Concentration of the Disinfectant. Herbert Edmeston Watson (J. Hygiene, 1908, 8, 536—542).—Miss Chick’s results on the laws of disinfection, in which she showed that the disinfection is strictly analogous to a chemical reaction in which individual bacteria play the part of molecules, can be expressed by a mathematical formula, the use of which is illustrated by one of the problems worked out as follows: A solution of phenol containing 10 parts per 1000 disinfects a culture of Bacillus paratyphosus in twenty-five minutes; another solution takes thirty-five minutes. What is the strength of the second solution? Let the strength of the second solution be \( x \); for phenol, \( n = 5.5 \). Therefore \( 5.5 \log 10 + \log 25 = \text{constant} = 5.5 \log x + \log 35 \). From this \( x = 9.4 \).

W. D. H.

Protein Formation in Ripening Seeds. N. Wassilieff (Ber. deut. bot. Ges., 1908, 26a, 454—467. Compare Abstr., 1901, ii, 185, and Nedokutschaffe, Abstr., 1902, ii, 281; 1903, ii, 508; Zaleski, 1905, ii, 549).—A continuation of work on the source and method of formation of protein in ripening seeds. As the result of a series of determinations, the amounts of nitrogen present in various forms, for example, as protein, asparagine, amino-acids, substances precipitated by phosphotungstic acid, &c., in (1) seeds at various stages of ripeness, (2) whole fruits, (3) husks of fruits, (4) whole leaves, (5) laminae, and (6) petioles, of Lupinus albus, the following principal conclusions are drawn.

After the removal of fruits from the plants, protein formation takes place in the former whether they are kept in the dark or in the light, and at the expense of asparagine, present in the fruit as plucked. The amino-acids at first increase slightly in amount, especially if the fruits are kept in the dark, doubtless as the result of protein decomposition, but eventually they are also used up, being probably transformed into asparagine, and then into protein. Organic bases play much the same rôle as amino-acids.

In the foregoing changes, the seeds become gradually richer in nitrogenous material, due to movement of nitrogenous substances from the husks of the fruits to the seeds. At the same time, the seeds become enriched with protein at the expense of the husks, so that the protein of the ripe seeds is, in part, derived from amino-compounds initially present in them when the fruits are plucked, and,
in part, from amino-compounds subsequently formed in the husks. Seeds separated from the husks, and kept either dry or damp, form some protein from asparagine and other amino-compounds originally present in them.

T. A. H.

The Rapid Change in Composition of Certain Tropical Fruits during Ripening. H. C. Prinsen Geerligs (Proc. K. Akad. Wetensch. Amsterdam, 1908, 11, 74—84).—The fruits investigated are commonly gathered in an immature state; within a few days they become tender and palatable; a few days later, however, they become over-ripe, and change to a soft, unpalatable mass. Experiments with bananas (Musa) showed that during the ripening process there is an evolution of carbon dioxide and water, and a considerable conversion of starch into sugar. The composition at the various stages is as follows:

Quite similar results were obtained with the mango (Mangifera) and the tamarind (Tamarindus).

Oxygen is necessary for the ripening process; bananas will keep their starch intact if surrounded with an atmosphere of nitrogen. The author, therefore, considers sugar production to be a vital process, although he succeeded in demonstrating the presence of an enzyme capable of decomposing starch.

Sapodilla (Achras sapota) does not fall into line with the above-mentioned fruits; the amount of sugar before and after ripening remains unaltered, and the change appears to be mainly a softening of the hard pectin, and a deposition of tannin and gutta-percha from the juice as insoluble substances.

E. J. R.

Vegetable Phosphatides. Ernst Schulze (Chem. Zeit., 1908, 32, 981—983. Compare this vol., i, 385).—Phosphatides were determined in a number of seeds (without husks), and the following results obtained (percentages in dry matter):

The phosphatide represents only a small percentage of the total phosphorus (in the case of Ricinus, only 1%), and, since the seeds contain very little inorganic phosphorus, it is evident that some other organic phosphorus compounds must be present in much larger quantity than the phosphatides. The substance known as phytin, which yields inositol as a cleavage product, is one of these substances, and is presumably of greater importance to plants than the phosphatides.

N. H. J. M.

Water-soluble Polysaccharides of Barley and Malt.

Horace T. Brown (Bied. Zentr., 1908, 37, 675—676; from Zeitsch. ges. Brauwesen, 1907, 30, 286).—Finely-crushed barley (1 kilo.) was stirred with boiling water (7 litres), cooled to 70°, and, after adding 15 c.c. of malt extract, boiled for a long time. A further amount (250 c.c.) of malt extract was then added, and the whole digested for one hour at 50—55° and again boiled. It was then filtered, the residue well washed with hot water, and the filtrate evaporated to 4 litres under reduced pressure. The resulting liquid, D. 1·060, containing 15% of dry matter, was treated with 80% alcohol; on cooling, white flakes of crude amylan separated. The latter, after being thoroughly washed with 60—70% alcohol, was treated with 500 c.c. of water, and again precipitated with alcohol.

The soluble constituents of barley are as follows: ash, 0·75; proteins, 0·75; sugar, 4·10; starch, 56·20, and amylan, 9·65%. The amylan yields, when hydrolysed with 2·5% oxalic acid, chiefly dextrose along with galactose, mannose, arabinose, and xylose.

Crude amylan from malt dissolves readily in cold water, is strongly dextrorotatory, and has slightly reducing properties. When hydrolysed, it yields dextrose and arabinose.

N. H. J. M.

Fruits of Caulophyllum thalictroides and Cornus sericea.

Edith Stockton and C. G. Eldredge (Chem. News, 1908, 98, 190—191).—The pulp of the fruit of Caulophyllum thalictroides contains lævulose and small quantities of citric, tartaric, and tannic acids. The crushed nuts yield to ether about 3% of oil, calculated on the whole fruits, of which a portion is volatile and the remainder belongs either to the laurin or olein group.

The pulp of the fruit of Cornus sericea contains potassium hydrogen tartrate, potassium hydrogen oxalate, calcium oxalate, gum, tannic, gallic, and malic acids, and a sugar, possibly lævulose. The nuts yield to ether a pale amber-coloured oil, which deposits some solid matter, perhaps palmitin, on standing.

T. A. H.

Constituents of the Rhizome of Imperatoria ostruthium.

Johannes Herzog (Arch. Pharm., 1908, 246, 414—417).—The author has applied the method devised for the preparation of pimpinellin (this vol., i, 905), namely, extraction with benzene and treatment of the concentrated extract with light petroleum, to this rhizome, and has isolated thereby oxypeucedanin, identical with that prepared by Erdmann and by Bothe from the root of Pseuedanum
Constituents of Saffron. Balthasar Pfyl and W. Scheitz (Zeitsch. Nahr. Genussm., 1908, 16, 337—346. Compare Hilger, Abstr., 1900, i, 682).—With the object of devising a process for the detection of inferior saffron (this vol., ii, 997), attempts were made, following lines suggested by the results of previous investigators, to obtain data regarding the properties of the chief constituents of the drug.

The methods suggested by Quadrat (J. pr. Chem., 1852, 56, 68) and Weiss (ibid., 1867, 101, 65), involving the extraction of the saffron, previously freed from fat, &c., by means of ether or light petroleum, with water, and precipitation of the colouring matter (polychroit or crocin) from the aqueous extract by lead acetate or alcohol, do not yield a pure preparation, and the same is true of Kayser’s process, depending on the use of animal charcoal for the extraction of the colouring matter (Abstr., 1885, 59). Only amorphous, impure preparations of crocin could be obtained, and these, on hydrolysis with acids, furnished dextrose (compare Kayser, loc. cit.; Schunck and Marchlewski, Abstr., 1894, i, 340).

Similarly, Kayser’s crocetin (loc. cit.) could only be obtained as an amorphous, red mass, which, however, yielded crystalline salts with metals and certain organic bases (compare Decker, Abstr., 1906, i, 686).

Kayser’s picrocrocin (loc. cit.) could not be prepared, although by using his process for its isolation a small amount of a white, crystalline substance, m. p. 67°, which did not reduce Fehling’s solution, was obtained.

From a chloroformic extract of saffron, three substances were isolated: (1) a colourless, crystalline product, m. p. 280°, which did not reduce Fehling’s solution; (2) a yellow, crystalline substance, m. p. 164°, readily soluble in water or alcohol, which when boiled with acid developed the odour of saffron oil and yielded a reducing sugar, probably levulose, and (3) a crystalline hydrocarbon, m. p. 118° (compare Schüler, Inaug. Diss. Munich, 1899, and Hilger, loc. cit.), apparently similar to the hydrocarbons found in marigold petals, arnica flowers, &c. The second of these products somewhat resembles the picrocrocin described by Kayser.

An alcoholic extract of saffron contains, in addition to colouring matter, a sugar (? levulose) and a glucoside, which, on hydrolysis yields saffron oil and levulose (?). The sugar provisionally regarded as levulose is levorotatory, reduces Fehling’s solution, yields phenylglucosazone, and gives the Seliwanoff reaction (Abstr., 1903, ii, 616).

T. A. H.
Have Manganese Salts, Employed as Stimulants, a Favourable Influence on Vegetation? Sigurd Rhodin (Bied. Zentr., 1908, 37, 667—668; from K. Landtbr. Akad. Handl. Tidskr. Stockholm, 1908, 30—33).—Field experiments with oats grown on peaty soil and with potatoes on rich garden soil. Manganese peroxide (1 kilo. per are), manganese acetate, and benzoate (30 grams per 100 square metres) reduced the yield of oats. In the potato experiment, manganese sulphate (6 kilos. per hectare) was employed. One variety of potatoes showed an increase of 1% of starch on the manganese plot; the total starch was, however, considerably less than without manganese, owing to the smaller yield of tubers.

N. H. J. M.

Manurial Experiments with Nitrogen in 1907. Henrik G. Söderbaum (Bied. Zentr., 1908, 37, 657—659; from K. Landtbr. Akad. Handl. Tidskr. Stockholm, 1908, 104—110).—Oats were grown in sandy soil (25 kilos. per pot), and manured with 0·25, 0·5, and 0·75 gram of nitrogen in different forms, in addition to minerals. The relative manurial effects of the nitrogen compounds varied according to the amounts employed. With the smallest amounts, sodium nitrate gave the highest yields. When 0·5 gram of nitrogen was applied, ammonium sulphate gave the best results; then Polzeniusz’s, Carlson’s, and Frank’s calcium cyanamide preparations; the next best were sodium nitrate and albumin (about equal), and last, calcium nitrate. With the largest amounts of nitrogen, ammonium sulphate was again the best; then Carlson’s and Polzeniusz’s calcium cyanamide; Frank’s cyanamide gave considerably less produce, whilst calcium nitrate was again the least satisfactory.

The total divergence of the results from those of the previous year is attributed to the unusually low temperature in 1907, and the consequent more prolonged vegetative period.

N. H. J. M.

Field Experiments with Ammonium Sulphate. Hermann Bachmann (Bied. Zentr., 1908, 37, 664—665; from Fühlking’s Landw. Zeit., 1907, 530).—Experiments with rye, oats, barley, and mangolds grown on sandy soil and on loam showed that ammonium sulphate produced considerably greater yields than sodium nitrate.

N. H. J. M.

Utilisation of Nitrogen in the Form of Ammonium Nitrate. Theodor Pfeiffer, A. Heppner, and L. Frank (Bied. Zentr., 1908, 37, 663—664; from Mitt. Landw. Inst. K. Univ. Breslau, 1908, 5, 341).—The plants were grown in sand, and manured with ammonium nitrate and sulphate and sodium nitrate respectively. The position of ammonium nitrate as a manure is between sodium nitrate and ammonium sulphate; it may, however, under certain conditions, equal sodium nitrate. Addition of sodium chloride had no appreciable effect: The favourable results obtained by Wagner with sodium chloride in conjunction with ammonium sulphate may have been due to the presence of zeolites in the soil.

Addition of phosphorite along with ammonium nitrate increased the yield and also the amount of nitrogen taken up.

N. H. J. M.
Manurial Trials with Sodium Nitrate and Ammonium Sulphate. H. Clausen (Bied. Zentr., 1908, 37, 585; from Illustr. landw. Zeit., 1907, 27, 842).—Ammonium sulphate proved more effective than sodium nitrate on potatoes, rye, and oats growing on sandy soils. The superiority may be accounted for in several ways; there are indications that the potato plant can directly assimilate ammonia, so that nitrification becomes unnecessary; it is also known that sodium nitrate washes into the sub-soil, and is therefore lost more readily than ammonium sulphate. On the soils in question, Wagner's generalisation, that ammonium sulphate is only 75% as effective as sodium nitrate, clearly does not hold, and the author is of opinion that results similar to his own would commonly be obtained elsewhere.

E. J. R.

Plot Experiments on the New Nitrogenous Manures. Hjalmar von Feilitzen (Bied. Zentr., 1908, 37, 659—663; from Svenska Mosskulturförening. Tidskr., 1908, 91—108).—Calcium nitrate produced higher yields of potatoes and of starch than potassium nitrate both on incompletely humified Sphagnum soil deficient in nitrogen, and on peat soil rich in nitrogen. Similar experiments with oats grown in sandy peat gave similar results.

Experiments in which different varieties of potatoes were grown in sandy soil, and manured respectively with sodium nitrate and two calcium cyanamide preparations, showed that, whilst the plants manured with cyanamide developed somewhat better than those on the nitrate plots, the final yields both of potatoes and starch were highest where nitrate had been supplied.

N. H. J. M.

Analytical Chemistry.

A Shortened Burette. F. Tschaplowitz (Zeitsch. anal. Chem., 1908, 47, 697—698).—The apparatus consists of two 25 c.c. burettes connected at their lower end with a single tap. When the contents of one of the burettes has been run off through the tap, a half-turn of the latter enables the contents of the second burette to be used.

W. P. S.

Combined Wash-bottle and Pipette. J. W. Hogarth (J. Roy. Soc., New South Wales, 1905, 38, 418—420).—A modified wash-bottle by means of which it is possible to deliver an exactly measured volume of liquid.

P. H.

Destruction of Organic Substances. M. Kerbosch (Pharm. Weekblad, 1908, 45, 1210—1213).—The author emphasises the importance of the absence of organic matter in testing for metallic
poisons, and describes a method for destroying it by heating the material with a mixture of sulphuric acid and nitric acid. The method has been applied to milk, peas, meat, and sardines.

A. J. W.

The Use of Nitrous Acid, Nitrites, and Aqua Regia in the Estimation of the Mineral Constituents of Urine. Joseph H. Kastle (Amer. J. Physiol., 1908, 22, 411—422).—The difficulty of incinerating urine completely is well known. If, however, the urea is first got rid of by heating with sodium nitrite, nitrous acid, or aqua regia, incineration is rapidly accomplished, and the inorganic constituents of the ash can be estimated accurately. Each of the three reagents mentioned has special advantages in certain cases.

W. D. H.

Action of Thiosulphate on Permanganate in Alkaline Solution. Heinrich Killiani (Chem. Zeit., 1908, 32, 1018).—Reinige proposed to estimate alkali iodides by titration with permanganate (conversion into iodate), and to estimate the excess by means of thiosulphate, when tetrathionate was supposed to be formed. The author, having received a private communication from Herms, has had the matter investigated, and now states that in the oxidation of thiosulphate in alkaline solution, sulphate is formed. Hence, when using Reinige's process, it must be remembered that 8 mols. of potassium permanganate do not require 24, but only 3, mols. of sodium thiosulphate for decolorisation.

L. de K.

Estimation of [Organic] Sulphur by Carius' Method. Erwin Rupp (Chem. Zeit., 1908, 32, 984).—It is recommended to add barium chloride when oxidising the substance with nitric acid instead of adding it when the oxidation is finished. The barium sulphate thus obtained is of a coarse structure, and consequently readily washed and collected. It must be remembered that it always contains barium nitrate, from which it may be freed by boiling with 150—200 c.c. of water, any large particles being broken up with a glass rod.

L. de K.

Volumetric Estimation of Sulphuric Acid. Thomas Cooksey (J. Roy. Soc., New South Wales, 1907, 41, 215—217).—The author has improved the titration of barium and calcium salts by means of N/10 sulphuric acid and phenolphthalein as indicator, by adding alcohol in such quantity that, after the experiment is finished, the liquid will contain about half its bulk of it. Before titrating, the liquid must, if necessary, be rendered neutral to phenolphthalein with potassium hydroxide. The barium or calcium carbonate is immediately precipitated, and the end reaction becomes very distinct. Sulphates (if necessary, freed from metals other than alkalis) are estimated conveniently by adding to the carefully-neutralised solution a definite amount of barium chloride, the excess of which is then estimated by the above process.

L. de K.
Modification of Hüfner's Method for the Volumetric Estimation of Nitrogen. Victor von Cordier (Zeitsch. anal. Chem., 1908, 47, 682—687).—The apparatus used consists of a cylindrical bulb with a long neck, which is provided with a side-tube, the whole being similar to a Victor Meyer's vapour density apparatus. The bulb has a capacity of about 100 c.c., and is fitted with a stoppered tubulure for introducing the sodium hypobromite solution. A second bulb is also provided, and serves as a reservoir for a further quantity of the solution ; it is attached to the main bulb by a tapped tube, which enters the shoulder of the main bulb, and also at its top by a second tapped tube, which is connected with the neck of the apparatus. About 50 c.c. of Knop's (sodium hypobromite) solution are placed in the main bulb, and about 40 c.c. in the reserve bulb. When required, this portion of the solution is allowed to enter the main bulb by opening both the taps. The use of the apparatus enables a larger quantity of substance to be taken for the estimation, and results of experiments are given showing that the method may be used for the estimation of nitrogen in guanidine picrate, urea nitrate, acetyllurea, ammonium platinichloride, &c.

W. P. S.

E. H.

Presence of Nitrite and Ammonia in Well-water and Its Signification. J. van Eyk (Pharm. Weekblad, 1908, 45, 1162—1165).—At the ordinary temperature, zinc reduces nitrates in aqueous solution to nitrites, and then to ammonia. The author considers that nitrates in well-water may be reduced to nitrites by the zinc employed to galvanise the iron pipes of water pumps.

A. J. W.

Estimation of Phosphorus, Sulphur, and Silicon in Acetylene. Adolf Fraenckel (Chem. Zenthr., 1908, ii, 643—644; from J. Gasbeleuchtung, 1908, 51, 431—435).—The acetylene generated from a known weight of calcium carbide is burnt in a special apparatus, and the products of combustion are drawn through sodium hypobromite solution.

On evaporating to dryness with addition of hydrochloric acid, the silica is obtained; in the filtrate from this, the phosphoric acid is estimated as usual with magnesia mixture. Sulphur is estimated similarly by passing the products of combustion through sodium hypobromite and estimating the sulphuric acid formed as usual.

L. de K.

L. de K.
Estimation of Arsenic in Iron Ores. Marcel Guedras (Chem. Zentr., 1908, ii, 444; from Rev. gener. Chim. pure appl., 1908, 11, 251—253).—One gram of the finely-powdered ore is boiled in a 500 c.c. flask with 150 c.c. of hydrochloric acid and 5 grams of stannous chloride, and the distillate is collected in a graduated 100 c.c. receiver containing 50 c.c. of water. When 40 c.c. have passed over, the distillate is nearly neutralised, a few grams of sodium hydrogen carbonate are added, and the arsenic is titrated as usual with standard iodine.

L. de K.

Apparatus for the Estimation of Carbon in Iron. Max Widemann (Chem. Zentr., 1908, ii, 724—725; from Zeitsch. Chem. Apparatenkunde, 1908, 3, 296).—An improved flask and condensation arrangement. The essential improvement consists in the condensing tube being fitted with 5 bulbs. The gaseous products escape through a side-tube. The tube carrying off the water is fitted with a funnel, in which the water rises in case of sudden pressure, thus preventing the tube from cracking.

L. de K.

Simultaneous Estimation of Carbon, Hydrogen, and Nitrogen, &c., in Organic Compounds by the Method of Simplified Elementary Analysis. Max Dennstedt and F. Hassler (Ber., 1908, 41, 2778—2782).—Oxygen, prepared by heating potassium permanganate, passes through a sulphuric acid tube, through one limb of a T-piece, and through a soda-lime-calcium chloride tube into the bifurcated entry-tube of the combustion apparatus. Through the other limb of the T-piece, oxygen is driven into a weighted rubber bag (15 kilo. per 300 sq. cm.) which acts as a reservoir, by which the current of oxygen during the combustion can be adjusted to a nicety. The combustion tube and absorption apparatus are arranged as usual. To absorb oxygen, a 1 litre Erlenmeyer flask is provided with a two-holed stopper, through which one tube, passing to the bottom of the flask, is connected with an ordinary pressure-adjusting bulb, whilst a capillary T-piece, passing just through the other hole, is connected by one limb with the combustion apparatus, a safety bottle being inserted to prevent back-suction; the other limb of the T-piece, provided with rubber tubing and a pinch-cock, serves as a gas-exit.

The best absorbent of oxygen is cuprous chloride in hydrochloric acid containing pieces of copper gauze. The solution is prepared best from copper sulphate and an excess of hydrochloric acid, as the presence of sulphuric acid increases the rate of absorption of the oxygen. The solution is efficient so long as copper gauze remains undissolved.

The expulsion of air from the whole apparatus requires one to one and a-half hours. At the completion of the combustion the nitrogen is swept into the Erlenmeyer flask for about twenty minutes; after standing overnight, the nitrogen is measured in a Hempel burette. Any nitrogen retained as lead nitrate by the lead peroxide must be extracted by 33% alcohol, the solution evaporated, and the residue of lead nitrate weighed. Sulphur and the halogens are estimated as described in previous communications.
The method is most suitable for the analysis of costly substances, difficult to obtain pure.  

C. S.

Volumetric Estimation of Sodium Hydroxide in the Presence of Sodium Carbonate. A. C. Andersen (J. Pharm. Chim., 1908, 28, 370—371; from Tidskr. Kem. Farm. Terapi, 1908, 11, 161).—This estimation is generally carried out by adding barium chloride, which precipitates the carbonate and leaves the hydroxide; the latter is then titrated with standard acid and phenolphthalein as indicator. But in order to obtain trustworthy results, the author proposes the following slight modification.

After operating in the manner described, another portion of the solution is taken, and sufficient standard acid is added to neutralise the greater part of the hydroxide. The liquid is then heated to boiling, and a slight excess of barium chloride solution is added. When the liquid has cooled (the flask being closed), the titration is continued with phenolphthalein as indicator.

L. de K.

Ready Means of Comparing Sodium Carbonate and Oxalic Acid Solutions. A. Tian (Chem. Zentr., 1908, ii, 636; from Rev. gen. Chim. pure appl., 1908, 11, 208).—The process is based on the fact that oxalic acid liberates the mineral acid from a calcium salt. A measured amount of the oxalic acid solution to be tested is mixed with an excess of calcium chloride, and the turbid liquid titrated with sodium carbonate solution, using helianthin as indicator.

L. de K.

Estimation of Small Amounts of Barium in Rocks. Ralph W. Langley (Amer. J. Sci., 1908, [iv], 26, 123—124).—The author estimates small amounts of barium in rocks by precipitation with sulphuric acid immediately after the separation of silica. It is necessary to re-dissolve the barium sulphate in concentrated sulphuric acid, and to precipitate it with water, in order to free it from ferric and other sulphates. If barium is not removed as sulphate, it is precipitated as phosphate, and introduces an error in the estimation of magnesium.

R. J. C.

Separation of the Metals which are Precipitated by Hydrogen Sulphide. H. Bollenbach (Zeitsch. anal. Chem., 1908, 47, 690—693).—The metals which are precipitated by hydrogen sulphide, and are insoluble in ammonium sulphide, namely, mercury, lead, bismuth, cadmium, and copper, may be separated from each other by the following method. The precipitated sulphides are treated with nitric acid, when all but the mercury goes into solution. Ammonium persulphate is added to the solution, then a considerable excess of ammonia, and the mixture is boiled. Lead and bismuth are precipitated and removed by filtration. The precipitate is dissolved in concentrated hydrochloric acid; one portion of the solution is rendered ammoniacal, then acidified with acetic acid, and tested with potassium dichromate, a yellow precipitate denoting the presence of lead (bismuth chromate is readily soluble in acetic acid).
A second portion of the hydrochloric acid solution is treated with stannous chloride, and sufficient sodium hydroxide is added to redissolve the stannous hydroxide. A black precipitate shows that bismuth is present. The filtrate from the lead and bismuth peroxides is boiled with hydrochloric acid to decompose the ammonium persulphate, and then rendered ammoniacal. A blue coloration denotes the presence of copper. The blue solution is then treated with potassium cyanide and hydrogen sulphide, when a yellow precipitate is obtained if cadmium is present. W. P. S.

Electrolytic Estimation of Thallium and Probable Existence of a New Oxide of this Metal. Gino Gallo and G. Cenni (Atti R. Accad. Lincei, 1908, [v], 17, ii, 276—284).—When a solution of thallous sulphate, slightly acidified with sulphuric acid, is electrolysed, the whole of the thallium is deposited on the anode in the form of an oxide, generally supposed to be the sesquioxide. It was found, however, by Heiberg (Abstr., 1903, ii, 614) that, when the deposit of oxide is heated in order to dry it, its weight at first diminishes and subsequently increases, this increase being supposed by him to be due mainly to the action on the oxide of sulphur dioxide from the gas heating the oven, whilst Werther (J. pr. Chem., 1864, 91, 385) regarded it as being caused by the absorption of carbon dioxide. The authors find that the minimum weight of the deposit is greater than that of the sesquioxide corresponding with the amount of thallium employed, their results indicating that the sesquioxide is converted into an oxide of the composition \( \text{Tl}_3\text{O}_5 \). The oxide \( \text{Tl}_2\text{O}_3 \) is probably transformed partly into \( \text{TlO}_2 \), which, with \( \text{Tl}_2\text{O}_3 \), gives the compound \( \text{Tl}_3\text{O}_5 \). The formation of such an oxide is not surprising, considering the position of thallium between mercury and lead in the periodic system, and also the existence of mercury peroxide (compare Antropoff, Zeitsch. Elektrochem., 1906, 12, 585; Pellini, Gazetta, 1908, 38, i, 71).

The best procedure for the quantitative, anodic deposition of thallium as oxide is to dissolve thallous sulphate in about 100 c.c. of water in a Classen capsule, the solution being acidified by the addition of about 0.1 gram of oxalic acid, and electrolysed at the ordinary temperature with a platinum disk rotating at 800 revs. per minute as negative electrode; the voltage should be 3—4, and the current density, 0.15—0.20 ampere. The end of the electrolysis is ascertained by adding a little water so as to raise the level of the liquid in the capsule; no deposit should appear on the clean platinum surface thus freshly brought into contact with the solution. The weight of the deposit, after drying at 160—200°, corresponds with the formula \( \text{Tl}_3\text{O}_5 \), and, when dissolved in hydrochloric acid, the oxide causes evolution of chlorine and forms the chloride, \( \text{TiCl}_3,3\text{TiCl} \). The oxide hence decomposes according to the equation:

\[ 8\text{Tl}_3\text{O}_5 = 3\text{Tl}_2\text{O}_3 + 9\text{Ti}_2\text{O} + 11\text{O}_2, \]

and the authors regard it as having the structure

\[ \text{O}^\cdot\text{Ti} \cdot \text{O} \cdot \text{Ti}^\cdot \text{O} \cdot \text{Ti} \cdot \text{O}. \]

T. H. P.
Analysis of a Mineral containing Copper, Bismuth, Lead, Silver, Calcium, Iron, and Quartz. August Chwala and V. Machi (Chem. Zentr. 1908, ii, 261; from Mon. Sci., 1908, [iv], 22, 372).—The mineral is decomposed by means of nitric acid and potassium chlorate, and a solution of ammonium nitrate is added to keep lead and calcium sulphates in solution. The siliceous matter is then collected and washed, first with a hot acid and then with a hot ammoniacal solution of ammonium nitrate. After removing any silver from the filtrate by means of hydrochloric acid, sulphuric acid is added, and then excess of ammonia, which precipitates the iron only; this is washed first with an acid and then with an ammoniacal solution of ammonium nitrate. The bismuth is then precipitated with ammonium carbonate, and, finally, the copper and lead are separated as usual.

L. De K.

Solubility of Rare Earth Oxalates in Solutions containing Uranyl Salts. Otto Hauser (Zeitsch. anal. Chem., 1908, 47, 677—680).—It is pointed out that uranyl salts have a considerable solvent action on cerium and lanthanum oxalates, and, unless a considerable excess of oxalic acid is added, the results obtained in the usual method of precipitating these earths as oxalates are untrustworthy, if uranyl salts are present.

W. P. S.

Separation of the Metals of the Ammonium Sulphide Group. Erich Ebler (Zeitsch. anal. Chem., 1908, 47, 665—677).—The following process of separating the metals precipitated by ammonium sulphide is recommended. The precipitate, consisting of iron, manganese, nickel, cobalt, and zinc sulphides, and aluminium and chromium hydroxides, is boiled with hydrochloric acid until all the hydrogen sulphide has been expelled, then oxidised with nitric acid, and treated with hydrogen peroxide and sodium hydroxide. The precipitate, which contains the iron, manganese, nickel, and cobalt, is separated by filtration, dissolved in hydrochloric acid, hydrogen peroxide is added, and the iron and manganese are precipitated with ammonia; these two metals are separated from their hydrochloric acid solution by the addition of ammonium chloride, hydroxylamine hydrochloride, and ammonia, the iron being precipitated, whilst the manganese remains in solution. The nickel and cobalt are separated by adding dicyanodiamide and potassium hydroxide to the filtrate containing them; the nickel is precipitated as a crystalline compound. The filtrate containing the aluminium, chromium, and zinc is boiled, and ammonium chloride is added repeatedly until ammonia ceases to be given off; the aluminium hydroxide thus precipitated is removed by filtration, and the filtrate is treated with sulphurous acid after acidifying with hydrochloric acid. The addition of ammonia to the hot solution precipitates the chromium, leaving the zinc in solution.

W. P. S.

Estimation of Iron, Alumina, and Phosphoric Acid in Presence of Each Other. Thomas Cooksey (J. Roy. Soc., New South Wales, 1907, 41, 163—171).—The acid solution is mixed with a definite
amount of a standard solution of sodium dihydrogen phosphate, and potassium hydroxide solution is added until the liquid is neutral to methyl-orange. The whole is diluted to 80—90 c.c., and heated on the water-bath until the precipitate has settled. To the filtrate is added an excess of calcium chloride, the liquid is acidified slightly with N/10 acid, boiled to expel carbon dioxide, and the free phosphoric acid is titrated with N/10 potassium hydroxide, using phenolphthalein as indicator, as soon as the liquid is neutral to methyl-orange; 1 c.c. = 0·00355 gram of \( \text{P}_2\text{O}_5 \).

The iron oxide is determined iodometrically, and calculated to ferric phosphate. This deducted from the weight of the first precipitate gives the aluminium phosphate, which is then calculated to alumina. From the total phosphoric acid found, is then deducted the amount purposely added.

**Separation of Iron from Nickel and Cobalt by Lead Oxide.**

T. H. Laby (J. Roy. Soc., New South Wales, 1904, 37, 157).—After trying the separation by means of ammonium hydroxide and chloride, ammonium carbonate, the basic acetate process, the phosphate method, the electrolytical separation, and the ether extraction process, the author finally calls attention to a process given by Field (Chem. News, 1859, 1, 5), which he finds is also suitable for the separation of iron from cobalt.

In this process the iron is precipitated as hydroxide by evaporating the nitrate solution with excess of lead oxide; the lead is separated readily from the filtrate with sulphuric acid. The nickel or cobalt is then estimated electrolytically in ammoniacal solution.

**Detection of Cobalt in the Presence of Large Quantities of Nickel.**

M. Emmanuel Pozzi-Escot (Ann. Chim. anal., 1908, 13, 390—391).—Supposing the amount of nickel to be about 1000 times that of the cobalt, the solution containing about 10 grams of the nitrates is concentrated to 25—50 c.c. and mixed while hot with 50 grams of ammonium molybdate dissolved in a little boiling water. When cold, the liquid is filtered from the nickel precipitate, and the rose colour of the cobalt becomes visible. On boiling with excess of sodium hydroxide and a little hydrogen peroxide, the cobalt is obtained as a brown oxide, which may then be identified by means of the borax bead.

**Approximate Colorimetric Estimation of Cobalt and Nickel in the Presence of Each Other.**

R. W. Challinor (J. Roy. Soc., New South Wales, 1905, 38, 406—417).—The two metals are estimated jointly by electrolysis, and then dissolved in dilute nitric acid (1 : 1). After evaporating nearly to dryness, the mass is dissolved in water and diluted to a known volume. If the liquid is green, more than 76% of nickel is present; an aliquot portion of the liquid, containing 0·04—0·05 gram of the mixed metals, is taken, and a standard solution of cobalt is run in until the colour (after diluting to the 50 c.c. mark) is equal to that of a standard solution containing the nearest weight of the mixed metals. If, however, the solution is pink, showing
the presence of more than 24% of cobalt, standard nickel is run in, any excess of which may be again checked with cobalt.

After allowing for nickel added, the amount of nickel in the mixture is readily calculated.

L. DE K.

Iodometric Estimation of Chromic and Vanadic Acids in the Presence of Each Other. GRAHAM EDGAR (Amer. J. Sci., 1908, [iv], 26, 333—336).—The mixed acids (about 0·2 gram) are boiled with 15 c.c. of hydrochloric acid and 2 grams of potassium bromide in a Voit flask, a slow current of hydrogen is passed, and the bromine evolved, owing to the reduction of $2\text{CrO}_4$ to $\text{Cr}_2\text{O}_3$ and $\text{V}_2\text{O}_5$ to $\text{V}_2\text{O}_4$, is absorbed in an alkaline solution of potassium iodide contained in a Drexel bottle connected with a Will and Varrentrap trap, also containing the same solution. After the operation is over, the potassium iodide solution is acidified with hydrochloric acid, and the iodine set free titrated as usual. The Drexel bottle is then filled with fresh potassium-iodide solution.

To the contents of the Voit flask are now added 2 grams of potassium iodide, 15 c.c. of hydrochloric acid, and 3 c.c. of syrupy phosphoric acid, and the distillation is repeated as before in a current of hydrogen. The hydriodic acid acts on the $\text{V}_2\text{O}_4$, reducing this to $\text{V}_2\text{O}_3$ with liberation of iodine, which is absorbed in the Drexel bottle and titrated as usual. The second titration therefore gives the vanadic acid only, and the difference between the first and second gives the necessary data for the calculation of the chromic acid.

L. DE K.

Tin. DAVID B. DOTT (Pharm. J., 1908, [iv], 27, 486).—Contrary to general belief, metastannic acid, formed by the action of nitric acid on tin, is soluble in hydrochloric acid. All quantitative processes based on the separation of silica from tin by evaporation to dryness are untrustworthy, as a large proportion of the tin volatilises as chloride. The author proposes the following method for the estimation of tin in the presence of antimony.

The solution is divided into two equal portions. In one of these, both metals are precipitated with hydrogen sulphide, and the precipitate is then converted in the usual manner into a mixture of tin and antimony dioxides. The other portion is saturated with oxalic acid, heated, and treated with hydrogen sulphide, which now precipitates the antimony only; this is then converted into dioxide and deducted from the joint weight.

Low's modification of Pearce's method for the estimation of tin in ores, by fusing with sodium hydroxide, dissolving in hydrochloric acid, reducing by boiling with iron wire, and, after filtering into a flask filled with carbon dioxide, rapidly titrating with standard iodine, gives good results.

L. DE K.

Analysis of Oxidised Antimony and Lead Sulphide Compounds. FELIX JACOBSSON (Chem. Zeit., 1908, 32, 984—985).—The article is mainly devoted to the assay of commercial Sulphur antimonii auratum (this vol., ii, 540).
The process is also applicable to lead sulphide. For the estimation of free sulphur, the use of boiling chloroform is recommended.

L. de K.

Volumetric Estimation of Bismuth. Pierre Balavoine (Zeitsch. anal. Chem., 1908, 47, 681).—The author mentions that previous to the publication of the results of Moser’s investigation (Abstr., 1907, ii, 433) on the volumetric estimation of bismuth, he had recorded the results of experiments showing that the method was untrustworthy.

W. P. S.

Analysis of Organic Mixtures with the Aid of the Refractometer. Ernst E. Sundwick (Pharm. Zentr.-h., 1908, 49, 783—787).—Some remarks on the process of Beythien and Hennicke (this vol., ii, 72).

The author’s own process is based on the following equations: (1) \( V:V_1 = C_1 - B\); \( C - B\), in which \( V \) and \( V_1 \) represent two volumes containing the same amount of dissolved matter, \( C \) the refraction of the joint solution, and \( B \) the refraction of the solvent (water, alcohol, chloroform, acetone, toluene, &c.); (2) \( V(C - B) = \text{constant} \), and (3) \( P(C - B)/d = \text{constant} \).

L. de K.

Methyl Alcohol and its Impurities. Franz Friedrichs (Chem. Zeit., 1908, 32, 890-891).—In examining methyl alcohol for impurities, the carbylamine test for chloroform should not be omitted, in view of the fact that methyl alcohol is sometimes treated with bleaching powder in order to remove acetone, which is thereby converted into chloroform.

P. H.

Gravimetric Alcoholometry. Blondeau (Bull. Assoc. Chim. Sucr. Dist., 1908, 26, 148—160).—Tables are given showing the weight of alcohol per hectolitre of mixtures of alcohol and water. The values are given for each reading of the Gay-Lussac alcoholometer between 1 and 100 at temperatures from 0° to 30° (compare Abstr., 1908, ii, 738).

W. P. S.

New Differential Reactions of the Naphthols. Volcy-Boucher (Ann. Chim. anal., 1908, 13, 335—338).—The following reagents are used: Alcohol of 95° (French), a 10% solution of copper sulphate, and a 10% solution of potassium cyanide prepared just before use.

Identification of the Naphthols.—0·5 Gram of the substance is placed in a test-tube, and dissolved in the smallest possible quantity of alcohol, added drop by drop. Two c.c. of the copper solution are added, and, after thorough shaking, 4 c.c. of the cyanide. With \( \alpha \)-naphthol an abundant, violet-red precipitate is obtained; \( \beta \)-naphthol yields a yellow precipitate. If now just sufficient alcohol is added to dissolve the precipitate, a rose-coloured liquid showing a violet reflection will be obtained with the \( \alpha \)-compound, but a golden-yellow solution in the case of \( \beta \)-naphthol.

Identification of the Camphorated Naphthols.—A thread of the
substance is placed in a test-tube, and 2 c.c. of copper solution are added. The substance, which floats on the surface, is dissolved by cautious addition of alcohol, and 4 c.c. of the cyanide are then added. The result is the same as with the ordinary naphthols.

The same process serves for the detection of small proportions of \( \alpha \)-naphthol in the \( \beta \)-compound. Benzonaphthol does not give the reaction.

L. de K.

Estimation of Lactose by Ammoniacal Copper Salt Solutions. Yoshitaka Shimizu (Biochem. Zeitsh., 1908, 13, 243—261).—Lactose can be estimated by means of the Kumagawa-Suto modification of Pavy’s method, if it is first hydrolysed into dextrose and galactose. For the latter purpose, 10% sulphuric acid, or 5% hydrochloric acid, are suitable, and inversion is complete within one hour if 100 c.c. of acid is used for 0.25 to 1 gram of the sugar. The method is applicable to the estimation of sugar in milk. S. B. S.

Precipitation of \( \text{\ae} \)-levulose by Basic Lead Acetate. H. C. Prinsen-Geerligs (Zeitsch. Ver. deut. Zuckerind., 1908, 932—936).—The results of the experiments recorded show that, whilst basic lead acetate does not precipitate levulose from its solution when the latter contains nothing but the sugar, an appreciable quantity of the sugar is precipitated if other substances which yield insoluble lead compounds are also present. As all syrups and crude sugars give such solutions, these, when clarified with basic lead acetate, furnish filtrates containing less levulose than the original solution. The reducing sugar precipitated is shown to be actually levulose. W. P. S.

Detection of Formic Acid in Honey. Th. Merl (Zeitsch. Nahr. Genussm., 1908, 16, 385—389).—Formic acid is best detected in honey by heating the sodium formate, obtained on evaporating the neutralised distillate of the honey, with concentrated sulphuric acid. The carbon monoxide produced is collected over potassium hydroxide solution, and, if its volume is measured, the quantity of formic acid present may be calculated. Lactic acid, which may also be present in the distillate, yields carbon monoxide on treatment with sulphuric acid, and a portion of the distillate should therefore be oxidised with permanganate and the resulting oxalic acid estimated. The quantity of carbon monoxide due to the lactic acid is then deducted from the total volume of gas found. The calomel formed by the action of formic acid on mercuric chloride may also be employed as a measure of the amount of formic acid present, but it is pointed out that other substances present in honey distillates reduce mercuric chloride.

W. P. S.

Acidification and Distillation of Fatty Acids; Distilled Oleic Acid. Hugo Dubovitz (Chem. Zentr., 1908, ii, 545; from Seifensieder Zeit., 1908, 25, 728—729).—The acidification of the fatty acids yields, according to Benedikt, sulphostearic acid, which on boiling with water yields hydroxystearic acid. The author, however, obtained about twice the
quantity of hydroxystearic acid than would be expected, and has therefore altered Benedict's formula for sulphostearic acid into

$$\text{SO}_4\text{C}_{17}\text{H}_{34}\text{CO}_2\text{H}_2.$$  

The presence of small quantities of neutral fat in commercial oleic acid ('distillation olein') is difficult to confirm, owing to the possible presence of anhydrides and lactones. Owing to the presence of volatile fatty acids, the estimation of water in the oleic acid should be effected in a vacuum over calcium chloride.  

L. de K.

Estimation of \(\beta\)-Hydroxybutyric Acid in Urine. Philip A. Shaffer (J. Biol. Chem., 1908, 5, 211—224).—Previous methods for the estimation of this acid are criticised. The method proposed is to distil with sulphuric acid and potassium dichromate, when under suitable conditions, the acid is converted quantitatively into acetone, which is then determined by standard iodine and thiosulphate solutions. A number of precautions, especially in estimations in urine, have to be taken.

W. D. H.

Detection and Estimation of \(\beta\)-Hydroxybutyric Acid in Urine. Otis F. Black (J. Biol. Chem., 1908, 5, 207—210).—Acetoacetic acid is recognised by the red colour produced by ferric chloride. If \(\beta\)-hydroxybutyric acid is tested in the same way in the presence of hydrogen peroxide, the same colour reaction is obtained. In applying the test to urine, evaporation at a gentle heat gets rid of acetooacetic acid; the residue is acidified with hydrochloric acid, and made into a paste with plaster of Paris. This is broken up and extracted with ether, the ether is evaporated, and the test applied to the residue. For quantitative purposes, the residue is extracted with water and examined with a polarimeter.

W. D. H.

Natural and Added Free Tartaric Acid in Natural Wines. H. Astruc and J. Mahoux (Bull. Soc. chim., 1908, [iv], 3, 840—845; Ann. Chim. Anal., 1908, 13, 307—315).—The method of estimating the total tartaric acid and the total potassium in a wine, and deducing therefrom the amount of free tartaric acid, gives too low a value for the latter, since the amount of potassium combined with other acids is neglected. In this manner, excessive (added) quantities of free tartaric acid in natural wines are overlooked.

The authors have estimated the total tartaric acid and potassium by the official methods, and the added tartaric acid and total potassium by other methods, in three natural wines prepared by the authors, both when untreated and after addition of variable known quantities of tartaric acid and potassium, and draw the following conclusions from their results. The official methods are liable to large errors in opposite directions, the other methods (Pasteur, Reboul, Magnier de la Source, &c.) are more trustworthy, and should therefore be preferred; it is also more accurate to ignore the estimation of total potassium, and to evaporate in the presence of potassium bromide, in order to estimate free tartaric acid. It is impossible to distinguish natural from added tartaric acid in potable wines.
The authors' results contradict the statement that natural wines from ripe grapes are necessarily always free from tartaric acid.

E. H.

Method of Estimating Succinic Acid in Fermented Liquids containing Other Fixed and Volatile Acids. M. Emmanuel Pozzi-Escot (Compt. rend., 1908, 147, 600—601; Bull. Assoc. chim. Sucr. Dist., 1908, 26, 185—186 *).—The following method is stated to be trustworthy for the separation and estimation of succinic acid in solutions containing colouring matters, tannin, proteins, and fixed and volatile acids. A portion of the solution is treated with a small quantity of gelatin, neutralised with ammonia, and then rendered distinctly acid with acetic acid. Barium chloride is next added, and the precipitate, consisting of proteins, tannin, barium oxalate, barium sulphate, &c., is removed by filtration. The filtrate is boiled and treated with a considerable excess of lead acetate, which precipitates any remaining protein and tannin, and phosphoric, tartaric, and citric acids. The precipitate is collected on a filter and washed with very dilute acetic acid. The filtrate is treated with hydrogen sulphide to remove the excess of lead, and the solution is then acidified with sulphuric acid, boiled, and the malic acid is oxidised by the addition of an excess of potassium permanganate. This excess is decomposed by means of potassium hydrogen sulphite, and the sulphuric acid is removed by treatment with barium chloride. The solution is then concentrated, rendered slightly ammoniacal, and the succinic acid is precipitated by the addition of an alcoholic solution of barium bromide, a quantity of alcohol equal to three times the volume of the total solution being also added. The barium succinate is collected on a filter, washed with 60% alcohol, and ignited. The amount of succinic acid is calculated from the weight of barium carbonate obtained (compare this vol., ii, 904).

W. P. S.

Naphtharesorcinol as a Reagent for Certain Aldehyde and Keto-acids. John A. Mandel and Carl Neuberg (Biochem. Zeitsch., 1908, 13, 148—151).—The reaction described by B. Tollens for glycuronic acid (heating with naphtharesorcinol and hydrochloric acid, and subsequent extraction with ether) is applicable to several other substances, especially those containing certain combinations of carboxyl and carbonyl groups in the molecule. Also, certain more complex substances, such as glucothionic acid, ovomucoid, chondroitinsulphuric acid, and various nucleo-proteins, give the reaction.

S. B. S.

Separation of Benzoic Acid and Cinnamic Acid. Anne W. K. de Jong (Pharm. Weekblad, 1908, 45, 1115—1116).—Scheringa's process (separation of the bulk of the cinnamic acid as calcium cinnamate and oxidation of the remainder with permanganate: Abstr., 1907, ii, 823) is, in the author's opinion, unsuitable for quantitative purposes, owing to the formation of benzoic acid.

L. de K.

J. J. S.

Humic Acid. A. J. van Schermbeck (J. pr. Chem., 1908, [ii], 78, 285—288. Compare this vol., ii, 743).—A reply to Tacke and Sückting (preceding abstract), and a further criticism of these authors' methods.

G. Y.

Colour Reactions of Sesamé Oil with (a) Aromatic Aldehydes and (b) Various Sugars. The Similar Reactions with Biliary Acids. C. Fleig (Bull. Soc. chim., 1908, [iv], 3, 984—991, 992—999).—The suggestion has been made (Mylius, Abstr., 1887, 1149) and denied (Ville, Abstr., 1907, ii, 913) that the red or violet colorations formed in the Pettenkofer test for biliary acids, and in the Camoin-Baudouin test for sesamé oil, depend on the formation of furfuraldehyde by the action of the sulphuric or hydrochloric acid on the sucrose used. The author has therefore tried to obtain definite data on this point by using (1) various aromatic aldehydes and (2) polyhydric alcohols and sugars in place of sucrose, and the results, on the whole, support Mylius' contention. It is suggested that the differences in colour produced in using furfuraldehyde instead of sucrose, as noted by Ville, may be due to secondary influences exerted by other hydrolytic products formed when sucrose is used.

Of the thirteen aldehydes tried, p-hydroxybenzaldehyde, anisaldehyde, protocatechualdehyde, vanillin, piperonal, and cinnamaldehyde give colours as intense as those yielded by furfuraldehyde, whilst benzaldehyde, salicylaldehyde, o-nitrobenzaldehyde, and p-dimethylaminobenzaldehyde yield less intense tints, and m- and p-nitrobenzaldehyde and cinnamaldehyde are still less satisfactory.

The polyhydric alcohols and sugars tried as substitutes for sucrose in the Camoin-Baudouin reaction fall into the following five groups, in order of increasing intensity of colour produced: (a) lævulose, invert sugar, sucrose, sorbose; (b) raffinose; (c) xylose, arabinose; (d) galactose, mannose, mannitol, dextrose; (e) isodulcitol, erythritol, sorbitol, dulcitol, lactose, maltose, glycerol. All the sugars in this list, except arabinose, were also tried in the Pettenkofer test, and gave similar results.

In both tests the production of colour is expedited by warming the mixture slightly; hydrochloric acid may be used in place of sulphuric acid or vice versa, but in some cases the former acid is advantageous. In the tests for sesamé oil, an alcoholic extract of the oil may be used in place of the oil itself. Full details are given in the two papers as to the exact methods employed in making the tests. The second paper concludes with a summary of the literature dealing with the constituent of sesamé oil to which the production of the colour is due, and the conclusion is drawn that this coloration may be due to the presence of a number of different substances.

T. A. H.

Formation of Formaldehyde in Solutions of Sugar. A. Alexander Ramsay (J. Roy. Soc., New South Wales, 1907, 41, 172—175).—Attention is called to the fact, noticed amongst others by the
author, that small quantities of formaldehyde are formed during the heating or distillation of saccharine liquids (jams, for instance); thus upsetting the value of some tests recommended for the detection of added formalin.

L. DE K.

Identification of Thujone in Liqueurs. L. Duparc and A. Monnier (Ann. chim. anal., 1908, 13, 378—382).—The liqueur is submitted to distillation, and 10 c.c. of the distillate (which should be of 60° alcoholic strength) is mixed with 2 c.c. of 10% zinc sulphate, 0·5 c.c. of 10% sodium nitroprusside, and then with 4 c.c. of 5% sodium hydroxide free from carbonate. After the lapse of one minute, 2 to 3 c.c. of glacial acetic acid are added, when, after a few minutes, a very characteristic, dark red precipitate forms if thujone is present.

The author has examined altogether fifty-four different essences (2 parts dissolved in 1000 parts of alcohol), and, with the exception of thujone, they yielded white or yellow precipitates; those which contained citral, however, gave an orange-red deposit.

L. DE K.

Analysis of Scammony Resins. P. Guigues (Bull. Soc. chim., 1908, [iv], 3, 872—878).—The ether assay of scammony resin advocated by the Codex Medicamentarius is unsound, since (1) the resin of jalap is partly soluble in ether, whilst some resins from scammony are incompletely soluble in this solvent; (2) it permits the substitution of fusiform jalap resin, soluble in ether, for the true scammony resin; (3) it prevents the recognition of foreign resins, particularly colophony, soluble in ether; and (4) it is subject to numerous errors, and does not give constant results.

The solubility of scammony resin is not appreciably altered by boiling with water or with 10% hydrochloric acid for several hours. Assay of the resin by turpentine instead of ether is no more successful. The author proposes to detect adulteration by determination of the rotatory power. The following are the values obtained for the optical activities of resins: Commercial Tampico jalap, −34°20'; true Orizaba jalap, −24°45'; officinal jalap, −36°; officinal turbithe, −30°10' to 31°35'; ordinary colophony, +6° to +7°; sandarac from the Arabic bazaar, +46°20'; pure sandarac, +31° to +34°; recent mastic, +29°30'; second quality mastic, +21°50'; guaiacum, −17°. For scammony, the author obtained −24°30' as a maximum from the resin extracted from the gum-resin, and −18°30' to −23°30' for resins extracted from the roots. The rotatory power is independent of the solubility in ether. These values show that only the Orizaba jalap (fusiform) resin and guaiacum resin can be used as adulterants. Since only the scammony resins extracted from the gum resin, which are at least twice as expensive as that extracted from the root, have rotatory powers as high as −24°30', a resin having αp higher than −23°30' is most probably fusiform jalap resin. Guaiacum resin should be readily detected by its chemical characteristics.

E. H.

Detection of Arbutin in Plants. Mlle. A. Fichtenholz (J. Pharm. Chim., 1908, [vi], 27, 255—262).—In applying Bourquelot's method (Abstr., 1902, ii, 55) to the detection of glucosides in plants,
Volumetric Estimation of Potassium Ferrocyanide. H. Boltenbach (Zeitsch. anal. Chem., 1908, 47, 687—690).—The following modification of de Haën's process was found to give trustworthy results. The potassium ferrocyanide solution is acidified with sulphuric acid, and an excess of \(N/10\) permanganate solution is added. After the addition of a few drops of ferric sulphate solution, the excess of permanganate is titrated with \(N/10\) ferrocyanide solution. Each drop of the latter added produces a greenish-blue precipitate, which disappears on shaking, as long as any permanganate remains.

W. P. S.

Detection and Estimation of Hexamethyleneamine in Pharmaceutical Mixtures. William A. Puckner and W. S. Hilpert (J. Amer. Chem. Soc., 1908, 30, 1471—1474).—The process is based on the fact that hexamethyleneamine does not suffer decomposition on boiling with aqueous potassium hydroxide, but that it is converted into formaldehyde and ammonium sulphate on boiling with dilute sulphuric acid. The ammonia formed is then readily estimated, any ammonia pre-existing in the sample under examination being removed by the preliminary alkaline treatment.

The reactions with mercuric chloride and with bromine are also useful in the identification of hexamethyleneamine. Advantage may also be taken of its solubility in chloroform.

L. De K.

Estimation of the Total Alkaloids in Cinchona Barks. N. H. Cohen (Pharm. Weekblad, 1908, 45, 1089—1098).—A modification of Florence's method (Abstr., 1907, ii, 317). Five grams of the very fine powder are placed in a small corked flask, 125 grams of ether and 5 c.c. of 15% sodium hydroxide are added, and the whole is weighed. After shaking vigorously every five minutes for an hour, the flask is fitted to a vertical condenser, and the contents are boiled for half an hour. When cold, ether is added to restore the original weight, 5 c.c. of water are introduced, and, after thorough shaking, the ether is transferred to a 250 c.c. flask. Twenty c.c. of lime water are added, the flask is closed, preferably with the same cork, and the whole thoroughly shaken. One hundred c.c. of the ether are now drawn through a plug of cottonwool into a weighed 200 c.c. flask, the ether is distilled off, and the residual alkaloids dried for one and a-half hours at 100° and weighed. The weight \( \times 25 \) percentage of alkaloids, about 0.5 of which consists of impurities. These may be estimated by dissolving the alkaloids in 10 c.c. of 2% sulphuric acid and shaking the solution with ether, which is then evaporated in a weighed flask.

T. A. H.

it is necessary to allow the emulsin to act on the plant extract during several days, as the action of the ferment is frequently slow, owing to the presence of tannic or gallic acids, which retard its activity. In the case of such glucosides as arbutin, which has a high laverotation, it is advantageous to defecate the plant extract with lead acetate before adding emulsin. Bearberry leaves contain at least 1.66% of arbutin.

L. De K.
Florence's estimation of the quinine by means of \( N/10 \) ethereal oxalic acid cannot be recommended.

L. de K.

The Quantitative Relations of the Thalleoquinine Reactions. Jos. Vondrasek (Chem. Zentr., 1908, ii, 833—834; from Pharm. Post, 1908, 41, 605—607).—The author recommends that the test for quinine should be carried out as follows: 0.01 gram of the quinine salt is dissolved in a mixture of 1 c.c. of \( N \) hydrochloric acid and 2 c.c. of \( N/10 \) potassium bromate, and boiled until the liquid turns orangegreen. When cold, 1—2 c.c. of ammonia are added, and a dark green solution is obtained. Quinidine also gives the test. In this reaction, three atoms of chlorine are taken up by 1 mol of quinine. The test may be also carried out in the cold, when addition of ammonia will give a dark green precipitate and a dark green liquid. On adding alcohol, a solution is obtained which is suitable for the colorimetric estimation of quinine.

Quinine and quinidine may be distinguished from cinchonine and cinchonidine by heating the aqueous solutions with excess of potassium bromate, which yields a blue liquid. The colour is destroyed on adding acid.

L. de K.

Assay of Coca. Anne W. K. de Jong (Chem. Weekblad, 1908, 5, 645—647).—A reply to M. Greshoff (this vol., ii, 441). The author gives experimental results in support of the contention that Greshoff’s method of estimating coca is untrustworthy, and attributes this to decomposition caused by heating the alkaloid salts in aqueous solution (compare Abstr., 1905, ii, 778; this vol., ii, 440).

A. J. W.

L. de K.

Detection of Vegetable Poisons in Decomposed Animal Bodies. Theodor Panzer (Zeitsch. anal. Chem., 1908, 47, 572—590).—Corpses which have undergone a considerable amount of decomposition may contain substances which yield general reactions similar to those given by the alkaloids. These substances, which are chiefly found in the brain, and to a less extent in the liver and kidneys, do not give the characteristic reactions of the separate alkaloids. If a residue is obtained from the ethereal extract of the alkaline solution obtained in the usual way (Stas-Otto method) from the organs under examination, which residue gives general alkaloïdal reactions, the solution of the residue should be rendered acid with hydrochloric acid and extracted with ether; this treatment removes the substances, and the aqueous solution is then examined for alkaloids. If possible, it is preferable not to mix the brains with the other organs of the body under examination.

W. P. S.

process depends upon the estimation of the amount of sugar formed by the hydrolysis of the glucoside soluble in chloroform, which the authors have shown occurs in saffron (this vol., ii, 979). Saffron is dried, powdered, and re-dried, and 5 grams of the preparation extracted in a Soxhlet apparatus with light petroleum and, after drying, re-extracted with dry chloroform. The solvent is evaporated from the chloroformic extract, and the residue dissolved as far as possible in acetone. The latter is evaporated, and the glucoside in the residue hydrolysed by adding 5 c.c. of $N$-hydrochloric acid and heating during fifteen minutes, water being added as required to bring the total amount of liquid up to 25 c.c. The filtrate from this is neutralised with $N$-alkali, and the sugar estimated by Allihn's method.

The best quality of commercial saffron, consisting only of the stigmas of the saffron crocus, yields in this way 0·1996 to 0·2090 gram of metallic copper, and samples yielding less than this may be regarded as having an unduly large proportion of styles included, or as containing constituents foreign to the saffron crocus. The quantity of adulterant present is not directly proportional to the diminution in the amount of copper obtained, since the latter is, in part, dependent on the concentration of sugar solution used, and a table is supplied in the original from which, by a method of interpolation, the quantity of "real saffron" present in a sample can be calculated from determinations made by the above process. Trials with the usual adulterants of saffron, namely, saffron crocus styles, logwood, red poppy petals, red peony petals, honey, marigold petals, safflower, Cape saffron, and Spanish thistle flowers, show that each of these products, when subjected to this process, yields practically no reducing substance, and that with turmeric and red sandalwood very much smaller quantities of copper are obtained than with real saffron.

Detection of Proteins by means of Formaldehyde. Leo von Liebermann (Zeitsch. Nahr. Genussm., 1908, 16, 231).—Five c.c. of the solution to be tested are treated with one drop of 40% formaldehyde solution and one drop of very dilute ferric chloride solution. The mixture is then allowed to flow over the surface of 5 c.c. of concentrated sulphuric acid. If protein (albumin or albumose) is present in the solution, a violet ring is observed at the junction of the two liquids.

W. P. S.

A New Reaction for Bile Acids. Adolf Jolles (Zeitsch. physiol. Chem., 1908, 57, 30—34; Ber., 1908, 41, 2766).—If a few drops of a 5% solution of rhamnose are warmed with a similar amount of a 0·1% solution of taurocholate or glycocolate, and a few drops of concentrated hydrochloric or sulphuric acid, a momentary red coloration is obtained, which passes in a short time into a green fluorescence. This test is given also by cholic acid, but not by glycine or taurine. The delicacy of the test is very considerable. In employing it to detect bile acids in urine, the fluid is first mixed with a solution of caseinogen, and the latter is precipitated by careful
addition of sulphuric acid and filtered off. The precipitate is
digested with absolute alcohol at room temperature for an hour,
filtered, and the reaction tried with the filtrate. Cholesterol, albumin,
urea, carbohydrates, higher hydrocarbons, and acids of the fatty and
benzene series do not give the test.

W. D. H.

A Colour Reaction of Bile Acids with Vanillin and Sulphuric
Acid. Katsuji Inouye and Hiizu Ito (Zeitsch. physiol. Chem., 1908,
57, 313–314).—If vanillin is added to an aqueous solution of bile
acids, and then concentrated sulphuric acid, a red ring appears at the
junction of the two liquids; on shaking up the mixture, it becomes red,
then brown or yellow, and finally violet. On diluting this with glacial
acetic acid, a wide absorption band at D, reaching to C on one side
and E on the other, is seen. Tables are given showing the delicacy of
the test with cholic, glycocholic, and taurocholic acids. W. D. H.

The Lecithin-content of Milk. Joseph Nerking and E. Haensel
(Biochem. Zeitsch., 1908, 13, 348–353).—For estimation of lecithin,
100 c.c. of milk were precipitated with 200 c.c. of alcohol. The
precipitate was extracted with chloroform in a Soxhlet apparatus.
The alcoholic filtrate was evaporated at 50–60°, and the residue
also extracted with chloroform. The two chloroform extracts were
united, and the residue, after evaporating off the solvent, incinerated
with fusion mixture. The amount of phosphoric acid in the ash was
estimated, and from the results, the lecithin-content calculated. The
amount of lecithin from several species of animals varied (as a mean
of several analyses in each case) between 0.0109 and 0.0833%.

S. B. S.

Detection of Indican in Urine. Ernst Salkowski (Zeitsch.,
physiol. Chem., 1908, 57, 519–521).—The urine is mixed with
copper sulphate solution and hydrochloric acid, and then chloroform
added; the chloroform is coloured blue if indican is present. This
method is described with full details, as to procedure and the pre-
cautions to be observed.

Gautier’s statement that the urine of rabbits fed on cabbage does
not contain indican is incorrect. W. D. H.

The Guaiacum Reaction. Carl L. Alsberg (Arch. exp. Path.
Pharm., Suppl., 1908, 39–53).—Various points in relation to this
test for blood are discussed, and its unsatisfactory nature pointed out.
The blood of many invertebrates gives the reaction, and particular
attention has been paid to blood which contains hemocyanin. This
blood gives the test even after it is boiled. Haemocyanin itself,
other copper compounds, certain manganese compounds, and other
salts give the test.

W. D. H.

Estimation of Catalases and Oxydases in Blood. I. Walther
Löhr (Biochem. Zeitsch., 1908, 13, 339–347).—A preliminary account
is given of the apparatus employed for the estimation of the amount
of oxygen evolved when a hydrogen peroxide solution is treated with
blood. The gas evolved was measured both by a “volume method”
and a "pressure method." In the former case, the vessel containing the peroxide was connected with a Hempel burette, and in the latter, with a manometer. The blood in both cases was contained in a small capsule resting on a plate which was fixed on to a ground stopper inserted into the side of the peroxide containing vessel above the level of the liquid. By turning the stopper through 180°, the capsule could be dropped into the peroxide solution. This was only done when the apparatus was in connexion with the burette or manometer, and had reached the constant temperature at which the experiment was carried out.

S. B. S.

Diazo-reaction of Atoxyl. Ercole Covelli (Chem. Zeit., 1908, 32, 1006).—Solutions of atoxyl give the following reactions: (1) with a hypochlorite, a yellow precipitate or coloration; (2) with a hypochlorite, phenol, and ammonia, a blue coloration, which can be observed even in a dilution of 1:100,000; (3) with reducing agents, such as zinc and sulphuric acid in the cold, or stannous chloride or hypophosphorous acid in hot hydrochloric acid, a yellow precipitate; and (4) with a fatty aldehyde and a hot mineral acid, a yellow coloration.

More delicate and characteristic reactions are given by arsenodiazobenzene, which is formed when atoxyl is treated with a few drops of a 1/2% solution of sodium nitrite and a few drops of sulphuric acid. The resulting solution gives: (a) with α-naphthylamine hydrochloride, a purplish-red coloration. This extremely delicate reaction is recommended for the detection of unchanged atoxyl, for example, in urine. Carbamide and the amino-acids, which react with nitrous acid, do not interfere with the test. The reaction may be employed also for the colorimetric estimation of atoxyl; (b) with a few drops of acetaldehyde and potassium hydroxide, added drop by drop, a carmine-red coloration, changing to yellow, and finally becoming colourless. The carmine-red is stable in presence of an excess of alkali; and (3) with phenols, such as β-naphthol, abrastol, resorcinol, morphine, or dionine, a purplish-red coloration. Towards biliverdin and pathological urines, which give Ehrlich's diazo-reaction, arsenodiazobenzene behaves in the same manner as sulphodiazobenzene.

G. Y.
General and Physical Chemistry.

Refractive Indices of Solutions. Frederick H. Getman and F. B. Wilson (Amer. Chem. J., 1908, 40, 468—484).—The specific refraction of various salts, acids, and non-electrolytes in water, calculated on the assumption that the refractive powers of solvent and solute are uninfluenced by the act of solution, have been compared with their specific refractions calculated from atomic refractions.

The lack of agreement in most of the cases studied is supposed to indicate the presence of hydrates in solution, but it has not been found possible to calculate the degree of hydration from the results.

R. J. C.

Refractometric Studies of some Methane Derivatives in which Two or Three Atoms of Hydrogen are Replaced by Negative Radicles. II. Sodium Salts. Albin Haller and Paul Th. Muller (Ann. Chim. Phys., 1908, [viii], 15, 289—296).—Mainly a résumé of work already published (Abstr., 1905, i, 112); the difference between the values of M_p for free acid and sodium salt in the case of ethyl cyanoacetoacetate is 3.74; the acid therefore is a pseudo-acid. The possible constitutional formulæ of the sodium salts of the pseudo-acids are discussed.

M. A. W.

Atomic Decomposition and Spectral Series. August L. Bernoulli (Physikal. Zeitsch., 1908, 9, 745—749; Ber. deut. physikal. Ges., 1908, 6, 636—642).—The author supposes that the molecules of a gas are not alike, but that the molecular and atomic weights represent average values. On the assumption that every chemical element in the gaseous condition represents a conglomeration of polymerised forms of a primordial matter in equilibrium, and that the gas mixtures obey Rayleigh’s radiation law, a formula is deduced from which the atomic weights of the elements can be calculated. The formula is written

\[ A = 1.0104 \left( \frac{-1 - \sqrt{3}}{2} \right)^p \left( \frac{-1 + \sqrt{3}}{2} \right)^q, \]

\( p \) and \( q \) being integral numbers. Using different values of \( p \) and \( q \), atomic weight numbers in very good agreement with the experimental values are obtained.

Similar assumptions to the above have led the author to a formula which gives the lines and bands in the spectra of the elements with considerable accuracy.

H. M. D.

Flame Spectrum of Cupric Chloride. Peter Kien (Zeitsch. wiss. Photograph. Photophysik. Photochem., 1908, 6, 337—358).—The first part of the paper contains an historical review of previous investigations on the spectrum of cupric chloride; in the second, new experiments are described, the object of which was to determine the intensity and the structure of the bands.

The cupric chloride was introduced into the flame of a blow-pipe.
fed with coal-gas and air, or oxygen, by means of a roll of filter paper moistened with a solution of the salt. By means of a spring and clockwork mechanism, the filter paper roll was moved up into the flame at a definite rate, and a steady supply of cupric chloride thereby obtained.

The intensity of the spectrum is not greatly influenced by the temperature, but depends very much on the amount of cupric chloride in the flame. As already pointed out by Lecoq de Boisbaudran, four stages of the spectrum, depending on the amount of salt in the flame, can be distinguished. The author’s observations agree very well with those of Boisbaudran, except in the fourth stage, when an extremely small amount of salt is present; in these circumstances the only remaining band of any considerable strength reaches from \( \lambda = 5100 \) to \( \lambda = 5800 \), and has a maximum at \( \lambda = 5400 \) — 5600.

The four characteristic double bands which are seen in the second stage: \( \alpha (\lambda = 4259 - 4279) \), \( \beta (\lambda = 4333 - 4353) \), \( \lambda (4412 - 4433) \), and \( \delta (4493 - 4515) \), are found with great dispersion to consist of groups of bands in which series of lines can be recognised.

Attention is called to the sensitiveness of the cupric chloride spectrum. Photographic registration of the “sodium chloride” spectrum in coal or coke fires has confirmed Salet’s conclusion that this is due to traces of cupric chloride.

**Spectrum of Neo-erbium Oxide and Kirchhoff’s Law.** Karl A. Hofmann and Günther Bugge (Ber., 1908, 41, 3783—3789. Compare Hofmann and Burger, this vol., ii, 189).—The reflection spectrum of neo-erbium oxide illuminated by an electric arc light is far more characteristic than the absorption spectrum of a 10% solution of the nitrate, and, in agreement with Kirchhoff’s law, it is found that the lines of maximum absorption in the former spectrum correspond with the bright lines in the emission spectrum of the oxide heated with a hydrogen flame. The bands of maximum absorption of the nitrate solution do not exactly correspond with the lines of the oxide spectrum, but are somewhat displaced; thus, the maxima of emission of the oxide are: \( \lambda = 661 \cdot 3, 653 \cdot 0, 563 \cdot 4, 540 \cdot 2, 522 \cdot 6, 493 \cdot 0, 489 \cdot 1, 463 \cdot 0, \) and \( 447 \cdot 0 \); the maxima of absorption of the oxide are: \( \lambda = 661 \cdot 7, 652 \cdot 4, 563 \cdot 8, 540 \cdot 4, 522 \cdot 4, 491 \cdot 5, 489 \cdot 5, 462 \cdot 5, \) and \( 446 \cdot 5 \); and of the nitrate solution, \( \lambda = 667, 654, 541, 523, 519, 492, 487, 450, \) and 442. Both the oxalate and fluoride in a solid state give absorption spectra very similar in character to the absorption spectra of solutions of the nitrate and sulphate, although the intensities and positions of the bands vary slightly in each case. Sharp lines as well as bands appear in the absorption spectrum of the solid sulphate, so that a transition of the band spectrum of a salt to the line spectrum of the oxide appears probable.

W. H. G.

**Spectroscopic Behaviour of Hydrocarbons with Conjugate Ethylene Linkings.** Julius W. Brühl (Ber., 1908, 41, 3712—3720. Compare Trans., 1907, 91, 115).—Reif’s results (this vol., i, 847) confirm the author’s previous conclusions. The values for the refractive dispersions \( \Delta \beta^A \)-hexenol and \( \Delta \beta^A \)-hexadiene have been re-determined and Reif’s results confirmed.
In the latter compound, the values indicate exaltations of $+1.49$, $+1.71$, and $+0.52$ units in the values for $(n_a^2 - 1)/(n_a^2 + 2) \times P/d$, $(n_b^2 - 1)/(n_b^2 + 2) \times P/d$, and $M_\gamma - Ma$ respectively.

Using the formula $(n^2 - 1)/n^2 + 2 \times P/d$, the following values have been calculated for $\Delta^{2\gamma c}$-hexatriene from W. H. Perkin's numbers:

$$
\begin{align*}
H_a & : 30.59 \\
D & : 31.03 \\
M_\gamma - Ma & : 2.22
\end{align*}
$$

which indicate exaltations of 2.07, 2.49, and 1.01 units respectively. These results are striking when compared with the normal optical behaviour of benzene, $\Delta^{1,3,5}$-cyclohexatriene, which shows practically no exaltation. Harries and Majima’s $\Delta^{1,3}$-dihydrocyrime (this vol., i, 733) also exhibits characteristic exaltations, due to conjugated ethylene linkings.

It is pointed out that the intermediate product described by Auwers and Hessenland (this vol., i, 551) in the preparation of $\Delta^{1,3}$-dihydro-p-xylene, and stated to be the corresponding acid, cannot have this constitution, as its methyl ester exhibits no exaltation, but is optically normal. It is suggested that the ethylene linkings in the acid are not in conjugate positions.

Zelinsky and Gorsky (this vol., i, 619) claim to have prepared dihydrobenzenes which give normal molecular refractions and dispersions, although they contain conjugated ethyl linkings. It is pointed out that these authors have not conclusively proved the constitution of their compounds by the examination of decomposition products. J. J. S.

—Aniline-p-sulphonic acid has been found to lose its water of crystallisation more readily when exposed to light than when kept under exactly similar conditions in the dark. Careful observations showed that, although the temperature of the specimens exposed to direct sunlight was 2.86° lower than those screened from such light by black paper, yet the former lost more than 98% of their water of crystallisation during ten winter days’ exposure, whilst the latter only lost 35% during the same period. From determinations of the solubility of the product, no evidence was obtained of any transformation having taken place into the ortho- or meta-compound. When hydrated sulphanilic acid or the product obtained after exposure to sunlight was crystallised from water above 80°, it was found to be in an anhydrous state, whilst from water at 40° the crystals obtained had again 2H2O.

J. V. É.

Violet Coloration Produced in Glass by the Influence of Light. J. G. Maschhaupt (Chem. Weekblad, 1908, 5, 807–808).—The author attributes the violet colour sometimes developed in the glass of old mirrors to the action of sunlight, and describes experiments in support of his contention.

A. J. W.

Some Reflections on Radiology. Albert Reygher (Bull. Soc. chim., 1908, [iv], 3, 1009–1012).—Rutherford and Soddy’s theory that radioactive substances consist of unstable, large accumulations of particles of a primordial matter, which are liable to internal
changes and decompositions, tending towards closer and more stable
arrangements of the particles, does not in the author's view account
for all the facts observed, and particularly for (a) the large amounts
of energy disengaged and (b) the conversion of an atom of uranium
into several atoms of helium (?) and one atom of radium, which is more
voluminous and more active than that of the parent substance.

These difficulties disappear if the ether is taken as the primordial
matter, and is regarded as existing in elementary atoms in two forms,
namely, condensed, as nodules, an accumulation of which forms the
atom, and also in the free state. If the intra-atomic transpositions
may then be regarded as involving also the condensation of the free
ether, the changes which occur can be represented thus: radium +
ether = α-particles + β-particles + emanation. This view would
explain the discrepancy between Ramsay and Rutherford's estimates
of the length of "life" of a radium atom, that of the former being
too short. It implies, however, that radioactive matter enclosed in
a glass tube should gain in weight, since the ether would have free
access and only β-rays could escape. The β-rays it is suggested,
however, may be in part an inflow of electropositive ether.

T. A. H.

Extraordinary Radioactivity of Water from a Spring at
Valdemorillo. José Muñoz del Castillo (Anal. Fis. Quim., 1908,
6, 398—400).—Samples of water from a spring at Valdemorillo were
found to have radioactivities varying from 27,000 to 51,687 volts per
hour-litre. The latter value is remarkably high, and much exceeds
that found with the waters from Lerez (10,000—12,000 volts per
hour-litre: compare Abstr., 1907, ii, 218; this vol., ii, 750).

W. A. D.

Radioactivity of Three Springs at Oña (Burgos). José
Muñoz del Castillo (Anal. Fis. Quim., 1908, 6, 400—402).—The
following table shows the character of the rock through which the
springs percolate, and the radioactivity of the water and mud therefrom
in volts per hour-litre:

<table>
<thead>
<tr>
<th>Rock</th>
<th>Activity of water</th>
<th>Activity of mud</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spring A</td>
<td>Argillaceous limestone</td>
<td>34·8</td>
</tr>
<tr>
<td>&quot; B</td>
<td>Cretaceous</td>
<td>30·0</td>
</tr>
<tr>
<td>&quot; C</td>
<td>Argillaceous</td>
<td>12·8</td>
</tr>
</tbody>
</table>

Spring B is one of considerable volume feeding the river Oca.
All three springs come to the surface within a radius of 200 metres
from one another. It is probable that all three springs arise from
a common source; the difference between the values for the mud of
B and that from A and C is probably due merely to the muds being
of different consistency.

W. A. D.

Radioactivity of the Gases of the Thermal Spring of
Uriage (Isère). Gustave Massol (Compt. rend., 1908, 147,
844—846).—During the passage of the water through a siphon to
the reservoir, very variable quantities of gas are evolved; determina-
tions in two successive half-hours (when a considerable volume of water was flowing) gave 538 litres and 724 litres respectively. Of this gas, 7% is soluble in potassium hydroxide solution (carbon dioxide and hydrogen sulphide), whilst the remainder consists of nitrogen and allied gases. The radioactivity of the gas, as measured by a Curie electroscope (as modified by Chéneveau and Laborde), was 0.150 and 0.144 per 10 litres of gas (at 20° and 745 mm.), the radioactivity of the emanation per minute from 1 mg. of radium being taken as the unit. These results are not strictly comparable with Besson’s (following abstract), since the latter refer to the gas dissolved in the water, of which 64.6% is insoluble in potassium hydroxide solution (Lefort found that 1 litre of the water of Uriage contains 3.2 c.c. CO₂, 7.44 c.c. H₂S, and 19.5 c.c. N₂). For the radioactivity of the gas remaining dissolved in the water, the author obtains the value 0.500 per 10 litres. The saline residue left on evaporating the water, the deposit formed in the reservoir, and the rock from which the water flows are all quite inactive.

Radioactivity of the Waters of Uriage-les-Bains (Isère).

Paul Besson (Compt. rend., 1908, 147, 848—850. Compare preceding abstract).—Three litres of the water were boiled for one hour, the gases evolved being collected over mercury and dried by means of potassium hydroxide and phosphoric acid. After keeping for three hours, the radioactivity of the gas was measured by means of the Chéneveau and Laborde modification of the Curie electroscope. For the gas from 10 litres of water, the values 0.012, 0.015, and 0.018 in mg.-minute units were obtained at pressures of 745 mm., 740 mm., and 735 mm. respectively. Thus the value seems to increase as the atmospheric pressure decreases. This observation of radioactivity in a mineral water containing 6.0567 grams of sodium chloride and 3.311 grams of calcium, magnesium, and sodium sulphates is in accordance with Kosler’s work on the solubility of the emanation in saline solutions. The period of half-decay according to Curie’s law is four days. The residue left on evaporation is inactive.

The ferruginous water has the very low radioactivity 0.003 mg.-minutes.

Absorption of the Radioactive Emanations by Charcoal.

R. W. Boyle (J. Physical Chem., 1908, 12, 484—506).—Experiments have been made to determine how the absorbing power of charcoal for the emanations of radium and thorium depends on the conditions.

The absorbing power of charcoal for radium emanation at the ordinary temperature is considerable, but the rate of absorption soon falls off, owing to saturation of the upper layer and the comparatively slow rate of diffusion to the lower layers.

The majority of the experiments were made with thorium emanation. As the rate of decay of the emanation is so great, the observations were made by leading the latter, mixed with air, through tubes containing various absorbing or non-absorbing materials, and estimating its activity by measuring the ionisation of air produced. The results are given in the form of tables and curves, the latter being
obtained by plotting the ionisation current against the speed of the air current.

The degree of absorption of the emanation depends: (1) on the speed of the air current, being diminished by increasing the speed; (2) on the nature of the charcoal, being greatest for cocoanut, intermediate for animal, and least for wood, charcoal; (3) on the extent of absorbing surface exposed, being greatest for the most finely-divided charcoal, and (4) is greater the lower the temperature.

G. S.

Action of the Radium Emanation on Water. Ernest Rutherford and T. Royds (Phil. Mag., 1908, [vi], 16, 812—818. Compare Cameron and Ramsay, Trans., 1908, 93, 992).—Preliminary experiments are described, the object of which was to ascertain the minimum amount of neon which can be detected spectroscopically. Small quantities of air were subjected to the action of cocoanut charcoal, cooled by liquid air, and the residual gas introduced into a small spectrum tube, 7 cm. long and 1 mm. in diameter, and examined for neon. Operating on 1/15 c.c. of air, the yellow line of neon is readily observed; with 2/15 c.c. of air, the red lines of neon are clearly visible, and with 1/5 c.c. of air, a brilliant neon spectrum showing most of the lines is obtained. Since, according to Ramsay, one volume of neon is contained in about 100,000 volumes of air, these experiments show that less than one-millionth of a c.c. of neon can be detected spectroscopically.

The gases formed by the action on water of a quantity of emanation, corresponding with the equilibrium amount from 150 mg. of radium, were then examined in a similar manner, after the hydrogen and oxygen had been removed by explosion. A complete and brilliant spectrum of helium was found, but there was no trace of a neon spectrum. In all, five experiments were made; neon was only observed in one case, and was found to be due to a small air leak. The gases obtained from the aqueous solution of the radium salt, from which the emanation had been pumped off, also showed no trace of neon when examined in the same way.

The positive results obtained by Cameron and Ramsay in similar experiments are attributed to the leakage of air into the apparatus used.

H. M. D.

Nature of the Positive Rays. Wilhelm Wien (Sitzungsber. K. Akad. wiss., München, 1908, 55—65).—Experiments are described the object of which was to find an explanation for the well-known fact that the canal rays are unequally deviated under the influence of a magnetic field. The results indicate that this lack of uniformity cannot be due to the ions having different masses, but is a consequence of differences in the lengths of the paths which they traverse in the charged condition. The nature of the canal rays is determined by a condition of equilibrium, in which the ratio of the charged to the uncharged particles has a constant value. Under the influence of a magnetic field, some of the charged particles are removed, but the condition corresponding with the equilibrium ratio is immediately restored by dissociation of the atoms.

H. M. D.
β-Rays of Actinium. Otto Hahn and Lise Meitner (Physikal. Zeitsch., 1908, 9, 697—702).—The β-rays emitted by actinium are not absorbed by aluminium according to an exponential formula. With gradually increasing thicknesses of aluminium, the absorption is at first more rapid than that required by such a formula; in the second stage, the absorption is exponential, whilst in the third, a more rapid rate of absorption is again found. It is found that the increase in the absorption in the third stage is dependent on the experimental arrangements.

The large value of the absorption coefficient for small thicknesses of the absorbing layer is found to be due to the emission of easily absorbed β-rays by radio-actinium. This was separated from the other products of disintegration, and its β-ray activity examined. In addition to β-rays, which are absorbed to the extent of 50% by 0·04 mm. of aluminium, it emits a much more penetrating type of radiation, which consists either of hard β-rays or soft γ-rays.

β-Rays are also emitted by actinium A and actinium C. The former are absorbed even more readily than the soft β-rays of radio-actinium; the latter are absorbed to the extent of 50% by 0·24 mm. of aluminium.

The view that homogeneous products emit homogeneous β-radiation is confirmed by the results of this investigation. H. M. D.

Influence of Pressure on Ionisation Produced in Gases by the X-Rays. The Saturation Current. E. Rothené (Compt. rend., 1908, 147, 785—788).—A method is described for studying the influence of pressure on ionisation phenomena in general, and details are given of the precautions necessary to secure regular working of the Crookes' tube. The author shows that the intensity of the saturation current is proportional to pressure from 0·1 to 5 atmospheres.

Volatilisation Produced by Canal Rays. Johannes Stark (Zeitsch. Elektrochem., 1908, 14, 752—756).—The canal rays consist of charged or uncharged atoms or molecules projected with great velocity. When such particles strike a metal, they impart their velocity to one or more atoms of the metal, which may rebound with sufficient violence to pass away from the surface of the metal. The consequences of this idea are followed out, and the author thinks that the cathodic volatilisation of metals is better explained in this way than by Kohlschütter's chemical theory (this vol., ii, 457). T. E.

For aqueous solutions in which the iodine concentration is small, the observed values of the E.M.F. of the concentration cell are in good agreement with those calculated from Nernst's equation when
the free iodine concentrations are determined from the equilibrium constant corresponding with the dissociation equation: \( \text{KI}_3 \rightarrow \text{KI} + \text{I}_2 \). For more concentrated solutions, the observed values differ sensibly from those obtained by calculation.

Similar relationships between the two series of numbers are found in the case of alcoholic solutions, and the conclusion is drawn that Nernst's equation also applies to these solutions and that they contain potassium tri-iodide like the aqueous solutions.

Measurements in aqueous alcoholic solutions show that the \( E.M.F. \) of a given concentration cell increases as the proportion of alcohol in the mixture increases.

When solutions containing equal quantities of iodine and potassium iodide in water and alcohol respectively are opposed to one another, a considerable \( E.M.F. \) is obtained. The action of the cell involves the transfer of iodine from the aqueous to the alcoholic solution, and the transfer of potassium iodide in the reverse direction. In both cases the transference is towards the solvent in which the substances dissolve more readily.

H. M. D.

**Explanation of Supertension. III and IV.** Felix Kaufler (Zeitsch. Elektrochem., 1908, 14, 737—741, 749—752).—In consequence of Müller's criticism (this vol., ii, 802), the author has made measurements of the difference of potential between lead or smooth platinum cathodes and a solution of acetophenone or benzophenone in aqueous alcohol containing potassium acetate during electrolysis. These show that, under the same conditions, the fall of potential between the solution and the cathode is greater with lead than with platinum.

The resistance of a cell with a mercury cathode and an anode of platinum or of lead in which the electrolyte is sulphuric acid of maximum conductivity is measured during the passage of a current. With a low current density (under 0.05 ampere per sq. cm.) the attainment of a steady condition is extremely slow. The resistance of the cell is much larger than that observed with no current flowing; it is greatest with small current density, and is not dependent on the nature of the anode. Stirring the mercury does not change the resistance. As in the case of lead previously investigated (this vol., ii, 558), the author assumes the existence of a film of a hydride of high resistance on the surface of the mercury. The product of film resistance and current, which is the supertension due to the transition resistance at the surface of the cathode, is approximately independent of the current density and varies from 0.05 to 0.1 volt.

T. E.

**Influence of the Velocity of Ionic Reactions on the Current-Potential Curve.** Arnold Eucken (Zeitsch. physikal. Chem., 1908, 64, 562—580).—The relation of current and potential has been studied in the double cyanides of potassium with silver, gold, copper, and mercury, but only the first of these allows of the production of a limiting current independent of the potential. The velocity of dissociation, \( \text{Ag(CN)}_2^- \rightarrow \text{Ag}^+ + 2(\text{CN})^- \), is very great. The finite
velocity observed by Caspari (Abstr., 1900, ii, 7) is due to a secondary reaction. The smaller the velocity of the ionic reaction the smaller is the limiting current.

The velocity of dissociation of acetic, lactic, and benzoic acids has been calculated from the results of previous observers. C. H. D.

Specific Charge of the Ions Emitted by Hot Substances. Owen W. Richardson (Phil. Mag., 1908, [vi], 16, 740—767).—The ratio of the electric charge to the mass of the positive ions emitted by hot substances has been determined by measurements of the deflexion of the path, due to the action of a transverse magnetic field on the ions when moving in a uniform electric field.

The experimental data indicate that the ratio of the mass to that of the hydrogen atom is the same for the ions from carbon and platinum, and this is very nearly equal to the corresponding quantity determined by J. J. Thomson for the ions from iron. The values are respectively: for platinum, 25.7; for carbon, 27.6; and for iron, about 24.

These numbers show that the positive ions cannot be atoms of the metal or atoms of absorbed hydrogen; neither can they be regarded as identical with the positive electrons found by Thomson in the canal rays.

The emitted ions appear to be quite homogeneous, and experiments carried out between 750° and 1200° indicate that the ratio of charge to mass does not depend on the temperature of the hot substance in any simple way.

The mass ratios in terms of hydrogen are not very different from the molecular weights of nitrogen, carbon monoxide, and oxygen, but there is no evidence that the different substances evolve one or other of these gases when heated. The author, on the other hand, thinks it possible that the positive ionisation is due to a real constituent which is common to the different elements examined. In this case it is necessary to assume that the ions carry a charge which is smaller than the generally recognised fundamental electronic charge. H. M. D.

Determination of the Hydration of Ions by Transference. Experiments in the Presence of a Non-electrolyte. Edward W. Washburn (Tech. Quart., 1908, 21, 288—320).—Experiments have been made to determine the transference of water which accompanies the migration of ions in aqueous solution by the measurement of transport numbers in presence of a third constituent, or reference substance, which remains stationary during the passage of the current. By referring the changes in concentration of the water and of the electrolyte to this third substance, the amounts of each transferred are calculated, and from these "true" transference numbers have been obtained.
Sucrose, raffinose, and arsenious acid were used as reference substances, the first two substances being estimated polarimetrically, the third by means of an iodine solution. The behaviour of arsenious acid is uncertain, on account of its ready oxidisability. A description of the transport apparatus has been previously given (this vol., ii, 805).

The experimental data show that the electrolysis of solutions of potassium, sodium, or lithium chloride containing one of the above reference substances is attended by an increase in the ratio of the quantity of non-electrolyte to that of water at the anode, and by a corresponding decrease at the cathode. It is shown that this is due chiefly, if not wholly, to a transfer of water from the anode to the cathode. From the measured changes, the relative degrees of hydration of the chlorine, lithium, sodium, and potassium ions have been calculated. On the assumption that the chlorine ion is not hydrated, the minimum hydration values of the cations have been calculated; these correspond with the formulae: $K(H_2O)_{13}$, $Na(H_2O)_{20}$, and $Li(H_2O)_{17}$. From Buchbóck's data for hydrochloric acid solutions, the minimum hydration value for the hydrogen ion corresponds with $H(H_2O)_{03}$. Absolute values for the hydration cannot be obtained until the hydration value of some one ion has been determined by some other method.

On account of this transference of water during electrolysis, the transport numbers hitherto obtained for more concentrated solutions of the alkali metal chlorides are erroneous. The true transference numbers are found to vary with the concentration much less than the apparent values obtained by the ordinary Hittorf method.

The true values are also given by the method of moving boundaries, and the author's data are found to agree very well with the results of Denison and Steele obtained by this method.

H. M. D.

**Variation of the Degree of Dissociation of Certain Electrolytes with Temperature.** Adolfo Campetti (Atti R. Accad. Sci. Torino, 1908, 43, 1071—1094).—The author has determined the conductivities, the temperature-coefficients of conductivity, and the degrees of dissociation of solutions of zinc and magnesium sulphates and of sulphuric acid for temperatures varying from $10^\circ$ to $90^\circ$ and for concentrations $3\cdot0—0\cdot001N$.

The variation of the dissociation with the temperature is, as far as its sign is concerned, in agreement with van't Hoff's law. For an interval of concentration which is not too great, the degree of dissociation is best expressed as a function of the concentration by van't Hoff's formula: $K = a^{2/3}c^{1/2}/(1 - a)$, the expression given by Rudolphi, $K = a^{2/3}c^{1/2}/(1 - a)$, yielding somewhat less concordant results.

Integration of van't Hoff's formula, $q = -RT^2/K.dK/dT$, assuming that the heat of dissociation, $q$, per gram-molecule is constant for the temperature interval, $T_2 - T_1$, leads to the expression $q(T_1 - T_2)/T_1T_2 = 4\cdot58[\log\{a_2^3/(1 - a_2)\} - \log\{a_1^3/(1 - a_1)\}]$, which is found
to be approximately true with magnesium sulphate and with sulphuric acid.

In solutions of magnesium sulphate or zinc sulphate, the undissociated molecules give rise to complex molecules.

T. H. P.

Conductivity and Ionisation of Electrolytes in Aqueous Solutions as Conditioned by Temperature, Dilution, and Hydrolysis. Harry C. Jones and C. A. Jacobson (Amer. Chem. J., 1908, 40, 355—410. Compare Abstr., 1905, ii, 794).—So many conflicting results have been published on the question of the influence of temperature on dissociation that the authors were induced to re-investigate the subject. The method employed was that previously described by Jones and West (Abstr., 1905, ii, 794), the temperature at which observations were made also being the same. Twenty-eight inorganic salts and six organic acids have been investigated; the molecular conductivity and percentage of dissociation at 0°, 10°, 25°, and 35° at eight dilutions are tabulated, also the temperature-coefficients in each case. The results are in agreement with the well established facts that (1) the molecular conductivity of electrolytes increases with rise of temperature; (2) the conductivity increases with increase in dilution up to a certain maximum value; (3) dissociation increases with increase in dilution up to the point of complete dissociation. At the somewhat low temperatures of these observations, no maximum in the conductivity curve, as described by Sack, Kohlrausch, and Noyes, was observed. Further, it was found that the conductivity of water increases as a linear function of the temperature, but the molecular conductivity of electrolytes in aqueous solution increases as a parabolic function of the temperature from 0° to 35°. The increase in conductivity of electrolytes causing the departure from a straight line is largely due to their being more or less hydrated; the rise in temperature diminishes the extent of this hydration, allowing the ions to move with less friction, and thus show an increase of conductivity. In support of this view, those salts which are strongly hydrated in solution are found to exhibit a greater increase in conductivity with rise of temperature than the salts that are slightly hydrated. The conclusion is also drawn from the results given that nearly all, if not all, electrolytes are hydrolysed in dilute solutions, and this greatly influences the true dissociation value. When the temperature-coefficients expressed as conductivity units are examined, they are all found to increase as the dilution increases, and for every salt they increase with rise of temperature; but the organic acids, on the other hand, have decreasing temperature-coefficients with increase of temperature.

J. V. E.

Basicity of Acids as Determined by their Conductivities. M. R. Schmidt (Amer. Chem. J., 1908, 40, 305—313).—After considering the work of Miolati and Mascetti (Abstr., 1901, ii, 381) on the effect of alkalis on the conductivity of solutions of various acids, and the anomalous behaviour of hydrogen fluoride solutions in this connexion (Pellini and Pegoraro, Abstr., 1907, ii, 860), the author gives his results of a study of the conductivity change when potassium...
hydroxide is added to moderately strong solutions of phosphoric acid. Working with 0.2 N, 0.1 N, 0.04 N, and 0.02 N solutions of phosphoric acid, it was found that in the case of 0.2 N solutions, the minimum occurs when only about 40% of the amount of potassium hydroxide required for one-third neutralisation had been added. In the more dilute solutions, the minimum shifts continually towards the point corresponding with the salt KH₃PO₄, reaching it with 0.02 N solutions. As a possible explanation of this, it is suggested that, as more and more potassium hydroxide is added, the H ions of the phosphoric acid are replaced by K ions, which move more slowly, and, as a result, the conductivity of the mixture decreases. But phosphoric acid being far from completely dissociated in strong solutions, when a small quantity of base is added, practically all the hydrogen ions present are neutralised. Immediately, however, more dissociate, and in sufficient quantity to overbalance the decrease in conductivity caused by the substitution of K ions for the H ions, thus causing the conductivity to rise again.

A minimum thus appears before enough alkali has been added to form the primary salt. Furthermore, as the dilution increases, the phosphoric acid becomes more and more completely dissociated according to the formulation H₃PO₄ ≡ H⁺(H₂PO₄), thus lessening the overbalancing effect of secondary dissociation previously mentioned.

J. V. E.

Comparative Investigations on the Formation of Salts and the Basicity of Acids. Giuseppe Bruni (Zeitsch. Elektrochem, 1908, 14, 729—734).—The molecular conductivity of an acid of which a fraction x is neutralised is Λ = x(lₓ + lₜ) + (1 − x)a(lₓ + lₜ), where lₓ, lₜ, and lₓ, are the mobilities of the metallic ion, the anion, and the hydrogen ion respectively, and a is the fraction of the acid which is dissociated. The salt is supposed to be completely dissociated. Assuming that the acid follows Ostwald’s dilution law, a can be expressed in terms of known quantities. This gives an expression for the conductivity which reproduces all the peculiarities of the curves obtained by the author (this vol., ii, 935).

T. E.

Certain Phenomena in Gases Subjected to the Action of Spark Discharge or Arc Light. Heinrich Rausch von Traubenberg (Physikal. Zeitsch., 1908, 9, 713—726).—Measurements have been made of the electrical conductivity of certain gases during, and after, the passage of electricity through them in the form of a spark discharge and of direct and alternating current arcs. The gases examined were hydrogen, oxygen, acetylene, carbon dioxide, air, coal gas, and carburetted hydrogen. The high conductivity, which is observed during the period of the spark or arc discharge in all cases, persists for several hours after the discharge is stopped in the case of acetylene and coal gas. The phenomenon was investigated more closely in the case of coal gas, and found to depend on the material of the electrodes, and on the nature of the discharge. In
some cases the conductivity, which is unipolar in nature, was found to decrease slowly, whilst in others it increased. No evidence of a saturation current could be obtained. The last part of the paper is devoted to a theoretical discussion of the possible modes of electrical transport through the conducting gases.

H. M. D.

Hysteresis of Certain Iron Compounds. G. Berndt (Physikal. Zeitsch., 1908, 9, 750—752; Ber. deut. physikal. Ges., 1908, 6, 662—666*).—The magnetic properties of ferric oxide, ferric hydroxide (impure), ferric chloride, and ferrous and ferric sulphates have been examined. The oxide and hydroxide exhibit well-developed hysteresis; in the case of the salts, no such effect could be detected. As the strength of the field increases, the magnetic susceptibility of the oxide diminishes considerably, and that of the hydroxide slightly.

H. M. D.

Magnetic Properties of the Oxygenated Metallic Radicles. P. Pascal (Compt. rend., 1908, 147, 742—744. Compare this vol., ii, 756, 927).—By measuring the magnetic susceptibilities of their solutions, the author has obtained the following values for the molecular magnetic susceptibilities at 23°: of manganese sulphate, +1500 x 10^{-5}; potassium permanganate, +25.5 x 10^{-5}; chrome alum, +2 x 629 x 10^{-5}; chronic acid, -0.5 x 10^{-5}; vanadium chloride, +139 x 10^{-5}; sodium metavanadate, -30.2 x 10^{-5}. Comparison of each pair of salts shows that oxidation of the metal results in a diminution in the magnetic susceptibility; the molybdates and ferrates also, unlike the salts of molybdenum and iron, are diamagnetic.

The values for vanadium compounds: VCl₂, +139 x 10^{-5}; (V₂O₅)SO₄, 2 x 115 x 10^{-5}; vanadium tetrachloride (hydrolysed) (=V₂O₄), +66.2 x 10^{-5}, and NaVO₃, -30.2 x 10^{-5}, indicate that the magnetic properties of the vanadium ion diminish in proportion to the increase in the degree of oxidation; similarly, U(SO₄)₂ has +320 x 10^{-5}, and UO₃(SO₄), -5.57 x 10^{-5}.

These examples indicate the increasing generality of the law previously enunciated, that when the chemical properties of a metal become masked by its entry into a complex ion or colloid, the magnetic properties are similarly affected and to the same degree. An interesting example of this is afforded by vanadic anhydride, which dissolves in concentrated sulphuric acid to a red solution. The latter on dilution becomes first yellow and then colourless. The anhydride in the red solution has the molecular magnetic susceptibility -2 x 85.7 x 10^{-5}; in the yellow solution, -2 x 31.5 x 10^{-5}, and in the colourless solution, -2 x 30.2 x 10^{-5}. From these values, it is permissible to conclude that the strongly acid solutions contain red sulphovanadic compounds which dissociate on dilution. These complexes doubtless include Berzelius' vanadyl sulphate, VO₃(SO₄)₂, Ditte's compound, V₂O₅.3H₂SO₄, and Gerland's salt, 4SO₃.V₂O₅.K₂O.

E. H.

Measurements with Gas Thermometer. Arthur L. Day and J. K. Clement (Amer. J. Sci., 1908, 26, 405—463).—The
authors have endeavoured to improve the accuracy of the nitrogen in platinum standard gas thermometer between 0° and 1200°.

Particular attention was paid to uniformly heating the bulb by a series of independently regulated platinum coils whilst the unheated space between bulb and manometer was reduced to a minimum.

The whole furnace being contained in a bomb in which nitrogen was maintained at the same pressure as the thermometer, diffusion and strain on the bulb were obviated, so that much higher gas pressures could be employed than hitherto. The coefficient of expansion of the metal of the bulb was determined with great care.

The melting points of the purest commercially obtainable metals are given as follows: zinc, 418·5° ± 0·1; silver, 958·3° ± 0·5; gold, 1059·3° ± 1·0; copper, 1081·0° ± 0·5. Exact analyses of the metals are given, but different samples of ostensibly the same metal sometimes differed by 1° in melting point. It is claimed that the determinations of temperature are accurate to within half a degree. R. J. C.

Heat of Fusion, Specific Cohesion, and Molecular Weight at the Melting Point. Paul Walden (Zeitsch. Elektrochem., 1908, 14, 713—724).—For non-associated substances, the ratio \( L/a^2 \) is roughly a constant and equal to 3·6 \( (L = \text{heat of fusion}, \text{and} \ a^2 \text{the height to which the liquid rises in a capillary of 1 mm. radius at the melting temperature}) \). The expressions \( ML/T \) and \( Ma^2/T \) \( (M = \text{molecular weight}, \text{and} \ T \text{absolute melting point}) \) are also roughly constant for non-associated substances. The value of the former is 13·5, and that of the latter, 3·65. For associated substances, the degree of association may be obtained by dividing the value of the expression for any substance into the above constants. The results are in harmony with values obtained by other methods. By combining these results with Trouton's rule and van't Hoff's equations for the depression of freezing point and elevation of boiling point of solutions, it is shown that \( E_1/E = 0·64T_1/T \) and \( L/L_1 = 0·64T/T_1 \), where \( E_1, T_1, \text{and} \ L_1 \) are the molecular elevation of boiling point, the absolute boiling point, and the heat of evaporation of a liquid, \( E, T, \text{and} \ L \) being the corresponding quantities at the freezing point. The application of the equations to some metallic and non-metallic elements and fused salts gives values for the degree of association which agree with what is known on other grounds about the size of their molecules.

T. E.

Electrical Heating in Ebulloscopic Determinations and in Fractional Distillation. Ernst Beckmann (Zeitsch. physikal. Chem., 1908, 64, 506—507. Compare this vol., ii, 663; also Richards and Mathews, this vol., ii, 828).—When, in spite of electrical heating, superheating and bumping occur in ebulloscopic determinations, the difficulty can be got over by passing a current of an indifferent gas through the liquid.

An apparatus is sketched in which electrical heating has been successfully employed for the fractional separation of the chlorides of sulphur. In this way the chloride \( \text{SCl}_4 \) has been distilled off almost pure at \(-24^\circ\) under a pressure of 4 mm. J. C. P.
Quartz Protecting Tubes in Thermal Analysis. P. Schoen (Metallurgie, 1908, 5, 635—637).—Quartz tubes are to be preferred to porcelain for the protection of thermo-couples in the determination of freezing points of alloys, on account of their greater cheapness, and of the less resistance to the passage of heat. They are also less permeable than porcelain to metallic vapours. They are, however, more readily attacked by oxides. They can be used up to nearly 1500°, at which temperature they soften.

C. H. D.

Cryoscopic Investigations on Solutions of Gases in Liquids. Pietro Falciola (Atti R. Accad. Lincei, 1908, [v], 17, ii, 324—330).—The author has extended the investigations of Garelli and Falciola (Abstr., 1904, ii, 312) to the gases, carbon monoxide, nitrogen, hydrogen, oxygen, methane, and nitrous oxide, and to other solvents than those previously employed.

With water or formic acid, carbon monoxide produces a depression of the freezing point, whilst with acetic acid, benzene, and a number of other organic solvents, the freezing point is raised. Similar elevation of the freezing point of certain solvents is also produced by nitrogen, hydrogen, oxygen, and methane, but is not observed with carbon dioxide, hydrogen sulphide, acetylene, or nitrous oxide.

Benzene, the freezing point of which has been raised by means of carbon monoxide, assumes its normal freezing point gradually in the cold, but rapidly on heating. Bromoform, however, through which carbon monoxide or nitrogen has been passed, maintains its elevated freezing point for some days if kept in the dark and out of contact of the air. The phenomenon does not appear to be due to chemical action, but is probably caused by part of the gas adhering to the solvent and separating with the latter in the solid state.

The following table gives the coefficients of absorption of the various gases, calculated from the equation \( c = m\Delta/k \).

T. H. P.

An Electrically Heated Oven, with a Liquid Regulator. L. Ehrmann (Bull. Assoc. chim. Swen. Dist., 1908, 26, 272—274).—The apparatus described was constructed for the purpose of maintaining a moderately low temperature in an oven. An ordinary electric lamp is used as the source of heat, and the temperature is regulated by means of a tall cylindrical vessel containing very dilute sulphuric acid. A glass tube carrying a platinum wire is inserted through a cork in a tubulure at the bottom of the cylinder, and a long glass tube carrying a second platinum wire is passed through a cork at the top of the cylinder. This upper tube is made to move freely through the cork, so that the distance between the upper and lower platinum wires may be adjusted as desired. The cylinder is inserted in the circuit feeding
the lamp, and by altering the distance between the platinum wires the degree of heat obtained from the lamp may be regulated as desired. A second form of regulator is also described. It consists of a glass vessel containing the acidified water, and in the latter are placed two copper plates, one fixed and the other movable, the method of using this regulator being similar to that mentioned above. In both cases, means are provided for changing the direction of the current from time to time in order to prevent polarisation. W. P. S.

Thermodynamics of Salts containing Water of Crystallisation. HERMANN SCHOTTKY (Zeitsch. physikal. Chem., 1908, 64, 415—448).—The author applies Nernst's theory (Abstr., 1907, ii, 153) to the case of formation of a higher hydrate from a lower one and water, and deduces from it the relationship \( Q - A = T(\frac{C}{C'} - 1) \), where \( Q \) and \( A \) are referred to the combination of 1 molecule of water, \( C \) is the molecular specific heat of ice, and \( C' \) is the heat capacity of the combined molecule of water of crystallisation. For the purpose of testing this formula, the values of \( Q \) and \( C - C' \) are obtained from thermochemical data, and \( A \) is calculated from the tension of the vapour over the hydrates.

The four cases selected for examination are: (1) \( \text{CuSO}_4 + \text{H}_2\text{O} = \text{CuSO}_4\cdot\text{H}_2\text{O} \); (2) \( \text{K}_4\text{FeCy}_6 + 3\text{H}_2\text{O} = \text{K}_4\text{FeCy}_6\cdot3\text{H}_2\text{O} \); (3) \( \text{BaCl}_2 + \text{H}_2\text{O} = \text{BaCl}_2\cdot\text{H}_2\text{O} \), and (4) \( \text{BaCl}_2\cdot\text{H}_2\text{O} + \text{H}_2\text{O} = \text{BaCl}_2\cdot2\text{H}_2\text{O} \).

In order to supplement the few data already available in these cases, the author has determined (1) the specific heats of the hydrates; (2) the heats of hydration; (3) the dissociation pressures. The values obtained differ in some cases from those recorded by earlier investigators, and are employed to show that the formula \( Q - A = T(\frac{C}{C'} - 1) \) is qualitatively correct in all four cases, and that for (1) and (3) it is capable of quantitative verification within the limits of experimental error. In the other two cases, the quantitative validity of the formula is only approximate.

The difficulty of determining the dissociation pressures of salt hydrates is discussed, and various forms of apparatus suitable for the determination are described. The sluggishness with which the maximum tension is reached is connected with the character of the efflorescing surface.

The theoretical and experimental work of Johnston (this vol., ii, 358) are adversely criticised. J. C. P.

Thermochemical Equivalence, and the Thermochemistry of Nitrogen. JOHN C. THOMLINSON (Chem. News, 1908, 98, 226. Compare Abstr., 1907, ii, 153).—In the belief that the numbers given previously may actually represent the thermal changes taking place, the author calculates from the structural formula he gives for nitrogen pentoxide and nitric acid an approximate heat of formation of 12,504 cal. and 45,447 cal. respectively. The experimental values are 13,000 cal. and 41,600 cal. J. V. E.

Apparent Deviations from Mariotte's Law and their Influence on the Measurement of Small Pressures. KARL SCHEEL and WILHELM HEUSE (Physikal. Zeitsh., 1908, 9, 784—789; Ber. deut. physikal. Ges., 1908, 6, 785—793).—The discrepancies
between the results of previous measurements of the compressibility of gases at low pressures have led the authors to examine the influence of a variation in the ratio of the exposed surface to the volume of the containing vessel in the case of air. In order to obtain a very large surface, one of the containing vessels was filled with about 20 grams of glass wool. For a variation in pressure from 0·07 to 0·7 mm. of mercury, \( pv \) remained constant in the absence of the glass wool, but when this was present, \( pv \) was found to diminish as the pressure was increased. After drying the glass wool by exhausting the apparatus, and leaving in contact for some time with phosphoric oxide, the variation in \( pv \) could no longer be observed.

The authors conclude that the deviations from Boyle’s law which Baly and Ramsay found when air was compressed at low pressures in capillary tubes are due to the presence of a film of condensed water on the surface of the glass containing vessels; when this is removed, the apparent deviations disappear, and the same results are obtained whether the gas is compressed in vessels with a small or with a large amount of exposed surface.

It is pointed out that when the McLeod gauge is used for the measurement of small pressures, all traces of water vapour must be removed from the gas and from the walls of the glass vessel.

H. M. D.

Viscosity and Fluidity. Eugene C. Bingham (Amer. Chem. J., 1908, 40, 277—280. Compare Abstr., 1906, ii, 218).—It is found with pure liquids that the fluidities of unassociated substances are approximately a linear function of the temperature, the relation being expressed by the formula \( t_1 = A\phi + K_1 \), where \( t \) is the temperature absolute, \( \phi \) the fluidity, and \( A \) and \( K_1 \) are constants. Associated compounds, however, especially the alcohols, depart widely from the linear type, except at high temperatures, when the fluidity curves approximate to a straight line. To represent the increase in temperature required to give the fluidity \( \phi \) on account of the association of the substance, use is made of the expression \( t_2 = K_2 - B/\phi \), where \( B \) and \( K_2 \) are constants. Added together, these two equations become \( t = t_1 + t_2 = A\phi - B/\phi + C \), which, when tested with Thorpe and Rodger’s data (Trans., 1897, 71, 374) for substances not highly associated, gives results in closer agreement with observed facts than does Slotte’s equation. With associated substances, such as acids, alcohols, and water, fairly close agreement is also observed. An approximate equation containing four constants, \( t = A\phi - B/(\phi + D) + C \), is also used; it gives with associated substances results in as close agreement with observed values as does the above simpler equation with unassociated substances. Tables comparing the values for hexane and water, calculated by the various equations, are given.

J. V. E.

Anomalies in the Viscosity of Emulsions and of Anisotropic Liquids. Emil Bose (Physikal. Zeitsch., 1908, 9, 707—708).—The changes observed in the viscosity of anisaldazine in the neighbourhood of the clearing point (this vol., ii, 258) cannot be used as a proof against the emulsion theory of anisotropic liquids. On the other
hand, Vorländer's experiments (this vol., i, 641) indicate that this theory is untenable. H. M. D.

Influence of Electrolytes on the Viscosity of Colloidal Liquids. MANFREDI ALBANESE (Arch. exp. Path. Pharm., Suppl., 1908, 16—28).—The viscosity of an aqueous solution of gum arabic is lowered (up to 30%) by the addition of electrolytes, but not by other substances. Solutions of certain other colloids, such as egg-albumin, are not affected by electrolytes, unless they have been dialysed previously, in which case the viscosity is somewhat diminished by adding salt. G. B.

Capillary Properties of Aqueous Solutions of Fatty Acids. BOHDAN VON SZYSZKOWSKI (Zeitsch. physikal. Chem., 1908, 64, 385—414. Compare this vol., ii, 827).—In contrast with the usually accepted view, the author finds that the heights to which water and fatty acid solutions rise in capillary tubes are almost independent of accidental impurities. For the purest water obtainable, for ordinary distilled water, for conductivity water, and for tap-water, the observed capillary rise is the same to within 0·1 mm. It is also found unnecessary to take special precautions in protecting the capillary tubes from dust; washing out with chromic acid mixture is quite adequate preliminary treatment.

The acids specially examined were n- and iso-butyric acids, n- and iso-valeric acids, and n- and iso-hexoic acids, and the experiments show that the higher an acid stands in the homologous series the greater is its effect in lowering the capillarity of water; the effects of the n- and iso-acids are nearly equal. In the case of iso-butyric acid, the variation in the capillarity with concentration is satisfactorily reproduced by the empirical formula \( y = 1 - \log(x/a + 1) \), where \( a \) and \( b \) are constants, \( x \) is the concentration, and \( y \) is the capillary rise referred to that of water as standard. The other acids examined obey this dilution law only approximately.

In most cases there are considerable differences between the author's measurements and those recorded by Drucker (Abstr., 1905, ii, 680); this is probably to be attributed to the different purity of the acids employed.

Some experiments made on the relative influence of iso-valeric acid and its barium salt, and on the effect produced by mixtures of the two, support the view that the depression of the capillarity of water is to be attributed to the undissociated part of the acid.

Experiments made with mixtures (1) of iso-butyric and iso-valeric acids, and (2) of iso-butyric and isohexoic acids, indicate that the depression of the capillarity of water is an additive property for the fatty acids. In the first case, this fact may be made the basis of an analytical determination of the mixed acids. J. C. P.

Osmotic Pressure. JOHANNES J. VAN LAAR (Zeitsch. physikal. Chem., 1908, 64, 629—632).—The formula for the osmotic pressure of a perfect solution proposed by Lewis (this vol., ii, 465) is identical with that obtained by the author (Abstr., 1895, ii, 107; 1906, ii,
526) on thermodynamic grounds. The formula obtained in this way is valid for imperfect, as well as for perfect, solutions, and is in accordance with the experimental results of Morse and Frazer (Abstr., 1905, ii, 475; 1906, ii, 600, 601). C. H. D.

The Vapour Pressure and Osmotic Pressure of a Volatile Solute. Hugh L. Callendar (Proc. Roy. Soc., 1908, A, 81, 335).—If an osmotic membrane is impermeable to the solute, the formula for the change of vapour pressure with hydrostatic pressure, and for osmotic pressure, are the same for a volatile as for a non-volatile solute. If, on the other hand, the membrane is permeable to the vapour, but not to the liquid phase, the equation depends on the concentration of the constituents in the vapour phase. C. H. D.

Osmotic Pressure of Sucrose Solutions at 15°. Harmon N. Morse and B. Mears (Amer. Chem. J., 1908, 40, 194—213. Compare Abstr., this vol., ii, 671).—In order to ascertain the cause of the osmotic pressure of sucrose solutions at 0° not being in agreement with the gas pressure, as at 20°, measurements at intermediate temperatures have been made. The authors now give results of measurements made at 15°, and from a comparison with those obtained at 0°, 5°, and 10°, previously recorded (loc. cit.), they are able to state that sucrose solutions exhibit a temperature-coefficient which is practical identical with the temperature-coefficient of gases.

Electric Osmosis. Joseph C. W. Frazer and Harmon N. Holmes (Amer. Chem. J., 1908, 40, 319—325).—A description is given of the apparatus used, and also the results of a preliminary investigation of the relative osmosis of a few salts of nitric acid at the concentration 0·001 N. The observations recorded for nine different salts appear to support the statement made previously (Abstr., 1906, ii, 600) that the osmosis of the nitrates of alkalies and alkaline earths varies inversely as the velocity of the cation divided by its valency, but the osmosis does not seem to be proportional to the specific resistance of the solutions.

It is suggested that some connexion may exist between this phenomenon and the results obtained by Kohlrausch (Abstr., 1903, ii, 403) and others working on the hydration of ions. J. V. E.

Improvement in Cells for the Measurement of Osmotic Pressure. Harmon N. Morse and B. Mears (Amer. Chem. J., 1908, 40, 266—277).—A detailed account is given of the weak points of the cell previously used and described (Abstr., 1905, ii, 575); the paper deals, however, in general with the form of cells and the method of closing them for the measurement of osmotic pressure. A new form of cell is described, which is entirely free from the objectionable features of the older one. The upper end of it is glazed inside and out, and has an accurately ground conical aperture at the top for the reception of a brass, cone-shaped collar, which is covered with a caoutchouc cap carrying the manometer.
tube. The closing of this cell is rapidly effected by screwing a brass nut down on to the collar. For details of construction and manipulation, the original must be consulted. J. V. E.

Improved Manometers for Measurement of Osmotic Pressure. Harmon N. Morse and B. F. Lovelace (Am. Chem. J., 1908, 40, 325—337).—An apparatus is described by means of which manometers may be compared with others, or with the standard, up to pressures of three hundred atmospheres. Corrections for meniscus, and a method of detecting a temporary or a permanent stretch of the manometer, are also given, as well as a detailed description of the method used by the authors for filling and closing their manometers.

J. V. E.

The System Water, and Sodium, Barium, and Copper Chlorides. Frans A. H. Schreinemakers and W. C. de Baat (Chem. Weekblad, 1908, 5, 801—806).—The authors represent the quaternary system water, sodium chloride, barium chloride, and copper chloride by means of a regular tetrahedron, the four angles giving the four components. The method is an extension of that employed to represent a ternary system by means of an equilateral triangle.

A. J. W.

Velocity of Reactions in Gases Moving through Heated Vessels, and the Effect of Convection and Diffusion. Irving Langmuir (J. Amer. Chem. Soc., 1908, 30, 1742—1754).—In studying the changes which take place in mixtures of gases while passing through hot tubes, the velocity coefficient of the reaction is usually calculated by means of the formula derived for reactions occurring in stationary gases. Bodenstein and Wolgast (this vol., ii, 162) have pointed out that this method is inaccurate, since allowance is not made for the mixing of the gases in the tube by diffusion or convection, and they have presented a formula which holds when the mixing of the gases can be considered complete.

In the present paper, these two formulae and the magnitude of the error arising from their application in various cases are considered. New formulae are developed, from which the velocity coefficient may be calculated in cases in which neither of the formulæ mentioned holds good, but in which, in the mixing of gases, diffusion plays a more important part than convection.

E. G.

Relation between the Velocity of Reaction and the Velocity of Stirring in Non-homogeneous Systems. K. Jablonski (Bull. Acad. Sci. Cracov, 1908, 620—631).—The rate of dissolution of a solid in a liquid increases with stirring. The connexion between the velocity constant for and the velocity of the stirrer $n$ is given by the empirical equation $k_1/k_2 = (n_1/n_2)^x$, where $x$ is a constant, the value of which varies with different apparatus, and even with the same apparatus if taken apart and put together again. This probably accounts for the different values of $x$ obtained by different investigators (Bruner and Tolloczko, Abstr., 1903, ii, 470; Bruner, Abstr., 1904, ii, 315; Sackur,
Abstr., 1906, ii, 261). The evaluation of $x$ is important, since it gives some information as to how far a reaction in a non-homogeneous system is dependent on diffusion (Noyes and Whitney, Abstr., 1897, ii, 479; Nernst, Abstr., 1904, ii, 315). In the same apparatus, so arranged that each experiment can be completed without any disturbance of the parts of the apparatus, the author has examined, at 25°, the solution of a marble plate in hydrochloric acid, the decomposition of hydrogen peroxide by platinised platinum foil, and the solution of a fused zinc plate in hydrochloric acid. The average values of $x$ are 0·93, 0·55, and 0·28 respectively. Hence the author deduces that, for the dissolution of a solid with a perfectly smooth surface, the velocity constant of the reaction is simply proportional to the velocity of stirring (as measured by the revolutions of the stirrer); if the surface of the solid is not smooth, the increase of the velocity constant is slower than the increase of the velocity of stirring, and the more so the rougher the surface.

C. S.

Saponification of Glycerides during Ester Exchanges in Homogeneous Systems. Robert Kremann (J. pr. Chem., 1908, [ii], 78, 364—367); Milan J. Stritar and Richard Fanto (ibid., 408).—Polemical (compare Abstr., 1907, i, 464; this vol., i, 120, 499; ii, 677).

Oxidations of Biological Importance. I. Hans Euler and Ivan Bolin (Zeitsch. physiol. Chem., 1908, 57, 80—98).—Careful experiments have been made on the oxidation of quinol by oxygen in the presence of manganous salts and alkali. It is shown that the velocity of the reaction is almost proportional to the pressure of the oxygen, and that the temperature-coefficient is very small between 0° and 40°. The solutions used were either neutral or slightly acid to phenolphthalein. To obtain such solutions, it is necessary to add dilute alkali, as quinol is decidedly acidic. The effect of the manganese (added as acetate) and of the sodium concentrations has been studied. As the whole reaction cannot be represented by means of the usual unimolecular formula, owing to the fact that part of the quinol is removed in the form of insoluble quinhydrone, the velocity has been determined by measuring the times required in the different experiments for absorbing a given volume (3 or 5 c.c.) of oxygen. The results show that in neutral or slightly acid solutions, manganese salts accelerate the oxidation, and that if the amount of sodium hydroxide added is the same, the rate of oxidation increases less rapidly than the manganese concentration. On the other hand, if the amount of manganese salt is constant, the velocity increases much more rapidly than the amount of alkali added.

The relationship between the effects of the manganese salt and the alkali is compared with that of an enzyme and co-enzyme.

Similar experiments have been made with "laccase" and manganese salts. It is shown that the laccase as prepared by Bertrand's method is slightly acid, and that it has no action on a quinol solution in the absence of manganese salts. It is obvious that the action of the laccase cannot be due to its alkaline nature, as suggested by Dony-
Hénault. Even the addition of 10 c.c. of 0·0001N hydrochloric acid to lucerne laccase does not affect the activity of the laccase in the presence of manganous salts.

It is further shown that the active principle of the laccase is not a substance of the enzyme type, as the preparations of laccase can be boiled for three minutes without destroying their activity in the least.

It is shown that salts of hydroxy-acids, for example, rochelle salt, sodium citrate, calcium gluconate, and sodium mucate, accelerate the oxidation of quinol in a marked manner when manganese salts are present, and it is suggested that laccase owes its activity to the presence of such salts.

J. J. S.

Some Oxydasic Phenomena Produced by Colloidal Ferrous Ferrocyanide. Jules Wolff (Compt. rend., 1908, 147, 745—747. Compare this vol., i, 137, 490; ii, 573).—In a feebly alkaline solution, colloidal ferrous ferrocyanide acts as an oxydase towards quinol. When a saturated solution of quinol is treated with ammonia to the extent of 1 part in 25,000, and colloidal ferrocyanide to the extent of 1 part of iron in 100,000, abundant crystals of quinhydrone are formed after twelve to fifteen minutes, oxidation being accelerated by shaking. The reaction is still observed with one-twenty-fifth as much iron if the quantity of alkali is increased to 1 part in 2000. Solutions of quinol treated with alkali alone become brown, but rarely deposit crystals, the colloidal iron alone has no action. If too much alkali (1%) is added, the solution is rapidly oxidised by the air, and no crystals are formed. These phenomena can be explained by the alkali facilitating the oxidation of the phenol, and consequently the action of the ferrocyanide, which thus acts as an oxydase. This view is supported by the facts that if the alkali is added some time before the colloidal iron, quinhydrone is no longer obtained, and that, other things being equal, the intensity of the reaction is proportional to the amount of alkali present (within the limits described above). From the latter observation, it would be expected that the alkali-earth oxides and hydrogen carbonates, and feebly alkaline salts, such as disodium hydrogen phosphate, would exercise a much less energetic action. This is actually found to be the case. The important part played by the alkali suggests that the oxidising action on quinol of certain manganese salts with weak acids discovered by Bertrand (Abstr., 1897, ii, 493) is due partly to their alkalinity, all of them being alkali to methyl-orange. The author finds that the addition to these solutions of a quantity of iron in the form of colloidal ferrocyanide, one-hundredth as great as that of manganese present, suffices to double the rate of oxidation of quinol, and that neutral aqueous manganese sulphate solutions, which are ordinarily almost inactive, increase their activity considerably when treated with traces of pyridine (which does not precipitate manganese).

E. H.

Catalysis. IX. Catalytic Reactions induced by Enzymes. Salomon F. Acree (J. Amer. Chem. Soc., 1908, 30, 1755—1760).—Attention is drawn to the work of Hudson (this vol., i, 605, 856)
on the inversion of sucrose by invertase, and it is shown that it
harmonises completely with the view already advanced by others, that
the addition of an enzyme to a reacting system brings about a catalytic
reaction, owing to the union of the enzyme with some constituent or
“substratum” of the reacting system to form a new product which
gives the same end-products as the substratum itself. It is pointed
out that this theory of catalysis through the formation of reactive
intermediate compounds renders the assumption of a vital energy for
such reactions unnecessary.

E. G.

Molecular State of Molten Salts. Richard Lorenz and Felix
Kaufler [in part, A. Liebmann] (Ber., 1908, 41, 3727—3738).—The
molecular weights of lead chloride, potassium nitrate, sodium nitrate,
and silver chloride in the fused state at various temperatures between
300° and 600° have been determined by measuring the surface tension
of the molten salt. The mean values of K obtained for potassium
nitrate and sodium nitrate, namely, 0·7 and 0·25 respectively, are in
fair agreement with those recorded by Bottomley (Trans., 1903, 83,
1421). The constants found for silver chloride and lead chloride were
respectively 0·8 and 0·9. Since these values are all less than 2·12,
the constant for liquids having a normal mol.-wt., the conclusion is
drawn that the salts investigated exist in the fused state in a highly
associated condition and that the ions are of a complex nature.

W. H. G.

Liquid Crystals. Otto Lehmann (Ber., 1908, 41, 3774—3783).—
Mainly a historical review of the author’s investigations on the subject
of liquid crystals.

The view recently put forward by Vorländer (this vol., i, 641), that
pseudo-isotropic, crystalline liquids are to be regarded as uniaxial
crystals, is combated. It is possible for a biaxial mass to become
pseudo-isotropic, that is, apparently uniaxial.

W. H. G.

The Liquid-crystalline State as a General Property of
Matter. P. P. von Weimarn (Zeitsch. Chem. Ind. Kolloide, 1908, 3,
166—168*).—Having shown in previous papers (this vol., ii, 90, 263)
that the colloidal-amorphous state of matter is a modification of the
crystalline, the author has now studied certain liquid crystals, such as
p-azoxyphenetole, both microscopically and ultramicroscopically, and
states his views of the nature of these crystals as follows. A liquid
crystal is a system of chemically or physically associated, solid, crystal-
line particles, between which vectorial forces of small tension act. The
small magnitude of the tension in the case of chemical association is
conditioned by the considerable energy expended in building up the
complicated molecule in the case of physical association by the
expenditure of energy requisite for the association of a number of
elementary crystalline particles to one particle.

G. S.

Theory of Colloids. Eduard Jordis (Zeitsch. Chem. Ind. Kolloide,
1908, 3, 153—166).—A summary of the author’s views on the nature
of colloidal solutions (compare Abstr., 1907, ii, 344; this vol., ii, 675).

The theory developed is in many respects identical with that of Duclaux (summarised in J. Chim. Phys., 1907, 5, 29), and many of Duclaux's results are discussed in detail. Pure hydrosols are not stable; the stability is determined by small amounts of other substances, usually electrolytes, which act as "sol-formers." These substances are in chemical combination with the dissolved colloids, and when they are completely removed, the hydrosol coagulates.

G. S.

Influence of Colloids on the Absorption of Gases, especially of Carbon Dioxide in Water. Alexander Findlay [with W. H. Habby] (Zeitsch. Chem. Ind. Kolloide, 1908, 3, 169—170).—The absorption of carbon dioxide by blood is not well understood, and it is suggested, in agreement with Wolfgang Ostwald (this vol., ii, 509), that, besides ordinary chemical combination, adsorption on the surface of the colloidal particles may be of importance in this connexion. As the first step in an investigation of the effect of colloids on the solubility of gases, the solubility of carbon dioxide in colloidal solutions of ferric hydroxide, gelatin, arsenic sulphide, silicic acid, albumin, dextrin, soluble starch, and glycogen has been measured at 25°. The first two colloids increase the solubility, the three last mentioned diminish it somewhat, and the other three are without effect.

G. S.

Colloidal Silver (Silver-gel) in Photographic Layers. Lüppo-Cramer (Zeitsch. Chem. Ind. Kolloide, 1908, 3, 170—174).—For the direct production of positives as employed in ferrotype photography, it is necessary that the silver in the parts which are most strongly lighted should be obtained in a more or less white form. This can now be effected with dry collodion plates covered with colloidal substances, such as tannin or gum.

In order to study the deposition of silver in different forms, silver bromide plates have been exposed in a Chapman Jones "plate tester," which allows of graduated illumination. When a plate thus exposed is developed with ferrous oxalate, the silver varies in appearance from greyish-white, on the most highly exposed parts, to greyish-black, on the parts almost in shade, and the difference persists after fixing. The white silver has a much smaller adsorptive power than the black form, and this difference in properties is employed to account for certain phenomena occurring in photographic processes.

G. S.

Freezing of Hydrosols. O. Bobertag, Karl Feist, and H. W. Fischer (Ber., 1908, 41, 3675—3679).—The paper gives a review of the behaviour of colloidal solutions at temperatures below the freezing point of the solvent. By rapid cooling to −70°, the metal is separated...
from Bredig’s colloidal suspension of platinum. By freezing a colloidal solution of arsenic trisulphide, Winter (Abstr., 1905, ii, 245) obtained the solid red modification, the authors cool a very dilute solution to $-70^\circ$ and, after thawing, recover the yellow colloidal solution, which, however, has become very turbid. Colloidal ferric hydroxide, cooled to $-70^\circ$ and thawed, remains clear, but shows a distinct augmentation of the Tyndall phenomenon. Aluminium acetate behaves somewhat similarly. The colloidal silver preparations, protargol, collargol, and lysargin, in the presence of albumin are dark coloured, very turbid, and optically non-homogeneous; by freezing, the silver collects into small lumps, which are distributed irregularly through the clear ice; on thawing, the solution is recovered apparently unchanged.

In connexion with organic colloids, certain dyes and substances of animal and vegetable origin have been examined. Rhodamine, chrysoidine, eosin, and safranine form true solutions; Nile-blue, acid-violet, methyl-violet, and magenta behave as semi-colloids, and night-blue, alkali-blue, Congo-red, and benzopurpurin as pronounced colloids (compare Freundlich and Neumann, this vol., ii, 820; Höber and Chassin, ibid., ii, 875).

On cooling a 10% solution of tannin, a considerable deposition is observed just above the freezing point; on thawing the frozen mass, the tannin partly dissolves, the remainder going into solution by slight warming. Haemoglobin (Merck), after being cooled to $-10^\circ$, $-70^\circ$, and $-180^\circ$, shows no apparent change. Solutions of gum or starch, cooled to the same temperatures and thawed, are quite turbid, but clarify by keeping. Dried albumin in solution, cooled to $-70^\circ$ to $-180^\circ$ and thawed, gives a turbid solution, which does not again clarify entirely. Solutions of gelatin, caragheen moss, agar-agar, and soap behave in a similar manner on freezing. The water is mostly frozen out from the jelly, so that the first portion of the liquid obtained by thawing is practically free from dissolved substances. After complete thawing, the product is decidedly non-homogeneous, consisting of a mobile liquid and a clotted jelly.

Attempting to explain the varying behaviour of the preceding colloidal solutions on freezing, the authors suggest that the freezing causes the colloidal particles to become aggregated, and that these aggregations may be partly or entirely destroyed by thawing, with the result that a precipitation or a solution is obtained.

C. S.

—From a study of the electrical conductivity and the ultramicroscopic state of solutions of various dyes (magenta, methylene-blue, crystal-violet, safranine, crystal-ponceau, naphthol-yellow S, Congo-red, etc.), the conclusion is drawn that dyes are dissociated in aqueous solution into two ions, and that some of them assume the colloidal condition. Addition of electrolytes favours the passage into the colloidal state. The authors' results do not entirely agree with those of Teague and Buxton (Abstr., 1907, ii, 933) and of Freundlich and Neumann (this vol., ii, 820).
Fixation of Different Derivatives of the Same Colouring Matter and Explanation of Dyeing. **Louis Pelet-Jolivet** and **N. Andersen** (*Compt. rend.*, 1908, 147, 808—810.* Compare preceding abstract).—Wool was placed in solutions containing equivalent quantities of derivatives of certain basic and acidic colouring matters. Other conditions being the same, the hydrochloride of safranine gave a paler tint than the sulphate, and the phosphate a darker tint. The hydroxide gave a tint intermediate between the sulphate and phosphate. The sodium salt of crystal-ponceau produced lighter tints than the magnesium salt; the aluminium salt gave darker tints, whilst the free acid was intermediate between the two latter salts in colouring power.

These experiments confirm the theory of Freundlich and Loser (Abstr., 1907, ii, 155, 534) of the fixation of basic and acidic dyes. The wool is supposed to become negatively charged when placed in water; when treated with a solution of the salt of a basic dye, adsorption of the positively charged organic ion occurs, whilst in the case of the salt of an acidic dye, the positive inorganic ion is adsorbed, causing the fabric to assume a positive charge, which, being smaller than the negative charge produced by an equivalent quantity of a negative dye, accounts for the well-known fact that wool and charcoal fix basic dyes more readily than acidic ones. This accords, moreover, with the effects produced by adding electrolytes to the bath, since positive multivalent ions or hydrogen ions should favour the fixation of the acidic dyes, whilst negative ions should hinder the process. A rational explanation is thus afforded of the action of mordants and of the tanning process.

**W. O. W.**

Passive State of Metals. Review of the Literature and Theories and Some Experiments on Cobalt, Iron, and Nickel. **Horace G. Byers** (*J. Amer. Chem. Soc.*, 1908, 30, 1718—1742).—A historical and theoretical discussion is given of the work done hitherto on the passivity of metals. Experiments are described which have been carried out with cobalt, iron, and nickel. A plate of the metal connected with a copper conducting wire was suspended as anode in a porous cup, which was placed in a porcelain beaker. Both beaker and cup were nearly filled with solutions of the various electrolytes. The cathodes, two platinum plates of the same size as the anode, were suspended in the beaker parallel to, and at equal distances from, the anode. The amount of the anode dissolved during the passage of the current was measured by its loss of weight.

The results obtained were so varied and conflicting as to render a brief summary impossible. Iron, nickel, and cobalt cannot be rendered passive by the hydrogen acids or their salts. Passivity may take place in electrolytes containing oxygen, and depends on the current density, the temperature, the electrolyte, and the treatment of the metal. The metals may be either passive or active under exactly the same current conditions so long as the current density is below a critical value.

The phenomena of passivity have not yet received any satisfactory explanation. Faraday's view, connecting passivity with the formation of a coating of oxide on the metal, is untenable. The hypotheses of

Finkelstein and Müller, according to which the passive state is occasioned by changes in the valency of the metal, are unsatisfactory. Many of the results now obtained cannot be reconciled with Fredenhagen’s explanation, which attributes passivity to anodic oxygen or an oxygen alloy.

E. G.

Determination of the Atomic Weight of the Simple Ponderable Substance, Pantogen. Gustave D. Hinrichs (Compt. rend., 1908, 147, 797—800. Compare this vol., ii, 573, 574).—The author assumes the existence of a simple fundamental material of atomic weight 1/128, and thence proceeds to theoretical deductions as to the weight and geometrical forms of the atoms of hydrogen, helium, nitrogen, oxygen, and fluorine. The paper includes a diagrammatic representation of the atoms of these elements, and of their physical properties in the neighbourhood of the absolute zero.

H. O. W.

Atomic Weight of Radium and Other Elementary Substances. Henry Wilde (Phil. Mag., 1908, [vi], 16, 824—830. Compare Abstr., 1907, ii, 149; this vol., ii, 141).—The author still maintains that the true atomic weight of radium is 184. A periodic table is given, based on the numerical relationships previously described.

H. M. D.

New Form of Test-tube Holder. H. Stoltzenberg (Zeitsch. angew. Chem., 1908, 21, 2272).—The advantage of the new form of wire holder described lies in the fact that, not only may the tube or other object held be readily released, but the force by which it is held may be increased by the power of the hand. It thus becomes possible to lift fairly heavy vessels and to shake them without fear of their falling.

J. V. E.

Apparatus for Evaporating in a Dish under Reduced Pressure. Eduard Donath (Chem. Zeit., 1908, 32, 1107).—The accompanying figure depicts the apparatus described by the author. It consists of two parts, A and B, both being made of stout copper having thick, broad flanges so as to form an air-tight chamber when they are screwed down on to an asbestos washer by screws, g. Into the lower part, A, the evaporating basin, f, is placed upon asbestos fibre. The upper part, B, is perforated in three places, c, d, and e; c is covered by a thick plate of transparent mica, the liquid to be evaporated is introduced through d, and e is connected to an exhaust pump.

J. V. E.
Circulating Pump. H. Stoltzenberg (Zeitsch. angew. Chem., 1908, 21, 2271—2272).—A new form of small centrifugal pump is described as being an efficient circulator of liquid from a thermostat through condensers, jacketed polarimeter tubes, etc. The power required to drive the pump is very small, and when rotating at 1200 revolutions per min. it is able to lift water to a height of ten metres.

J. V. E.

Inorganic Chemistry.

[Production of Hydrogen Peroxide from Persulphuric Acid.] Consortium für Elektrochemische Industrie (D.R.-P. 199958).—When carefully-purified solutions of persulphuric acid are treated with sulphuric acid (D 1.4) at 50—80°, the former rapidly yields hydrogen peroxide with a loss of only 3 or 5% of oxygen. This result is, however, only obtained in the absence of all impurities likely to decompose hydrogen peroxide catalytically (compare Trans., 1904, 85, 1526—1533).

G. T. M.

Generation of Oxygen in a Kipp’s Apparatus. Ludwig Wolter (Chem. Zeit., 1908, 32, 1066).—The extremely vigorous evolution of oxygen from alkali peroxides when treated with water or dilute acids has been sufficiently modified by admixture with indifferent substances to allow of the generation of the gas in a Kipp’s or other gas generation apparatus by this method.

The best results have been obtained with a substance prepared by adding a mixture of 100 parts of sodium peroxide and 25 parts of magnesium oxide to 100 parts of molten potassium nitrate. This, when solidified and broken into pieces of a suitable size, is placed in a Kipp’s apparatus and treated with dilute hydrogen chloride. The substance may be kept for some time ready for use by dipping the lumps into molten paraffin wax so as to protect them from the atmosphere.

J. V. E.

Dynamic Allotropy of Sulphur. I. Hugo R. Kruyt (Zeitsch. physikal. Chem., 1908, 64, 513—561).—The investigations of Smith and his collaborators (Abstr., 1903, ii, 139, 284; 1905, ii, 382, 580; 1906, ii, 157; 1907, ii, 20; this vol., ii, 32) have led to results which accord best with the theory that $S\lambda$ and $S\mu$ are partly miscible in the liquid state, but that the equilibrium curve lies entirely outside the heterogeneous region. Smith’s conclusion, that the equilibrium curve cuts the curve of miscibility, is untenable. A bibliography and review of previous literature on the subject are given.

The melting point of rhombic sulphur was determined by immersing capillary tubes containing the powdered sulphur in boiling calcium chloride baths at different temperatures, and was finally fixed at
112.4°. Similar sulphur, heated for an hour at 90° in ammonia to produce equilibrium, melted at 110.9°. The unstable “natural melting point” of rhombic sulphur was then found graphically to be 110.5°, and the melting point of pure rhombic sulphur 112.8°. From 111° onwards, the melting-point curve must be parallel to the concentration axis.

The composition of the vapour in contact with liquid sulphur at different temperatures was measured by blowing a current of air through the molten sulphur at constant temperature, and condensing the current of vapour on the surface of water at 0°. Ammonia gas was introduced as a catalyst, this being subsequently removed by the current of air, the sulphur dioxide formed by partial oxidation then serving to preserve the composition of the vapour unchanged during cooling. The condensed sulphur was analysed by extraction with carbon disulphide. The vapour and liquid curves intersect at 324° and 24.7% Sμ.

The vapour-pressure curve of the system Sμ—Sμ presents either a maximum or a minimum, but it is not yet possible to determine which. This point is to be further investigated. This curve must cut the curve of equilibrium.

C. H. D.

The Boiling Point of Sulphur on the Constant Pressure Air Thermometer. NICHOLAS EUMORFOPoulos (Proc. Roy. Soc., 1908, A, 81, 339—362).—A detailed account of measurements with a Callendar air thermometer of Jena glass. The various sources of experimental error were very fully investigated, the most important being the changes of volume of the glass bulbs. The mean value of the boiling point of sulphur obtained is 443.5°. C. H. D.

The Boiling Point of Sulphur. HUGH L. CALLENDAR (Proc. Roy. Soc., 1908, A, 81, 363—366. Compare preceding abstract).—The changes of volume in glass render it an unsuitable material for accurate thermometry. The value for the boiling point of sulphur obtained by Eumorfopoulos is in close agreement with those obtained by other methods, the chief source of error being now the uncertainty as to the true coefficient of expansion of mercury. C. H. D.

Preparation of Hydrazine. FRITZ RASCHIG (D.R.-P. 198307).—When excess of strong aqueous ammonia reacts with a solution of sodium hypochlorite in the presence of an organic substance to increase the viscosity of the solution, a good yield of hydrazine is obtained. One litre of sodium hypochlorite and 12 c.c. of a solution containing 5% of joiners’ glue are added to 3 litres of concentrated aqueous ammonia, the solution heated to drive off ammonia, and concentrated to the crystallising point, when 80—90 grams of hydrazine sulphate are obtained on the addition of sulphuric acid. The product is purified by crystallisation. G. T. M.

Hydroxylamine. I. ERICH EBELL and E. SCHOTT (J. pr. Chem., 1908, [ii], 78, 289—342).—The authors review the various formulae
which have been proposed for hydroxylamine, and assemble the evidence in favour of the view that it is a tautomeric substance, having in alkaline solution the constitution \( \text{NH}_2\cdot\text{OH} \), and acting as an acid, but in acid solution behaving as an oxonium base, \( \text{NH}_3\cdot\text{O} \), forming salts of the type \( \text{NH}_3\cdot\text{O}<\text{H}^+ \). This view of the nature of hydroxylamine is applied to the explanation of its properties and of the reactions which it undergoes.

Anhydrous hydroxylamine is readily prepared by dissolving 4—5 grams of the 75% distillate obtained by Uhlenhuth's method (Abstr., 1900, ii, 475) in 100—400 c.c. of absolute alcohol, and cooling the solution to about \(-18^\circ\). Hydroxylamine is deposited from the stronger solutions in white leaflets, and from the more dilute solutions slowly in needles.

Lobry de Bruyn found (Abstr., 1892, 1391) that hydroxylamine reacts with zinc, forming zinc oxide and ammonia. It is now shown that the intermediate product of this reaction is a zinc salt, \( \text{Zn(O-NH}_2)\_2 \), and not an additive compound, \( \text{Zn(O-NH}_3) \). A similar calcium salt has been prepared, and indications obtained of the existence of an extremely unstable ferric salt. It is proposed to apply the term hydroxylamites to the salts \( \text{NH}_2\cdot\text{OM}', \text{(NH}_2\cdot\text{O)}_2\text{M}'' \), etc.

**Calcium hydroxylamite**, \( \text{Ca(O-NH}_2)\_2 \), is formed with evolution of gas when calcium filings are treated with anhydrous hydroxylamine at \( 50^\circ \). Ammonia is evolved only if heat is developed, which takes place if water is present. The white salt, which separates towards the end of the reaction, is extremely explosive, being much more dangerous than anhydrous hydroxylamine; when washed with absolute alcohol and dried in a vacuum over sulphuric acid, it is obtained as a white, amorphous powder, which detonates at \( 180^\circ \), and is hydrolysed by water, slowly by moist air, forming calcium hydroxide and hydroxylamine. It is considered that Hofmann and Kohlschütter's calcium salt of hydroxylamine (Abstr., 1898, ii, 380) is a mixture of calcium hydroxylamite and calcium hydroxide.

**Zinc hydroxylamite**, \( \text{Zn(O-NH}_2)\_2,3\text{NH}_3\cdot\text{O} \), prepared by the action of anhydrous hydroxylamine on finely-divided pure zinc and treatment of the product with absolute alcohol, is obtained in glistening crystals, loses hydroxylamine, and leaves a residue of zinc oxide when gradually heated, detonates, evolving ammonia, when quickly heated, and is readily hydrolysed by moisture, forming zinc hydroxide.

Haber observed (Abstr., 1898, ii, 23) that hydroxylamine oxidises ferrous salts in ammoniacal or sodium carbonate solution, and stated that the hydroxylamine is itself converted into ammonia. It is now found that under these conditions nitrogen and nitrous oxide are first evolved, ammonia appearing only towards the end of the reaction. The study of the reaction is complicated by the fact that hydroxylamine is decomposed catalytically by ferric hydroxide in neutral or alkaline solution, yielding the same three products. The ferric hydroxide residue is scarlet, becomes brownish-red when heated, does not decolorise permanganate or evolve chlorine from hydrochloric acid, and thus resembles the ferric hydroxide residue obtained from the catalytic
decomposition of hydrogen peroxide. If hydroxylamine is treated with ferric hydroxide in absolute alcoholic solution at about -18°C, a brown precipitate is formed, which, after being washed with absolute alcohol, decomposes on treatment with water, forming nitrogen, nitrous oxide, and ammonia, and must therefore contain ferric hydroxylamite.

Hydroxylamine silicofluoride, \((\text{NH}_3\text{O})_2\cdot \text{H}_2\text{SiF}_6\cdot 2\text{H}_2\text{O}\), prepared by adding 16% aqueous hydrofluosilicic acid to a 25% aqueous solution of hydroxylamine and allowing the mixture to evaporate, crystallises from boiling methyl alcohol in scales, and is almost insoluble in alcohol, but readily dissolves in water.

Hydroxylamine titanofluoride, \((\text{NH}_3\text{O})_2\cdot \text{H}_2\text{TiF}_6\), prepared by adding 20% hydroxylamine to a cooled solution of hydrofluotitanic acid and evaporating the solution in a vacuum, separates from methyl alcohol in white crystals. With quadrivalent titanium, hydroxylamine gives the same yellow coloration, caused by the formation of a higher oxide of titanium, as is produced by hydrogen peroxide.

The Interaction of Nitrous Gases and Oxygen with Water.

Fritz Foerster and M. Koch (Zeitsch. angew. Chem., 1908, 21, 2209-2219. Compare this vol., ii, 941).—In continuation of this investigation (loc. cit.), the authors have studied the behaviour towards water of nitric peroxide when greatly diluted with air. The results, which are tabulated, show the proportion of nitric peroxide converted into nitric acid to be greater when the concentration of this gas in the gaseous mixture is greater; it is, however, not directly proportional, being considerably less than would be expected. This may be explained by the fact that with large excess of air the nitrous acid represented in the equation \(\text{H}_2\text{O} + 2\text{NO}_2 \rightarrow \text{HNO}_3 + \text{HNO}_2\), being less stable in solution, allows of a more rapid absorption of fresh nitric peroxide than when the excess of air is less. It is also shown that with diluted nitric oxide the increased concentration of nitric acid is not due simply to absorption of more oxides of nitrogen, but, in part, to the nitric acid formed previously leaving the solution with water as \(\text{HNO}_3\cdot \text{H}_2\text{O}\). The limiting concentration at the ordinary temperature at which this takes place is indicated by the following: with 1% \(\text{NO}_2\), about 46% \(\text{HNO}_3\); with 2% \(\text{NO}_2\), about 51.8% \(\text{HNO}_3\), and with 5% \(\text{NO}_2\), more than 55.6%.

From a study of the influence of a large excess of air on the behaviour of the nitrous acid produced in the primary change, it is shown that it completely decomposes, with time, into nitric acid and nitric oxide. Excess of oxygen, when not at the same time under a smaller partial pressure, rapidly oxidises this nitric oxide to nitric peroxide, but, in the case of a large excess of air, there is insufficient time for the nitric oxide that is carried forward from the water solution to be completely oxidised to the peroxide. The quantity of nitric oxide escaping oxidation was ascertained by substituting for the water, dilute alkali hydroxide solution as absorbent, and the quantity of nitrite produced is shown to be greater when the dilution by air is greater.

Nitric peroxide, even when largely diluted by air, is rapidly
oxidised by ozone to nitrogen pentoxide, and when such a gaseous mixture is passed into water, or aqueous nitric acid, an acid solution containing more than 80% HNO₃ may readily be obtained.

J. V. E.

Formation of Colloidal Phosphorus. Alfred Lottermoser (J. pr. Chem., 1908, [ii], 78, 367—368).—When exposed to diffused daylight in a closed vessel, a clear, colourless solution of white phosphorus in contact with solid white phosphorus gradually becomes opalescent and orange-yellow by reflected, but clear and yellowish-red by transmitted, light. The hydrosol thus formed is unstable, and, after some time, deposits a scarlet crust of red phosphorus on the glass walls of the vessel. The formation of the hydrosol must result from the conversion, under the influence of the diffused light, of the dissolved white phosphorus into the red modification, which is almost insoluble in ether, and separates, therefore, at first in the colloidal form. The strong yellow colour of the hydrosol supplies further evidence that the light red colour of the red phosphorus depends on the finely-divided state of the latter. So soon as red phosphorus is deposited on the walls of the vessel, the solution is free from the hydrosol, partly because the colloid is completely precipitated and partly because the deposit protects the remaining white phosphorus from the action of light.

G. Y.

Ionisation by Phosphorus and Phosphorescence. Léon Bloch and Eugène Bloch (Compt. rend., 1908, 147, 842—844).—It has been shown previously (Abstr., 1905, ii, 72) that the air which has passed over phosphorus is the seat of a true ionisation, and the ions produced have a small mobility. It is now found that when an air current of greater velocity is employed, the phosphorescence becomes elongated in the direction of the current, and with a further increase in the velocity, definitely separates itself from the phosphorus with the production of a dark space. The phosphorus generally retains a slight phosphorescence, but this disappears finally when the velocity is sufficiently augmented. If the tube is sufficiently long, the phosphorescence which assumes the form of a phosphorescent column can be removed several metres from the phosphorus by regulating the air-current. A condenser placed in or beyond, but not before, the phosphorescence becomes charged, whilst an iodide-starch paper (test for ozone) becomes blue in the positions in which the condenser is charged. It is thus shown that the phosphorescence, ionisation, and ozone are produced in the same region, and therefore that the three phenomena are produced, not by the oxidation of the phosphorus itself, but of some substance emanating from it. This might be either phosphorus vapour or phosphorous oxide. From the results obtained by Jungfleisch (Abstr., 1905, ii, 244) and by Schenk, Mihr, and Banthien (Abstr., 1906, ii, 326), the latter supposition seems the more probable. This view is also supported by the observation of the authors, that if the dark space is cut suddenly, phosphorescent bubbles are formed, which travel slowly in opposite directions, disappearing either on collision or, more rarely, of their own accord.
If the dark space contains phosphorous oxide, which is spontaneously inflammable, this phenomenon is explained, the movement of the luminous bubbles being the propagation of explosive waves.

The transformation of phosphorus into phosphoric oxide is a vivid combustion, and it is therefore to be expected that the ions produced would be of the same nature as in other cases of combustion. The analogy between the large ions of phosphorus and those of the gases of flames has been pointed out by Bloch and by Harms (Abstr., 1904, ii, 331), who finds an increase in the mobilities as the phosphorus is approached. The latter result is confirmed by the authors, who obtain values up to 0.1 mm. close to the phosphorus. The mobilities can, however, be greatly increased (up to 2—3 mm.) by inserting a cotton plug beyond the phosphorus to retain the fumes formed on the latter. It seems, therefore, that the phosphorus ions are produced by the combustion of the phosphorous oxide, and rapidly rendered heavy by the presence of liquid or solid particles.

E. H.

Sublimation of Arsenic. W. P. A. Jonker (Chem. Weekblad, 1908, 5, 783—785).—The sublimation point of arsenic determined by the aid of a thermopile is 616°/760 mm.

A. J. W.

The Luminosity of the Bunsen Flame. Burritt S. Lacy (Zeitsch. physikal. Chem., 1908, 64, 633—640. Compare Haber and Richardt, Abstr., 1904, ii, 166).—In order to study the cause of the luminosity in the inner zone, the author has introduced methane into a separated Bunsen flame, 5 mm. above the summit of the inner cone, without producing any effect on the luminosity. Special experiments were made to eliminate the cooling effect of the current of methane. The results are in accordance with Haber and Richardt's view, that the production of the light is a luminescence phenomenon. The presence of methane in the middle zone of the separated flame was confirmed.

The constant \( k = [\text{H}_2\text{O}] [\text{CO}] / [\text{CO}_2] [\text{H}_2] \) was found to be the same whether the gases were taken from a zone just above the green cone or from a higher zone at a temperature 300° lower, being about 3.7. A catalytic influence of the platinum tube used was, however, observed.

C. H. D.

Precipitated Silica. Henry Le Chatelier (Compt. rend., 1908, 147, 660—662).—The existence of hydrates of silica is questioned on account of the variable amounts of water revealed by analysis. When gelatinous silica, purified from electrolytes by diffusion, was heated in a sealed tube at 320° for six hours, no change in appearance or consistency could be detected. The author draws the conclusion that silica, like chromium trioxide, does not form hydrates, but on account of its absolute insolubility remains in an extremely fine state of division when precipitated. Freshly-precipitated gelatinous silica in distilled water may be used to polish hard substances, such as bronze.

R. J. C.
Products of the Arc and Spark Electric Discharge in Liquid Argon. Franz Fischer and George Iliovici (Ber., 1908, 41, 3802—3810).—If compounds of argon are capable of existence, they are probably endothermic, and might be produced at a high temperature and afterwards be preserved by sudden cooling, as in the formation of ozone in liquid oxygen (compare Abstr., 1907, ii, 163, 340). Cadmium was used for the electrodes, and with the spark discharge, after three hours in liquid argon, 3·3 mg. of an olive-green substance, and with the arc after 140 minutes, 22·7 mg. of a black substance, were obtained. These, on examination, proved to contain cadmium nitride, but mixed with cadmium in the case of the arc product. The spectrum of the gas obtained by heating these substances in a vacuum showed the lines of nitrogen, hydrogen, cadmium, and mercury, with some lines of argon, and the gas obtained by the action of phosphoric acid on the substance gave hydrogen, mercury, and argon lines—nitrogen could not be detected, but the product after the action contained ammonia. The nitrogen must have been derived from small traces of air in the argon used.

The spectroscopic examination was carried out in tubes fitted with aluminium electrodes, previously heated at 150° to expel gases. The tube gradually became "hard," and the nitrogen spectrum disappeared, leaving only the argon and hydrogen lines. This behaviour of the spectrum tube makes the source of the argon uncertain, as it is in very small quantities. The conclusion is drawn provisionally that the argon is absorbed by the nitride.

Electrolytic Soda Industry. Theory of the Bell-chamber Process. André Brochet (Compt. rend., 1908, 147, 674—676).—The salt solution undergoing electrolysis flows through the apparatus from cathode to anode. If the velocity of the liquid is equal or superior to that of the OH⁻ ions, the yield should be theoretical. The velocity of the OH⁻ ion varies directly as the ionic mobility and current density, and inversely as the conductivity. When the layer of liquid containing only OH⁻ anions remains stationary, the concentration of the caustic alkali leaving the apparatus varies directly as the conductivity and inversely as the ionic mobility, but is independent of current density and the nature of the cation. It follows that solutions of potassium chloride give a stronger alkali than common brine. Temperature has no influence on the strength of alkali obtained, but a high temperature economises current.

Transparent Silver and other Metallic Films. Thomas Turner (Proc. Roy. Soc., 1908, A, 81, 301—310. Compare Beilby, Abstr., 1904, ii, 647).—The investigations of Faraday on the conditions of formation of transparent metallic films have been extended. Gold leaf does not undergo any change at 500°, but rapidly becomes transparent at 550°, microscopic examination showing that the originally translucent film has become aggregated to opaque masses, leaving clear spaces between them. Soft gold, which has not
been mechanically strained, does not show this sudden change of properties.

Silver foil becomes slightly transparent in air at 240°, and more rapidly at higher temperatures. Heating to 500° in hydrogen or in charcoal powder does not produce transparency, whilst the effect on gold is independent of the surrounding gas. The presence of oxygen is necessary for the change in silver, although the quantity of oxygen absorbed is very minute. The particles of aggregated silver are smaller and less opaque than those of gold.

Copper undergoes a similar change, but much transparent oxide is formed. This is the origin of the coloured surface films obtained on oxidising copper. Aluminium and alloys of copper and zinc do not become transparent when heated.

C. H. D.

The True Atomic Weight of Silver according to Stas's Experiments. Louis Dubreuil (Compt. rend., 1908, 147, 856—859).—It has been shown previously (this vol., ii, 936) that it is generally impossible to deduce the true value of an atomic weight from the measurement of a single analytical ratio, and that the method of least squares enables the most probable value for the atomic weights in question to be determined in each experiment. Comparison of the values so obtained for the same element gives the means of determining the true atomic weight, and the result is the more probable the greater the number of methods employed. The author has applied this method of calculation to the values obtained by Stas for the analytical ratios of AgCl, I, AgI, Ag₂S, KCl, NH₄Cl, NaCl, LiCl, KBr, NaBr, NH₄Br, AgNO₃, and Ag₂SO₄ compared with Ag, and for the ratios KCl/AgNO₃, NH₄Cl/AgNO₃, AgCl/AgClO₃, AgBr/AgBrO₃, and AgI/AgIO₃, and, as a general mean of them all, has obtained the value 107.9921 for the atomic weight of silver, the extreme values of the series being 108.0313, obtained from the ratio AgI/Ag, and 107.9449, for the ratio KBr/Ag.

Taking into consideration the fact that all the results employed are taken from the work of one experimenter, the conclusion is drawn that silver has the atomic weight 108.

E. H.

Alloys of Silicon and Silver. G. Arrivaut (Compt. rend., 1908, 147, 859—861).—Wöhler (Ann. Chim. Phys., 1858, [iii], 54, 222), Warren (Abstr., 1889, 1125; 1893, ii, 474), and de Chalmot (Abstr., 1896, ii, 362) have obtained substances which they considered to be silver silicides, whereas Percy, Moissan (Abstr., 1896, ii, 173; 1904, ii, 560), and Vigoureux (Abstr., 1907, ii, 543) have repeatedly stated that silver and silicon do not combine. In view of this divergence of opinion, the author has examined mixtures of silver and silicon by Tammann's thermal method. The results are given in a table and in the form of curves.

Examination of the latter shows that the liquidus consists of two branches starting from the melting points of silver (950°) and silicon (1415°) respectively, and intersecting at about 800° in a point corresponding with about 5% of silicon. The solidus consists simply of a horizontal line passing through the eutectic point and extending
from 0% to 90% of silicon; thus silver and silicon do not give any point of combination. Consideration of the periods of eutectic crystallisation suggests the existence of mixed crystals of silicon and silver, but this is not confirmed by analysis. In the fusions containing 40—60% of silicon, a small, white pearl is observed on the bluish-grey button of slightly oxidised silicon. This is formed probably owing to the increase in volume of the silicon on solidification. It contains 4·8% of silicon and 94·85% of silver. E. H.

Silver Sub-halides. A. P. H. Trivelli (Zeitsch. wiss. Photograph. Photophysik. Photochem., 1908, 6, 358—372).—A critical comparison of the two chief theories regarding the nature of the silver sub-halides. It is shown that the phenomena, which are usually cited in support of the view that the sub-halide is an adsorption compound of colloidal silver and silver halide, can be explained equally satisfactorily in terms of the theory that the sub-halide is a molecular compound. In certain cases, the molecular theory accounts for the observed facts more satisfactorily than the adsorption theory.

In an appendix, it is pointed out that the reducing action of ammonium persulphate can be explained more simply in terms of the molecular theory than by the adsorption hypothesis. The denser portions of the developed image contain more silver and silver sub-halide and less silver halide than the less dense regions. A sodium thiosulphate solution will, in consequence, be more quickly saturated with silver thiosulphate in the less dense parts of the image. In the denser regions, the greater concentration of unchanged sodium thiosulphate will cause the sub-halide to be decomposed to a greater extent, and the resulting greater concentration of free silver is the cause of the more energetic action of the ammonium persulphate.

H. M. D.

Reaction between Silver Sulphide and Silver Sulphate. Production of a Dark-coloured Glass. Otto Sackur (Ber., 1908, 41, 3356—3359).—Experiments to determine the dissociation pressure of the system $\text{Ag}_2\text{S} + \text{Ag}_2\text{SO}_4 = 4\text{Ag} + 2\text{SO}_2$ were unsuccessful, as, although a constant pressure was obtainable after heating at a constant temperature (above 300°) for some days, repetition of the experiment gave different values. The pressure at 300° is above 10 atmospheres.

When heated in Thüringian glass, the mixture imparts to the glass surface, below 400°, after some time a reddish-brown colour, which absorbs the actinic rays of the spectrum. Such a glass contains several per cent. of silver.

W. R.

Preparation and Composition of the Hydrogen Carbonates of Calcium and Barium. Edward H. Keiser and Sherman Leavitt (J. Amer. Chem. Soc., 1908, 30, 1711—1714).—Experiments are described which show that calcium hydrogen carbonate is precipitated when potassium or ammonium hydrogen carbonate is added to a solution of calcium chloride at 0°, and that the salt can be separated and analysed if the temperature is not allowed to rise above 1° or 2°. Even at this temperature, the compound slowly decomposes. The results of analysis point to the formula $\text{CaCO}_3\cdot 1·75\text{H}_2\text{CO}_3$. 

E. H.
Barium hydrogen carbonate can be obtained similarly by the action of ammonium hydrogen carbonate on barium chloride solution at 0°, but it undergoes gradual decomposition, and is therefore difficult to analyse.

E. G.

Composition of the Hydrogen Carbonates of Calcium and Barium. Edward H. Keiser and LeRoy McMaster (J. Amer. Chem. Soc., 1908, 30, 1714—1718).—Calcium and barium hydrogen carbonates were prepared in the manner described by Keiser and Leavitt (preceding abstract), except that precipitation was effected in a solution containing gelatin in order to retard decomposition. Analysis was effected by determining the ratio of carbon dioxide to calcium or barium oxide. The results show that the calcium salt has the composition CaCO$_3$1.8H$_2$CO$_3$, and the barium salt the composition BaCO$_3$1.5H$_2$CO$_3$.

E. G.

Preparation of Calcium, Strontium, and Barium Silicides. Th. Goldschmidt (D.R.-P. 199193).—Calcium silicide may be produced by heating in an ordinary furnace a mixture of silicon and calcium oxide, the reaction being facilitated by the addition of some calcium fluoride and chloride. The interaction takes place as follows: 5CaO + 5Si = 2CaSi$_2$ + 3CaO$_2$SiO$_2$. A similar change occurs with the oxides of the other alkaline earths.

T. G. M.

Zinc Phosphides. Pierre Jolibois (Compt. rend., 1908, 147, 801—803).—Zinc and phosphorus were heated together in a crucible until phosphorus vapour ceased to be evolved. The product was freed from excess of zinc either by ignition in a vacuum at 600° or by treatment with mercury or fuming nitric acid. The residual phosphide, Zn$_3$P$_2$, is identical with that described by Vigier (Bull. Soc. chim., 1861, 3, 5), and forms octahedral crystals, D$_{15}$ 4.55, which dissolve readily in hydrochloric acid, giving pure phosphine.

The preparation of the phosphide, Zn$_3$P$_2$, from its elements is also described. This phosphide is non-crystalline, and has D$_{15}$ 2.97; at 400°, it undergoes dissociation into phosphorus and Zn$_3$P$_2$.

W. O. W.

Sulphides of the Rare Earths. I. Cerium Sulphides and their Limits of Existence. Wilhelm Biltz (Ber., 1908, 41, 3341—3350. Compare Sterba, Abstr., 1904, ii, 662).—Cerium disulphide, Ce$_2$S$_4$, is prepared by heating cerium sulphide in a current of hydrogen sulphide at 580—600°, the experiment being controlled by weighing from time to time; 2 to 3 grams require twenty hours for complete conversion. It forms a dark yellowish-brown, crystalline powder, moderately stable in air and cold water. An oxygenated product, Ce$_2$S$_2$O$_4$, has also been obtained, and as this is of approximately the same weight as the disulphide, a complete analysis is necessary in characterising the compound. Hydrochloric acid (17.7%) dissolves the disulphide in the cold, an odour of hydrogen persulphide is noticed, and afterwards sulphur is precipitated. This is held to prove that the disulphide is not a true analogue of the dioxide, but a
polysulphide, Ce$_2$S$_3$S. The related lanthanum disulphide, La$_2$S$_3$S, is
dark yellow, and also gives hydrogen persulphide under similar
conditions.

The red sesquisulphide, Ce$_2$S$_3$ (Muthmann and Stützel, Abstr.,
1900, ii, 142), is obtained on heating the disulphide or the sulphate in
a current of hydrogen sulphide at 750—800°.

The conversion of the disulphide into the sesquisulphide has been
examined up to 1200°. The temperature of decomposition is about
720°; the lower sulphide is stable at a red heat, and does not react
with hydrogen or nitrogen at that temperature, but between 1400°
and 1500° it melts and decomposes. The sesquisulphide prepared at
745°; when heated in a current of hydrogen sulphide for thirty hours
at 615°, did not re-absorb sulphur. This irreversibility is only
apparent, as by heating the disulphide in a current of hydrogen at
400° the sesquisulphide was obtained, and this product re-absorbed
4.2% sulphur.

The heat of solution of the disulphide, CeS$_2$, in hydrochloric acid is
32,500 cal.; that of CeS$_{1.5}$, 37,800 cal. (39,500 cal. from product pre-
pared at 400°). From these figures, the equation 4CeS$_2$ = 2Ce$_2$S$_3$ +
2S(amorp.) = 18,600 cal. is calculated.

By the use of Nernst’s equation for heterogeneous equilibria, the
decomposition temperature is calculated to be 793°, whereas that
found was roughly 720°.

W. R.

Eutectics. I. The Alloys of Lead and Tin. Walter
Rosenhain with P. A. Tucker (Phil. Trans., 1908, A, 209,
89—122).—Alloys of pure lead and pure tin have been studied by
thermal and microscopic methods, the curves of ordinary cooling and
of differential cooling being taken. The eutectic point is at 62.93% of
lead and 180°. Lead forms solid solutions with from 0 to 16% Sn
at 180°. Former observers have found the presence of eutectic in
alloys containing much less tin, and this is shown to be due to the
slowness with which diffusion takes place in the solid alloys. Heating
at 175° for six weeks was found to be necessary to bring about
equilibrium. On the other hand, tin does not form solid solutions
with small quantities of lead.

Alloys containing from 18 to 63% of tin undergo a change,
accompanied by development of heat, on cooling to 149°. In alloys
containing from 8 to 18% Sn, the transformation takes place at lower
temperatures, the passage of the solid solution from the β- to the α-
form involving the rejection of a part of the tin. The alloy with 8%
Sn appears to remain in the β-form down to the temperature of
liquid air. The lead constituent of the eutectic, however, appears to
remain in the metastable β-form. The density of the alloys confirms
the view that the lead constituent of the eutectic differs from the
stable α-solid solution.

A microscopic study of the eutectic alloy shows that it is composed
of grains, within each of which the crystallites have a definite
orientation. Each grain is to be regarded as a spherulitic crystal of
the β-solution, the tin forming a matrix or filling.

The paper is illustrated with photo-micrographs. C. H. D.
Electrolytic Corrosion of Brasses in Synthetic Sea-Water. 

Azariah T. Lincoln and G. C. Bartells, jun. (J. Physical Chem., 1908, 12, 550—556. Compare Lincoln, Klein, and Howe, Abstr., 1907, ii, 953).—The corrosion of fully annealed copper-zinc alloys was measured, using an artificial sea-water prepared by dissolving salts. The corrosion curves are similar to those obtained in solutions of sodium chloride. With the appearance of the γ-phase, copper ceases to appear in the corrosion product.

Recalculation of the Vapour Pressure of Mercury. T. H. Laby (Phil. Mag., 1908, [vi], 16, 789—796).—The recorded observations of the vapour pressure of mercury have been compared, and the more concordant values have been combined with the object of obtaining a table of most probable values. Two Kirchhoff formulæ are given which satisfactorily express the recorded observations. The vapour-pressure values (in terms of mm. of mercury at 0°) are recorded for every 5° between 15° and 365°, and also for 370°, 380°, 390°, 400°, and 450°. It is also shown that the experimental data of Cailletet, Colardeau, and Rivière for temperatures up to 700° can be satisfactorily expressed by means of a Kirchhoff formula.

Constitution of Certain Mercuric Compounds with Complex Cations. II. Vincenzo Borelli (Gazzetta, 1908, 38, ii, 421—474. Compare this vol., i, 515).—According to Abegg and Bodländer’s principle of electro-affinity (Abstr., 1899, ii, 542), the tendency of the mercuric halogen salts to form complex cations is weaker the stronger the anion combining with the mercuric ion to form the cation, since increase of the electro-affinity of the halogen radicle should be accompanied by an increase in the tendency of the radicle to dissociate according to the scheme: \( \text{HgX}^- \rightarrow \text{Hg}^{+} + \text{X}^- \). This is actually found to be the case, the tendency to form these complex ions being greatest with mercuric iodide and cyanide, less marked with the bromide, and so slight with the chloride that the corresponding double salt cannot be isolated. The author has studied the complex salts formed by mercuric iodide, bromide, chloride, and thiocyanate with mercuric perchlorate, the results obtained being parallel with those observed in the case of the similar complex salts yielded by mercuric cyanide. The behaviour of insoluble mercuric compounds of the type \( \text{HgX}'' \) toward mercuric salts with strong anions is quite analogous to that of the insoluble salts of the type \( \text{HgX}'' \).

Iodomercury perchlorate, \( \text{HgI} \cdot \text{ClO}_4 \), forms bundles or mammillary masses of white, opaque prisms, which deliquesce and turn yellow in the air, and are decomposed by water with liberation of mercuric iodide. Cryoscopic measurements in water give values for the molecular weight lower than that calculated for complete dissociation of the compound into its components and allowing for the partial hydrolysis of the mercuric perchlorate according to the equation: \( \text{Hg(ClO}_4)_2 + \text{H}_2\text{O} = \text{Hg(OH)} \cdot \text{ClO}_4 + \text{HClO}_4 \) (compare Heimbucher, Diss., Würzburg, 1904; Abstr., 1904, ii, 465). The depression of the
freezing point of water by mercuric perchlorate is diminished by mercuric iodide, the diminution increasing with the proportion of iodide present in the solution; the complex molecular concentration hence undergoes a corresponding diminution. Similar behaviour is observed when mercuric cyanide is dissolved in an excess of a concentrated solution of mercuric perchlorate. The conductivity of mercuric perchlorate solution is also diminished by the presence in the solution of mercuric iodide, owing to diminution of the ionic concentration and to the lower mobility of the new ions formed. The addition of mercuric iodide or cyanide produces an increase in the molecular concentration of mercuric perchlorate solution when this is not excessively concentrated, and a diminution when an excess of the perchlorate is present. These results are regarded as due to various reactions between the mercuric iodide and the ions, Hg" and ClO₄', originally present in the solution. The analogy between these results and those obtained with mercuric cyanide indicates that the mercuric iodide unites with the Hg" ions to give complex cations; this view is supported by transport measurements of solutions of mercuric iodide containing excess of the perchlorate.

*Bromomercuroy perchlorate*, HgBr⁺·ClO₄, forms bundles or mammillary masses of short, white prisms. When mercuric bromide is dissolved in a solution of mercuric perchlorate, it causes depression of the freezing point and regular elevations of the boiling point, and, consequently, an increase in the concentration. Into these solutions, mercuric bromide enters under the form of the ions HgBr⁺, and also, to a slight extent, of the ions Hg₂Br₂⁺⁺. The existence of these complex ions is shown by measurements of the variation of the concentration of mercuric bromide at the electrodes during electrolysis.

Chloromercuroy perchlorate could not be isolated. The presence of 1 mol. of mercuric chloride per mol. of the perchlorate in solution produces an increase of 0.028% in the original conductivity, but the addition of a further 1/5 mols. of the chloride causes no further increase. The conductivity curve shows that mercuric chloride exhibits a tendency to form the ions HgCl⁺ about 500 times less than the tendency of the cyanide to form the ions HgCN⁻.

The author has not succeeded in isolating chloromercuroy nitrate, HgCl⁺·NO₃ (compare Morse, Abstr., 1903, ii, 12), but conductivity measurements demonstrate the undoubted presence of the ions HgCl⁺ and NO₃⁻ in solutions containing mercuric chloride and nitrate.

*Thiocyanomercuroy perchlorate*, Hg(CNS)⁺·ClO₄⁻, was obtained as a white, crystalline crust. The addition of mercuric thiocyanate to a solution of mercuric perchlorate produces a diminution in the molecular concentration.

The author has been unable to prepare the compound,

\[ 2\text{Hg(ClO}_4\text{)}_2\cdot\text{HgO}\cdot12\text{H}_2\text{O} \]

described by Chikashigé (Trans., 1905, 87, 822), the products obtained being basic compounds containing approximately \(2\text{Hg(ClO}_4\text{)}_2\) per \(3\text{HgO}\). When mercuric oxide is dissolved in a solution of mercuric perchlorate, it produces diminution of the molecular concentration; the diminution produced increases with the concentration.
of the perchlorate solution, as, therefore, does the complexity of the compounds formed.

Precipitation of Gelatinous Mixtures of Alumina and Silica, and their Relation to Allophane, Halloysite, and Montmorillonite. H. Stremme (Centr. Min., 1908, 622—632, 661—669).—The gelatinous precipitates obtained from solutions of sodium silicate and aluminium acetate are of very variable composition, depending on the strength of the solutions and on their acidity. In an acid solution there is at first only a turbidity, and the gelatinous precipitate afterwards deposited is richer in silica than that from a neutral solution.

Carbonic acid and acetic acid dissolve the alumina more readily than the silica from the precipitates. The conclusion is drawn that these precipitates do not represent any definite hydrated aluminium silicate, but that they are simply mixtures of gelatinous aluminium hydroxide and hydrated silica. The same relations also exist in the various amorphous minerals of the clay group. The published analyses of these are tabulated, and they show wide variations in composition: for minerals of the allophane group, the ratio \( \text{Al}_2\text{O}_3 : \text{SiO}_2 \) varies from \( 1:0.31 \) to \( 1:1.91 \); for the halloysite group, \( 1:1.68 \) to \( 1:3.89 \); and for the montmorillonite group, \( 1:2.51 \) to \( 1:5.32 \). The conclusion is therefore drawn that these are not definite mineral species, but mixtures in variable proportions of colloidal aluminium hydroxide and hydrated silica.

L. J. S.

Ferromagnetic Nitrogen Compounds of Manganese. Edgar Wedekind and Theo. Veit (Ber., 1908, 41, 3769—3773. Compare Abstr., 1907, ii, 353; Shukoff, this vol., ii, 484).—With the object of ascertaining whether elements which are gases at the ordinary temperature form ferromagnetic derivatives with manganese, the nitrides of manganese have been investigated. Trimanganese nitride, \( \text{Mn}_3\text{N}_2 \) (compare Prelinger, Abstr., 1894, ii, 16), has only feeble magnetic properties, whilst pentamanganese nitride, \( \text{Mn}_5\text{N}_3 \), is slightly more magnetic. The nitride, \( \text{Mn}_7\text{N}_3 \), obtained by the action of ammonia on manganese heated with an oxy-hydrogen blowpipe, has stronger magnetic properties than either of the above nitrides, and is almost as magnetic as manganese boride; it is readily attacked by acids and alkalies.

Chromium nitride, \( \text{CrN} \), has only feeble magnetic properties.

W. H. G.

The System Iron—Phosphorus. E. Gercke (Metallurgie, 1908, 5, 604—609).—Alloys rich in phosphorus were prepared by adding red phosphorus to molten iron in a magnesite crucible. The product containing 17·3% P was re-melted with different proportions of iron. The eutectic temperature is 980°; mixtures low in phosphorus show considerable undercooling. Iron retains up to 1·70% of phosphorus in solid solution, beyond this the eutectic, containing 10·2% P, is present as a constituent. The solid solution undergoes a change of structure, which has not been fully investigated, at 600°.

C. H. D.
The Ternary System Iron–Phosphorus–Carbon. Paul Goerens and W. Dobbelstein (Metallurgie, 1908, 5, 561—566. Compare Wüst, this vol., ii, 287).—The ternary eutectic point of the system is found to lie at 1.96% C, 6.39% P, and 91.5% Fe, and at 953°. The position of the three binary eutectic curves in the system iron–iron carbide–iron phosphide has also been determined. Both thermal and microscopic methods have been employed.

The microscopic sections are best prepared by etching and heat-tinting, subsequently re-polishing lightly. The oxide film is much more readily removed from cementite than from the phosphide, thus allowing the two to be distinguished.

C. H. D.

The Iron–Carbon Equilibrium. George B. Upton (J. Physical Chem., 1908, 12, 507—549).—The results of other observers are examined and recalculated, the silicon and other elements present in the samples examined being calculated as "equivalent carbon." The author concludes that cementite must find a place in the diagram of stable equilibrium, and he assumes the formation of three carbides in all, Fe₃C, Fe₅C, and Fe₇C, of which the first is stable only above 800° and the second above 600°. The brittleness of steel at 500—550° is considered to be due to the change from Fe₃C to Fe₇C. An equilibrium diagram has been constructed on these assumptions.

C. H. D.

Hydrolysis of Ferric Chloride; Influence of Neutral Salts. G. Malfitano and Leopold Michel (Compt. rend., 1908, 147, 803—806. Compare Abstr., 1907, ii, 692; this vol., ii, 111, 288).—The phenomena of the colloidal state are more pronounced and appear more rapidly in solutions of ferric chloride to which potassium chloride has been added than in solutions of ferric chloride alone. The authors have measured the increase in electrical conductivity of solutions of ferric chloride, alone and with varying amounts of potassium chloride, produced by raising the temperature from 18° to 100° for fifteen minutes, and after allowing the solutions to remain for sixteen and twenty-four hours respectively. The results lead to the conclusion that the rate of hydrolysis of the ferric chloride depends on the proportion of potassium chloride present, and that the size of the micro-cells of ferric hydroxide is increased by the addition of this salt. The number of ferric ions being diminished, there are fewer centres of attraction for the ferric hydroxide molecules, and consequently the individual cells are more voluminous.

The chlorides of sodium, ammonium, barium, and magnesium, and also potassium nitrate, behave in a similar manner. Mercuric chloride, on the other hand, being a non-electrolyte, has no appreciable influence on the course of the hydrolysis. Salts containing multivalent negative ions, such as potassium sulphate, behave like the multivalent acids previously studied in hindering hydrolysis.

W. O. W.

Molybdates of Nickel and Cobalt. M. Emmanuel Pozzi-Escot (Bull. Soc. chim., 1908, [iv], 3, 1012).—The author has been informed by Marckwald that the attribution to the latter by Grossmann and
Schück (this vol., ii, 230) of certain work on nickel and cobalt molybdates is inaccurate.

T. A. H.

Antimony Trichloride as Ionising Solvent. Z. Klemensiewicz (Bull. Acad. Sci. Cracow, 1908, 485—494).—The measurements were made by the electrical conductivity method with platinised electrodes in the usual way. The carefully-purified solvent has $D^7 2.681$ and $D^9 2.647$; the smallest conductivity observed amounted to $8.5 \times 10^{-7}$ reciprocal ohms.

As solutes, the chlorides of potassium, rubidium, ammonium, and thallium were used, and measurements were made up to a dilution of 1024 litres and at different temperatures. The conductivities in dilute solutions are greater, in concentrated solutions (above $N/10$) less, than for the corresponding aqueous solutions. It is probable that the degree of ionisation is less for solutions in antimony chloride than in water, but that the ionic velocity is greater in the former case. The conductivity of the solutions increases regularly with the temperature from $70^\circ$ to $150—200^\circ$.

The viscosity of antimony trichloride has been measured from $80^\circ$ to $200^\circ$. The curve obtained by plotting the fluidity (reciprocal of the viscosity) against the temperature appears to show a change of direction at $120^\circ$, but a high degree of accuracy is not claimed for the results.

G. S.

Melting-point Curves for the Systems Bismuth + Chlorine and Bismuth + Bromine. B. G. Eggink (Zeitsch. physikul. Chem., 1908, 64, 449—505).—After reviewing the various compounds of bismuth with chlorine and bromine which have been described, the author proceeds to a theoretical discussion of the possible liquid-solid equilibria in a system of two components in which two liquid phases may occur. In this discussion, the author uses the graphical method introduced by van Ryn van Alkemade (Abstr., 1898, ii, 363).

The experimental study of the systems bismuth + chlorine and bismuth + bromine has shown that compounds of the formulae $\text{BiCl}_3$ and $\text{BiBr}_3$ exist, which, on melting at $320^\circ$ and $287^\circ$ respectively, both form two liquid phases. Further, an endothermic compound $\text{BiCl}_4$ exists, which is only slightly dissociated in the fused condition. So far as the evidence of the freezing-point curve goes, there are no compounds of the formulae $\text{BiCl}_2$, $\text{BiBr}_2$, and $\text{BiCl}_6$; the author's results are therefore not in harmony with those of Herz and Guthmann (this vol., ii, 199).

J. C. P.

Columbium. Clarence W. Balke and Edgar F. Smith (J. Amer. Chem. Soc., 1908, 30, 1637—1668).—A continuation of the investigation of the compounds of columbium and tantalum (Abstr., 1905, ii, 828, 829). The conclusion is confirmed that the coloration produced on the addition of hydrogen peroxide to a solution of columbium in hydrofluoric acid is not due to the presence of titanium, but is probably due to columbium itself. A large quantity of potassium columbium fluoride, $K_2 \text{CbF}_7$, was prepared and carefully purified, and was after-
wards converted into the oxide, which had D 4.8. This oxide still gave the reaction with hydrogen peroxide, and, in order to study further the question as to whether the reaction might not be due to the presence of some other element, the oxide was converted into the chloride, and the latter fractionally distilled. The whole of the product distilled at about 241°, and no differences could be detected between the fractions obtained. On a spectroscopic examination of the oxide prepared from the chloride, neither tantalum nor titanium lines were observed. Vapour density determinations of the chloride by Dumas' method gave a mean value of 9.45, as compared with the calculated value 9.35 [Cb = 93.5]. Specimens of the oxide prepared from the chloride had D varying from 4.48 to 5.02. The chloride had D 2.73—2.77. A careful determination of the atomic weight of columbium based on the ratio between the chloride and oxide gave as mean of eight determinations the value 93.50 [O = 16; Cl = 34.45].

A résumé is given of the various columbates described in the literature. Sodium columbate, Na₂O,Cb₂O₅,7H₂O, crystallises in triclinic prisms \( a:b:c = 0.9559 : 1 : 0.8394; \alpha = 71°20'; \beta = 105°30'; \gamma = 54°7' \). Magnesium columbate, Mg₂O,Cb₂O₅,7H₂O, the silver salt, Ag₂O,Cb₂O₅,2H₂O, the copper salt, Cu₂O,Cb₂O₅,3½H₂O, the aluminium salt, Al₂O₃,Cb₂O₅,12H₂O, and the cadmium salt, CdO,Cb₂O₅,3½H₂O, are described. The potassium salt, 4K₂O,3Cb₂O₅,16H₂O, forms monoclinic crystals \( a:b:c = 0.7120 : 1 : 0.5547; \beta = 84°19' \). The rubidium salt, 4Rb₂O,3Cb₂O₅,14H₂O, is isomorphous with the salts 4Rb₂O,3Ta₂O₅,14H₂O, 4Cs₂O,3Cb₂O₅,14H₂O, and 4Cs₂O,3Ta₂O₅,14H₂O, and crystallises in monoclinic prisms \( a:b:c = 0.8815 : 1 : 1.4091; \beta = 84°7' \). The following columbates are also described: 7K₂O,6Cb₂O₅,27H₂O, 7Li₂O,6Cb₂O₅,26H₂O, 7Cs₂O,6Cb₂O₅,30H₂O, and 3Rb₂O,4Cb₂O₅,9½H₂O.

The following percolumbates have been obtained: Na₃CbO₈, K₃CbO₈, Rb₃CbO₈, Cs₃CbO₈, MgNaCbO₈,8H₂O, MgKCbO₈,7H₂O, MgRbCbO₈,7½H₂O, MgCsCbO₈,8H₂O, CaNaCbO₈,4H₂O, and CaKCbO₈,4H₂O.

The sodium columbium fluorides, 3NaF,CbOF₃ and 3NaF,CbOF₃,F₃H₂O, have been prepared, but the salts, 2NaF,CbOF₃,2H₂O and NaF,CbOF₃,F₃H₂O, described by Marignac could not be obtained. The existence of the potassium salts, 2KF,CbOF₃,H₂O, 3KF,CbOF₃, 3KF,HF,CbOF₃, 5KF,3CbOF₃,H₂O, 4KF,3CbOF₃,2H₂O, and 2KF,CbF₃, described by Marignac, was confirmed. The salt 3KF,HF,CbOF₃ forms monoclinic needles \( a:b:c = 0.6304 : 1 : 0.4888; \beta = 86°41' \). The double fluoride, 2RbF,CbF₃, described by Pennington (Abstr., 1896, ii, 305) could not be obtained, but the following salts were prepared: 2RbF,CbOF₃, RbF,CbF₃, and 2RbF,CbOF₃,H₂O. The rubidium tantalum salt, 2RbF,TaOF₃,F₃H₂O, forms thin, white leaflets. The caesium salts, 2CsF,CbOF₃ and CsF,CbF₃, are described. The thallium salt, 2TlF,CbOF₃, forms orthorhombic crystals \( a:b:c = 0.4261 : 1 : 1.0129 \).
A study has been made of the double tantalates. The salt
\[ 4\text{Rb}_3\text{Ta}_5\text{O}_{14}\text{H}_2\text{O} \]
forms monoclinic crystals \[a:b:c=0.8822:1:0.0510; \beta=84^\circ2'\].
The salts \[ 4\text{Cs}_2\text{O}_5\text{Ta}_2\text{O}_{14}\text{H}_2\text{O} \] and \[ 7\text{Cs}_2\text{O}_6\text{Ta}_2\text{O}_{38}\text{H}_2\text{O} \] are also described.

The following per-tantalates have been prepared: \[ \text{Rb}_3\text{Ta}_5\text{O}_{14}\text{H}_2\text{O}, \text{Cs}_2\text{Ta}_5\text{O}_{14}\text{H}_2\text{O}, \] \[ \text{MgNaTa}_5\text{O}_{8}\text{H}_2\text{O}, \text{MgKTa}_5\text{O}_{7}\text{H}_2\text{O}, \] \[ \text{MgRbTa}_5\text{O}_{9}\text{H}_2\text{O}, \text{and CsNaTa}_5\text{O}_{4}\text{H}_2\text{O}. \]

**E. G.**

**Spectrum and the Bromides of Columbium.** William M. Barr (J. Amer. Chem. Soc., 1908, 30, 1668—1672).—It has been shown by Hall and Smith (Abstr., 1905, ii, 829) that the hydrogen peroxide test for titanium in a solution of columbium in hydrofluoric acid is not trustworthy. For this reason, spectroscopic examination has been resorted to. Hildebrand (following abstract) has submitted carefully purified columbium oxide prepared by Balke and Smith (preceding abstract) to a spectroscopic examination, and has found that, whilst nearly all the titanium lines were absent from the spectrum, certain lines were present which are common to both metals. A study has therefore been made of the spectra of specimens of columbium oxide prepared from minerals of different character and from different localities, and purified by Balke and Smith’s methods. The results indicate that these methods of purification are efficient, that the spectra of columbium from all sources are identical, and that the lines common to both the columbium and titanium spectra are not due to the presence of titanium in the columbium, and probably not to any other element, but are merely coincident lines.

The “Niobunterbroucid” described by Rose (Ann. Phys. Chem., 1858, 104, 441) has been studied, and found to be columbium oxy-bromide, \( \text{CbOBr}_3 \). The dark red compound formed simultaneously is the pentabromide, \( \text{CbBr}_5 \), as stated by Rose. Both these salts are described.

A **columbium iodide** has been prepared from the bromide, and is being investigated.

**E. G.**

**Arc Spectrum of Columbium.** Joel H. Hildebrand (J. Amer. Chem. Soc., 1908, 30, 1672—1684. Compare Balke and Smith, and Barr, preceding abstracts).—The arc spectrum of columbium has been measured between \( \lambda 2600 \) and \( \lambda 6000 \), using specimens of the oxide obtained from euxenite, tantalite, columbite, and aeschynite. The results are tabulated.

It has been found that Balke and Smith’s method for preparing columbium oxide, free from titanium, is satisfactory, and that the existence of any element common to columbium and titanium is very improbable. The identity of the spectra of columbium from different sources affords strong evidence of its elementary character.

**E. G.**

Metallographic and Metallurgical Notes. [Thermal Diagrams. Microscopy of Alloys.] K. Friedrich (Metallurgie, 1908, 5, 593—604).—I. It was found impossible to obtain thermal
diagrams of the systems platinum-sulphur, gold-selenium, gold-sulphur, gold-arsenic, or zinc-sulphur on account of the volatility of one component. The existence of the sulphide, Zn_2S, is improbable.

II. The use of ultra-violet light in the microscopic study of alloys is not found to have any advantages.

Atomic Weight of Palladium. George I. Kemmerer (J. Amer. Chem. Soc., 1908, 30, 1701—1705).—The results of previous work on the atomic weight of palladium show considerable variation, and, for this reason, the present investigation was undertaken. The experiments were carried out with (A) palladiodiammonium chloride purified by Keller and Smith's method (Abstr., 1893, ii, 73); (B) the same salt purified by means of ammonium cyanide instead of the mercuric cyanide used by Keller and Smith, and ammonium salts instead of sodium or potassium salts, and (C) palladiodiammonium cyanide, Pd(NH_3)_2CN. In each case a porcelain boat containing the salt was enclosed in a tube heated by an electric heater, and was reduced to the metal by means of carefully-purified electrolytic hydrogen. The following results were obtained: salt A, mean of five experiments, 106.399; salt B, mean of four experiments, 106.442; salt C, mean of six experiments, 106.458. The mean value of all the determinations gave an atomic weight, 106.434 [Cl = 35.473; H = 1.008; N = 14.01].

Mineralogical Chemistry.

Natural Zirconium Oxide Free from Iron. Edgar Wedekind (Zeitsch. angew. Chem., 1908, 21, 2270—2271).—Of the three forms in which Brazilian zirconium ore occurs, that containing the greatest amount of zirconium is the black, glassy, lump variety; analysis gave:

\[
\begin{align*}
\text{ZrO}_2 & : 94.12 \\
\text{TiO}_2 & : 0.98 \\
\text{Fe}_2\text{O}_3 & : 3.22 \\
\text{SiO}_2 & : 0.43 \\
\text{ZrSiO}_4 & : 1.98 \\
\text{Total} & : 100.73
\end{align*}
\]

When examined under the microscope, this mineral was found to be composed of black particles embedded in a brownish-yellow, powdery substance. When separated mechanically, the black portion was found to be quite free from iron; analysis gave:

\[
\begin{align*}
\text{ZrO}_2 & : 97.97 \\
\text{SiO}_2 & : 1.72 \\
\text{TiO}_2 & : 1.20 \\
\text{Insol} & : 0.10 \\
\text{Total} & : 100.99
\end{align*}
\]

From this it is evident that the colour previously ascribed to the presence of iron must be caused by the titanium, as, indeed, must be the colour of many other stones and minerals. Crystalline, natural zirconium oxide is feebly radioactive; it has D 5.41, a value somewhat higher than that, D 5.1, of the artificial, crystalline substance.

J. V. E.
Krohnkite, Natrochalcite (a New Mineral), and Other Sulphates from Chile. Charles Palache and Charles H. Warren (Amer. J. Sci., 1908, [iv], 26, 342—348*).—The specimens described are from copper veins in the mining district of Chuquicamata, in the province of Antofagasta, and include krohnkite, natrochalcite, blödite, brochantite, atacamite, chalcantite, copiapite, botryogen, sideronatrite, halite, and gypsum.

**Krohnkite.**—The large, well-developed crystals are monoclinic, with \( a : b : c = 0.5229 : 1 : 0.4357 ; \beta = 56°17' \); they are twinned on (001), and have a perfect cleavage parallel to (010); hardness 2½. Three types of specimens are distinguished: (i) clusters of octahedroid crystals of a dull greenish-blue colour; (ii) single prismatic crystals and fibrous or acicular aggregates of a pale blue colour; (iii) solid crusts of large, prismatic crystals of a deep vitriol-blue colour. Analysis I gives the usual formula: \( \text{CuSO}_4 \cdot \text{Na}_2 \text{SO}_4 \cdot 2\text{H}_2\text{O} \). The water is mainly given off below 150°, but small amounts continue to come off up to 350°. The mineral is fusible without decomposition to a bright green enamel.

**Natrochalcite.**—This new species occurs as bright emerald-green, monoclinic crystals with an acute pyramidal habit \( [a : b : c = 1.423 : 1 : 1.214; \beta = 61°17\frac{1}{2}'] \). Cleavage (001) perfect; hardness 4½. Complete optical determinations are given for this, as also for krohnkite. Analysis II agrees with \( \text{Na}_2\text{SO}_4 \cdot \text{Cu}_4(\text{OH})_2(\text{SO}_4)_2 \cdot 2\text{H}_2\text{O} \). The water is given off gradually above 150°, and between 350° and a low red-heat, sulphuric anhydride is expelled. The mineral readily fuses to a black bead.

**Blödite.**—Analysis III, of massive, granular material, agrees with the usual formula: \( \text{MgSO}_4 \cdot \text{Na}_2\text{SO}_4 \cdot 4\text{H}_2\text{O} \).

**Analyses of Gabbronitic Rocks from Neurode, Silesia.** Felix Tanhaüser (Sitzungsber. k. Akad. Wiss. Berlin, 1908, 1069—1075).—Nine analyses are given of gabbro, anorthosite, pyroxenite, olivine-gabbro, troctolite, serpentine, diabase, gabbro-aplite, and spessartite. L. J. S.

---

**Physiological Chemistry:**

**Heats of Solution of Gases in Blood.** Mario Camis (Mem. Real. Accad. Sci. Torino, 1908, [ii], 58, 141—169).—The author has measured calorimetrically the heat changes occurring when oxygen and carbon dioxide pass into, or out of, solution in blood. The absorption of 1 gram-mol. of carbon dioxide by the blood is accompanied by the evolution of 5.40 Cal., the corresponding value for oxygen being...

10.22 Cal. Taking mean numbers for the daily respiratory exchange, it is calculated that, for a man weighing 70 kilos., this exchange leads to the production of about 127 Cal. per day. The blood pigment and the oxygen absorbed probably react endothermically. The paper concludes with a bibliography.

Estimation of the Respiratory Capacity of Small Quantities of Blood. Heinrich Dreser (Arch. exp. Path. Pharm., Suppl., 1908, 138—149).—Certain modifications of Haldane's carbon monoxide method, and of Barcroft's gas analysis methods, are proposed. In investigating the effect of certain antipyretics on the respiratory capacity, it was found that many of these produce methaemoglobin formation, and the oxygen so combined is not displaced by carbon monoxide. A comparison of \( m \)-tolylhydrazine, \( \beta \)-acetylphenylhydrazine (pyrodine), and the semicarbazide of \( m \)-tolylhydrazine shows that the semicarbazide substitution is much less harmful than the acetyl substitution, as in acetonilide and phenacetin.

W. D. H.

Glycine in Normal Blood. Adolf Bingel (Zeitsch. physiol. Chem., 1908, 57, 382—388).—By the use of the Fischer-Bergell naphthalenesulphonyl chloride method, it is possible to demonstrate the existence of glycine in normal ox-blood. From 10 litres, 0.2 gram of the glycine compound was obtained. A higher amino-acid, or a peptide-like substance, is also present.

W. D. H.

Reaction of the Blood after Intravenous Injection of Acid and Alkali. N. van Westenryk (Arch. exp. Path. Pharm., Suppl., 1908, 517—527).—That, the titration method shows the blood to be alkaline is due to the fact that the acid used may displace a weaker acid in neutral salts. Many indicators are not indifferent chemical substances, but may be themselves acid or basic. By the use of neutral-red and other indicators, the reaction of the blood is shown to be neutral, and remains neutral under various pathological conditions. It alters in experimental acid or alkali poisoning. Alkali poisoning produces stimulation, increasing the action of the heart and kidneys; acid produces the opposite effects. In acid poisoning, the organism remains neutral, as the acid is fixed and neutralised in the muscular tissues. Previous observations that the alkalinity of the blood decreases on destruction of the red corpuscles, are confirmed by the new methods.

W. D. H.

Spectrophotographic Investigations on the Action of Hydrocyanic Acid on Blood. Louis Lewin (Arch. exp. Path. Pharm., Suppl., 1908, 337—348).—Details are given of the spectroscopic appearances of blood and hemoglobin treated with hydrocyanic acid. Cyanomethaemoglobin and cyanohaematin do not appear to exist; the spectroscopic appearances of their so-called compounds are identical with those of cyanohaemoglobin. Blood so treated catalyses hydrogen peroxide quite typically. The cause of the toxic action of hydrocyanic acid is discussed, and the conclusion is drawn that it is not a blood poison in the biological sense.

W. D. H.
Path. Pharm., Suppl., 1908, 126—137).—The relative activity of
oxidising salts on the blood and tissues runs fairly parallel to their
oxidising power on simpler chemical compounds. But in many cases
other factors step in. The blood corpuscles and pigment react more
readily to weak oxidising agents than do muscle or epithelium. In
certain cases, also, substances which oxidise blood corpuscles and
pigment readily are feeble oxidising agents for simpler chemical
substances; the reverse is also seen.

W. D. H.

Hæmolytic Action of Mercury Salts. J. Dunin-Borkowski
(Bull. Acad. Sci. Cracow, 1908, 494—505).—The hæmolytic action of
mercury salts on the serum-free blood corpuscles (erythrocytes) of
different animals has been investigated. With mercuric chloride, the
resistance to hæmolysis increases in the order: guinea-pig, sheep,
cow, pig, calf, dog. A higher concentration of mercuric chloride
than that required to produce complete hæmolysis, agglutinates the
erythrocytes.

Mercuric iodide has considerable hæmolytic activity, and mercuric
cyanide, although not ionised, is almost as active as the chloride.
Potassium cyanide is less active than mercuric cyanide. It follows
that hæmolysis does not depend on the concentration of Hg⁺ ions
alone, although the ionic concentration probably has some effect, as
sodium chloride lessens the activity of mercuric chloride.

The rate of hæmolysis with different concentrations of mercuric
chloride has also been measured. With small concentrations, the
constants calculated for a unimolecular reaction diminish, and with
fairly high concentrations they increase considerably during the
reaction, being approximately constant for intermediate concen-
trations.

The temperature-coefficient for 10° between 18° and 25° is 4.37 for
erthrocytes from the guinea-pig, and 2.6 between 18° and 32° for
those from the dog. The coefficient is much greater at higher
temperatures, owing to the fact that hæmolysis is produced to some
extent by heat alone, and, further, the erythrocytes which have
been heated alone for some time are much more readily acted on
by mercuric chloride than those which have not been heated.

G. S.

Peptolytic Ferments in the Stomach Contents. Emil
Anderhalden and Florentin Medighceanu (Zeitsch. physiol. Chem.,
1908, 57, 317—324).—The observations were made on a dog with
a gastric fistula, and confirm those made by Boldyreff, that, after a
meal rich in fat, the contents of the duodenum regurgitate into the
stomach. Under these conditions, the stomach contents contain a
peptolytic ferment, and when neutralised, resolve glycyl-L-tyrosine into
its constituent amino-acids. Under ordinary conditions, however,
the ferment is rendered rapidly inactive by the acid of the gastric
juice.

W. D. H.
Influence of the Products of Reaction on the Hydrolysis of Fats by Pancreatic Juice. Mlle. L. Kalaboukoff and Émile Terrone (Compt. rend., 1908, 147, 712—715).—Both fatty acids and their sodium salts diminish the rate of hydrolysis; glycerol, on the other hand, has a considerable accelerating action. This acceleration does not take place when a soluble ester, such as mono-butyrin, or natural emulsions, such as egg-yolk or cream, or solid fats, such as lard, are submitted to the action of the juice. The action of the glycerol is to be ascribed to the fact that a better distribution of the lipase between the aqueous and oily phases takes place in its presence; other syrupy substances can produce a similar acceleration.

S. B. S.

Digestion in Animals. XXVII. Relationship of Concentration to Absorption in the Intestine. E. S. London and W. W. Polowitzowa (Zeitsch. physiol. Chem., 1908, 57, 529—546. Compare this vol.; ii, 960).—Details are given of the relative amount of absorption in the intestine of the water and sugar contained in solutions of dextrose of different concentrations.

W. D. H.

Absorption of Fat from Intestinal Loops in Dogs. O. H. Plant (Amer. J. Physiol., 1908, 23, 65—80).—Bile salts increase the absorption of fats from a mixture which contains free fatty acid or soap; they only slightly increase the absorption of neutral oil. Solutions of soap, or biliary solutions of fatty acids, are absorbed more rapidly than emulsified fats. If both bile and pancreatic juice are excluded from the intestinal loop, neutral oil is nevertheless absorbed, and it becomes markedly acid in reaction. Taken as a whole, the experiments favour the view that fats are absorbed in solution rather than as an emulsion.

W. D. H.

Absorption of Iodised Proteins. Otto von Fürth and M. Friedmann (Arch. exp. Path. Pharm., Suppl., 1908, 214—223).—An iodised protein (iodalbacid) is before absorption in the cat's intestine broken down in large measure so completely that the iodine in the intestinal wall and blood is not in combination as proteose or peptone, but only as alkali iodides.

W. D. H.

Action of Intestinal Astringents on Metabolism. Karl Spiro (Arch. exp. Path. Pharm., Suppl., 1908, 504—512).—Opium, bismuth subnitrate, and tannigen produce but little change in nitrogenous metabolism in dogs. With opium the C:N ratio in the urine goes up, this is due to a fall in the nitrogen; the nitrogen in the faeces is but little altered. Tannigen, on the other hand, causes a loss of urinary, and an increase of fecal nitrogen, the total excretion of nitrogen being about the normal; a sinking of the C:N ratio in the urine is mainly due to a relative decrease in the excretion of carbon.

W. D. H.

Creatinine Metabolism. G. Lefmann (Zeitsch. physiol. Chem., 1908, 57, 476—514).—The excretion of creatinine and creatine is
pretty constant in well nourished animals. If either substance is added to the food, it is excreted unchanged. If creatine is given by the mouth or parenterally, it is never changed into creatinine; in inanition it is almost completely excreted as such. Disease of the liver or increased protein catabolism produce first an increase, then a decrease, in creatinine excretion, and when it is lessened, the amount of creatine excreted increases. The liver is the probable seat of creatinine formation. If nephritis is induced by chromates, nearly all the creatinine is changed into creatine, probably by the alteration in the reaction of the urine.

W. D. H.

The Changes in Gaseous Metabolism after Exclusion of the Hepatic Circulation. Vittorio Scaffidi (Biochem. Zeitsch., 1908, 14, 156—179).—Experiments were carried out on ducks, the liver circulation being excluded by ligaturing the portal vein. As birds were employed for the experiments, it was not necessary to make an Eck fistula. The absorption of oxygen and excretion of carbon dioxide were determined both before and after the operation. It was found that the operation caused an increase in the oxygen absorption and in the carbon dioxide excretion, and also an increased respiratory quotient. These results are probably due to the inhibition of glycogen storage, owing to the liver being thrown out of circulation. There is consequently an increased destruction of the carbohydrates, which are thrown into the circulation. The increased respiratory quotient, which is particularly noticeable at some interval after the operation, is probably due to the conversion of the carbohydrate into fat.

S. B. S.

Starvation Metabolism. Mieczyslaw Halpern (Biochem. Zeitsch., 1908, 14, 134—142).—The urine of a patient unable to ingest either food or water, owing to cancer in the esophagus, was analysed. The total daily excretion of nitrogen was 2·058 grams, or, excluding the protein nitrogen excreted, 2·0097 grams. This is less than that found in most other starvation cases, owing probably to the fact that the organism had gradually accommodated itself to a low diet. Other anomalies were also observed, for the ammonia nitrogen was only 3·47% of the total. The excretion of the acetone substances was also small. The purine substances were also small in amount, the daily excretion of purine nitrogen being only 0·05897 gram. The sodium chloride excretion was 0·05265 gram daily, whilst the ratio \( N : P_{2}O_{5} \) was 6·3 : 1, which is normal and higher than in other starvation cases. The author discusses the possible reasons for the anomalies.

S. B. S.

The Nutritive Value of Protein Cleavage Products. VIII. Emil Abderhalden (Zeitsch. physiol. Chem., 1908, 57, 348—362. Compare this vol., ii, 961).—Dogs react differently by feeding on protein cleavage products, some being attacked with vomiting. But in those which do not react in this way, equilibrium and health are well maintained. Complete details of the experiments are tabulated. The same result was obtained also with the products of acid hydrolysis.
Phosphorus in Certain Foods WOLFGANG HEUBNER and M. REEB (Arch. exp. Path. Pharm., Suppl., 1908, 265—272).—The phosphorus-containing substances in foods fall into five groups, namely, inorganic phosphates, phoshatides, nuclein, phosphoproteins, and esters of phosphoric acid. The position of inosic acid and phosphoramic acid in this classification is uncertain. A method is described for estimating these various compounds, and the results of the examination of various foods, meat, milk, bread, and other vegetable foods, are given in a table.

Absorption and Assimilation of Organic Compounds of Phosphorus. PIO MARFORI (Arch. exp. Path. Pharm., Suppl., 1908, 378—388).—Natural glycerophosphoric acid differs from the synthetic substance in that its salts, when injected subcutaneously, yield, at least in part, assimilable phosphorus. The phosphorus of lecithin, and, to some extent, that of nucleo-proteins, is also assimilated under these conditions. Nuclein and nucleic acid from yeast, when given by the mouth, did not increase phosphorus assimilation.

The Cleavage of 2:5-Diketopiperazines in the Organism of the Rabbit. II. EMIL ABDERHALDEN and LEONHARD WACKER (Zeitsch. physiol. Chem., 1908, 57, 325—328. Compare this vol., ii, 521).—In the further investigation of this question, it appeared desirable to employ an anhydride which is decomposed by alkali with difficulty. The one selected was dl-leucylglycine anhydride, and the experiments confirm those previously reported; this substance is in small measure resolved into its components by the organism of the rabbit.

The Degradation of Aromatic Substances in the Human Organism. LEON BLUM (Arch. exp. Path. Pharm., 1908, 59, 273—298).—When administered to normal individuals, neither phenylalanine nor tyrosine, normal hydrolysis products of proteins, increase appreciably the aromatic contents of the urine. On the other hand, when given to alcaptonurics, they increase the homogentisic acid excretion in the urine. It has been assumed, therefore, that homogentisic acid is a normal intermediate product of metabolism of aromatic hydrolysis products of proteins, and that alcaptonuric individuals do not possess the power of completely utilising these products, and that tyrosine in the normal individual is first converted into homogentisic acid. This change can take place in the following ways: (a) the degradation may commence in the side-chain,
in which case \( p \)-hydroxyphenylactic acid, or hydro-\( p \)-coumaric acid, \( \text{OH} \cdot \text{C}_6\text{H}_4\cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CO}_2\text{H} \), is first formed, and subsequently converted into homogentisic acid. It was found by Baumann and Schotten that \( p \)-hydroxy-coumaric acid, when administered to normal individuals, gave rise to \( p \)-hydroxybenzoic acid to the extent of 13\%, whereas \( p \)-hydroxyphenylactic acid was recovered to the extent of 78.6\% in the urine. The author found that neither of these acids, on administration to alcaptonurics, caused an increase in the homogentisic acid output.

(b) A change in the relative positions of the hydroxyl group and the side-chain may take place with the formation of \( m \)- or \( o \)-tyrosine, which, on secondary oxidation in the para-position and a degradation of the side-chain, could give rise to homogentisic acid. It was found that neither of these tyrosines, when administered to alcaptonurics, increased the homogentisic acid output, and when given to normal individuals they were excreted in the form of the corresponding hydroxyphenylactic acids to the extent of about 30\%.

(c) The side-chain may be degraded to acetic acid, with a concurrent change in the relative position to the hydroxyl group, forming \( m \)- or \( o \)-hydroxyphenylactic acid. Homogentisic acid would be formed from such products by subsequent oxidation in the para-position. This possibility was unlikely, as neither \( o \)-nor \( m \)-tyrosine gave rise to homogentisic acid, and it was also found that \( m \)-hydroxyphenylactic acid, when administered to normal individuals, was found unchanged in the urine to the extent of 80\%. Neither \( o \)-nor \( m \)-acid gave rise to increased homogentisic output in alcaptonurics.

(d) The processes of degradation, change of relative positions of the hydroxyl group to the side-chain containing the acid group, and of secondary oxidation, can take place concurrently. A similar change has been observed by Bamberger, who showed that tolylhydroxylamine is converted by hot dilute sulphuric acid into toluquinol. Other examples of similar action are also known, and quoted by the author. A change of this description must take place when tyrosine is converted into homogentisic acid. The results also indicate that homogentisic acid is a normal intermediate product of metabolism, as none of the products which were not fully destroyed in the normal individual gave rise to increased homogentisic output in alcaptonurics.

\( m \)-Tyrosine was prepared by the condensation of \( m \)-hydroxybenzaldehyde with hippuric acid. The lactimide of \( m \)-hydroxybenzoylaminocinnamic acid in the form of its acetyl derivative, \( \text{C}_16\text{H}_{28}\text{O}_2\text{N} \), m. p. 149\(^\circ\), was obtained. On hydrolysis with 10\% sodium hydroxide solution, \( m \)-hydroxybenzoylaminocinnamic acid, \( \text{C}_{10}\text{H}_{18}\text{O}_4\text{N} \), m. p. 205—206\(^\circ\), was formed, which, on reduction with sodium amalgam, yielded \( m \)-benzoyltyrosine, \( \text{C}_{11}\text{H}_{16}\text{O}_4\text{N} \), m. p. 180\(^\circ\). From this, \( m \)-tyrosine, \( \text{C}_9\text{H}_{11}\text{O}_5\text{N} \), m. p. 280—281\(^\circ\), was obtained by hydrolysis with 20\% hydrochloric acid.

\( o \)-Tyrosine was obtained by a similar synthetic method, although all the intermediate products were not obtained pure. \( o \)-Benzoyltyrosine melts at 176\(^\circ\), and \( o \)-tyrosine at 249—250\(^\circ\).

S. B. S.
Are there Reducing Ferments in the Animal Body? **Arthur Heffter** (Arch. exp. Path. Pharm., Suppl., 1908, 253—260).—The reduction processes which occur in animal organs or their extracts, or in vegetable tissues, have been attributed to enzyme action. Boiling does not abolish the action; this and other considerations lead the author to the conclusion that "reductases" do not exist.

W. D. H.

Spectroscopic Properties of Yolk of Egg. **Louis Lewin, A. Miethe, and E. Stenger** (Pflüger's Archiv, 1908, 124, 585—590).—Attempts are being made to establish relationships between the colouring matters of egg-yolk and blood on account of the close morphological relationship between the blood and yolk. The first step in this direction has been the careful spectroscopic examination of the colouring matter of the yolk. The plates used for photographing the spectra were dyed with isocol. Solutions in water, acetone, alcohol, ether, chloroform, and benzene were examined. The solutions were found to follow Kundt's rule, for example, the absorption bands of the chloroform and benzene solutions were 5—10μμ nearer the red end of the spectrum than the corresponding bands of the other solutions.

There are three characteristic bands at 480, 453, and 427, and feebler bands at 400 and 378. No other yellow colouring matter gives the same absorption bands, and it is thus possible to detect adulterants of yellow of egg by spectroscopic measurements.

J. J. S.

Chemico-physical Investigations on the Crystalline Lens. **Filippo Bottazzi and Noè Scalinci** (Atti R. Accad. Lincei, 1908, [v], 17, ii, 305—316. Compare this vol., ii, 966).—The crystalline lens contains an electro-negative protein, facoprotein, which is only soluble in water in the form of acid protein in absence of alkali, or of alkali protein, which is soluble also in absence of salts. The essential material of the lenticular fibre is, in normal conditions, a hydrogel of liquid or gummy consistency. The results are mainly of physiological interest.

T. H. P.

Higher Fatty Acids in the Liver after Removal. **John B. Leathes** (Arch. exp. Path. Pharm., Suppl., 1908, 327—336. Compare Abstr., 1904, ii, 355).—A full account of a research previously published, with a description of further experiments on the same lines. The increase of fatty acids previously noted does not invariably occur, but no light can be at present thrown on the nature of the processes involved.

W. D. H.

The Formation of Uric Acid in the Liver of Birds. **Ernst Friedmann** and **H. Mandel** (Arch. exp. Path. Pharm., Suppl., 1908, 199—207).—The experiments recorded were made by perfusing the surviving liver of the goose with various mixtures. If uric acid is added to the perfusion fluid, none is retained or destroyed by the liver. If urea and sodium lactate or malonate are added, there is no increase in uric acid formation. Uric acid formation in the bird's liver is therefore not the simple synthesis it has been considered to be.

W. D. H.
Action of Certain Gases on Autolysis. Luigi Bellazzi (Zeitsch. physiol. Chem., 1908, 57, 389—394).—Carbon dioxide favours, and oxygen is indifferent, or feebly inhibitory, towards, autolysis of the liver.

Decomposition of Caffeine by Extract of Ox-Liver. Y. Kotake (Zeitsch. physiol. Chem., 1908, 57, 378—381).—Extract of ox-liver decomposes caffeine into xanthine, hypoxanthine, l-methylxanthine, and paraxanthine. The removal of the methyl groups is prevented by boiling the extract, or by the use of such protoplasmic poisons as toluene or chloroform. The action is therefore attributed to a ferment.

Action of Drugs on the Mammalian Uterus. Harold J. Fardon (Bio-Chem. J., 1908, 3, 405—411).—The investigation of a number of drugs shows that the reaction of the uterus is that of a plain muscular organ supplied by sympathetic nerves, of both inhibitory and augmentative nature. Pregnancy and nicotine alter the relative influence of the two sets of fibres.

Inosite [in Flesh]. Franz Rosenberger (Zeitsch. physiol. Chem., 1908, 57, 464—467. Compare Abstr., 1908, ii, 873).—One factor in the presence or not of inosite, or of its precursor, inositogen, in flesh appears to be the time of year, which, as is well known, also affects the quantity of glycojen.

Hydrolysis of Fish Muscle. Thomas B. Osborne and Frederick W. Heyl (Amer. J. Physiol., 1908, 23, 81—89).—The results are compared with those previously published in relation to chicken muscle in the following table, where the figures show percentages of cleavage products:

The most marked difference is seen to be in the percentage yield of glutamic acid.

Cholesterol in Ox-Bile. Ernst Salkowski (Zeitsch. physiol. Chem., 1908, 521—523).—Cholesterol can be easily prepared from the dried
bile of commerce. Previous saponification is unnecessary. The view is held that cholesterol occurs as such in bile, not as an ester.

W. D. H.

Quantitative Researches on the Exhalation of Alcohols. JULIUS POHL (Arch. exp. Path. Pharm., Suppl., 1908, 427–434).—The result of the experiments recorded is that alcohols of higher boiling points (tert.-amyl alcohol; isopropyl alcohol) are exhaled with the breath to a greater degree than those of lower boiling point (ethyl alcohol; methyl alcohol). This unexpected result cannot yet be explained.

W. D. H.

The Distribution of Nitrogen amongst the Various Products in Human Urine. LOUIS C. MAILLARD (Compt. rend., 1908, 147, 710–712).—The mixed urine from ten men of from 22–25 years of age was examined on six consecutive days. Of the total nitrogen excreted, 5.73% was in the form of ammonia, 81.29% in that of urea, 1.65% in that of purine compounds, 1.43% in that of uric acid, 0.22% in that of purine bases, and 11.15% in other forms of combination (creatinine, oxyproteic acids, urochrome, hippuric acid, amino-acids, etc.). The proportion of nitrogen to phosphorus was as 9:1.37. Muscular work was without appreciable influence on the total nitrogen excretion, although there was a slight diminution of urea, an undoubted increase in phosphates, and a slight increase in the nitrogen in the undetermined forms.

S. B. S.

The bases isolated from the precipitate in the first method were creatinine and as-dimethylguanidine, the latter of which was obtained as the crystalline aurichloride, m. p. 144°.

The precipitate obtained according to the second method contained creatinine and methylguanidine, the latter of which was isolated as its aurichloride, m. p. 198°. It has been shown that the methyl- and dimethyl-guanidines are not produced by the action of hydrochloric acid on creatinine.

When the third method of precipitation was used, all the creatinine is removed, as the filtrate no longer gave Weyl's reaction. The bases isolated from the precipitate were creatinine, methylguanidine, vitiatine, histidine, a base, C_{15}H_{36}O_{18}N_{8}, similar to some of the protamines, and a base, C_{5}H_{7}O_{2}N_{3}, similar to histidine. The last base was isolated as its picrolonate, C_{5}H_{7}O_{4}N_{3}C_{16}H_{3}O_{4}N_{4}, which crystallises in short needles, decomposing at 244°. The base gives a red coloration with alkali and copper sulphate, and also a dark red colour with an alkaline solution of diazobenzensulphonic acid.

Iminazole derivatives are found in the urine of most animals, but
herbivorous animals produce larger quantities of these compounds than do the carnivora.

The Regular Occurrence of Indole in the Distillate of Normal Urine. Max Jaffe (Arch. exp. Path. Pharm., Suppl., 1908, 299—308).—Indole is constantly found in the urine of man and other animals examined. The methods of obtaining and identifying it are given in full, the differences in quantity in various animals noted, and the conditions in which indole derivatives occur discussed.

W. D. H

Urinary Pigments derived from Indole. Alberico Benedicenti (Arch. exp. Path. Pharm., Suppl., 1908, 64—74. Compare Abstr., 1907, ii, 980).—After subcutaneous administration, 5-methylindole appears in the urine as dimethylindigotin; 2:5-dimethylindole forms a red colouring matter, and α-naphthindole yields a reddish-brown coloration, changing later to bluish-green.

G. B.

Excretion of Urobilin in Disease. N. F. Surveyor (Bio-Chem. J., 1908, 3, 439—448).—From an examination of 500 specimens of urine in health and disease, the conclusion is drawn that there is no correspondence between the amount of urobilin excreted and the amount of ethereal sulphates in the urine. Urobilin formation is therefore not the result of intestinal putrefaction. Disease of the liver also does not seem to be responsible for its appearance. The method adopted for the estimation of urobilin is the depth of the absorption band in an amyl-alcoholic extract of the urine, and so far as any conclusion can be drawn from the inconstant results found in most diseases, it appears that conditions that lead to hæmoglobin destruction are those most likely to produce increase of the urinary urobilin.

W. D. H.

Microchemical Changes occurring in Appendicitis. Owen T. Williams (Bio-Chem. J., 1908, 3, 391—401).—The author considers that intestinal sand (Abstr., 1907, ii, 906) consists largely of calcium salts (soaps) of saturated fatty acids. These soaps are not so easily absorbed as those derived from unsaturated fatty acids.

Action of Radium Emanations [in Diabetes]. E. Poulsson (Arch. exp. Path. Pharm., Suppl., 1908, 443—448).—It is well known that many mineral waters contain radium. Cases of diabetes were treated with radioactive water. In two severe cases, no good was done; in a third case, where the disease was not so malignant, the excretion of sugar was lessened, although whether this was due to the water is uncertain.

W. D. H.

The Degradation of Fatty Acids in Diabetes Mellitus. Julius Baer and Leon Blum (Arch. exp. Path. Pharm., 1908, 59, 321—330).—It has been shown previously (compare Abstr., 1907, ii, 285) that isovaleric acid gives rise to β-hydroxybutyric acid in severe cases of diabetes mellitus, and leucine acts in a similar way; no
great difference could be detected in the relative amounts excreted. Experiments were made in mild cases of the disease, and it was found that isovaleric acid exerted but little influence on the excretion of the hydroxybutyric acid; $n$-butyric and hexoic acids caused, however, an increased output. Similar results were not obtained in all the cases investigated.

S. B. S.

The Influence of Muscular Work on the Excretion of Sugar in Pancreas Diabetes. Y. Seo (Arch. exp. Path. Pharm., 1908, 59, 341—363).—Experiments were carried out on dogs which had been either wholly or partly deprived of the pancreas. The excretions of nitrogen and sugar were determined during periods of rest and periods of work, when the animals turned a treadmill. In animals in which the pancreas had only been partly removed, it was found that muscular work diminished the excretion of sugar. This was not the case, however, in animals on which total extirpation of the pancreas had been performed. In these cases, the ratio dextrose: nitrogen increased during the periods of work. The conclusion is drawn that increased utilisation of sugar by muscular work can only take place when some functioning pancreas tissue remains in the organism.

S. B. S.

Acidosis in Pancreas Diabetes. Eduard Allard (Arch. exp. Path. Pharm., 1908, 59, 388—396).—Brugsch and others have maintained that acidosis is not found in cases of severe pancreas diabetes. The author cites, however, several experiments made with dogs deprived of the pancreas, in which a comparatively large output of $\beta$-hydroxybutyric acid was observed. The phenomenon of acidosis in these cases is, however, a very inconstant one, and it is suggested that it is due to secondary causes. The liver, or other parenchymatous tissue, in the advanced stages of the disease may have lost the power of degrading acetoacetic acid or acetone to simpler substances.

S. B. S.

Radioactivity of Goitrigenic Springs. Répin (Compt. rend., 1908, 147, 703—705. Compare this vol., ii, 796).—The author has measured the radioactivity of the water of fourteen springs, a well, and several torrents situated in districts where goitre is endemic. The springs issuing from faults at the base of high mountains were all found to be radioactive, whilst surface water and torrents fed by glaciers or snow were inactive. Torrent waters when without turbidity are preferred, and the people who use them are free from goitre. A goitrous family living in a non-goitrous district was employing a radioactive well water. The prevalence of goitre in mountainous districts, and the success of distilled water in treating it, also suggests a connexion between radioactive water and the disease. The radioactivity has the character of radiothorium.

R. J. C.

The Pathogenesis of Ochronosis. Oscar Gross and Eduard Allaret (Arch. exp. Path. Pharm., 1908, 59, 384—387).—The colouring of cartilage in the pathological condition known as ochronosis
is due to the same anomaly in metabolism that produces alcaptonuria, namely, the production of homogentisic acid, which is not destroyed in the organism. The cartilage appears to have the property of attracting this acid and converting it into a dark pigment, producing in this way a form of arthritis, designated by the authors arthritis alcaptonurica. Almagia has shown that in cartilage soaked in solutions of sodium urate, concretions are formed similar to those found in cases of gout, and the authors show that cartilage in nearly neutral homogentisic acid solutions acquires a dark colour similar to that observed in cases of ochronosis. Other tissue does not act in this way.

S. B. S.

A Case of Chronic Pentosuria. Riccardo Luzzatto (Arch. exp. Path. Pharm., Suppl., 1908, 366—377).—The urine of the patient (who has remained in good health for many years) contains generally 0·1% of l-arabinose. The amount is not affected by ingestion of large quantities of dextrose, sucrose, or starch, but is increased by galactose, by alkalis, and by intellectual work, and diminished by the ingestion of hydrochloric acid, and apparently also by excessive muscular labour. Pentosuria is therefore quite distinct from diabetes. In order to determine the reducing power of the urine, lead acetate is added, and, after filtration, ammonia; the basic lead precipitate formed carries down all the pentose, and is then redissolved in acid. G. B.

Contents of a Cystic Tumour of the Breast. Emil Zdarek (Zeitsch. physiol. Chem., 1908, 57, 461—463).—A complete analysis of the contents of a so-called butter-cyst of the mammary gland is given. It occurred in a woman, forty years of age, and had lasted twelve years before it was removed. It was about the size of an apple. It contained 48% of water, 38·6% of fat, 7·5% of fatty acids, 3% of coagulable protein, 1% of caseinogen, and 1·6% of ash. W. D. H.

Action of Barium Chloride, Adrenaline, and Peptone on the Vaso-motor Apparatus. L. Popielski (Arch. exp. Path. Pharm., Suppl., 1908, 435—442).—The three substances named all act on the peripheral vaso-motor mechanism. Barium chloride and adrenaline cause a rise of pressure by acting on the musculature; Witte's peptone causes a fall by acting on the nerve-endings in the vessels. The substance responsible for the activity of Witte's peptone is named vaso-dilatin, it is not a protein, nor is it choline, which when pure produces the opposite effect. Vaso-dilatin is also the substance which renders the blood incoagulable. W. D. H.

Action of Certain Narcotics on Nerve. Albrecht Bethe (Arch. exp. Path. Pharm., Suppl., 1908, 75—82).—The excitability of nerve and its reaction to the constant current (polarisation picture) go hand in hand. Solutions of chloral hydrate, ethylurethane, and phenylurethane, which abolish the excitability, also abolish the normal polarisation changes. If the dose of the narcotic is insufficient to completely abolish excitability, the polarisation changes are altered in like measure. When these changes are produced, immersion in
Locke's solution causes the nerve to recover. This reversibility is least easy to obtain after chloral hydrate. W. D. H.

—Certain tropinees containing a lactone group (Jowett and Hann, Trans., 1906, 89, 357; Jowett and Pyman, Trans., 1907, 91, 92), and possessing an atropine-like action, lose this action when they are converted into salts of the corresponding hydroxy-acids. After the addition of a molecular quantity of alkali hydroxide, this conversion occurs relatively slowly towards the end of the reaction, and the gradual change can be demonstrated pharmacologically.

Behaviour of Sodium Salicylate in the Organism. ALESSANDRO BALDONI (Arch. exp. Path. Pharm., Suppl., 1908, 54—63).—Sodium salicylate, when administered to dogs, is mostly excreted unchanged in the urine, but a small portion is converted into two crystalline derivatives with acid properties, both yielding a blue coloration with ferric chloride and having a strong reducing action. Of these, one, m. p. 169—170°, has the composition $C_{16}H_{10}O_{5}$N; the other, m. p. 187—188°, has the composition $C_{16}H_{14}O_8$. Salicyluric acid, which is found in human urine after ingestion of sodium salicylate, cannot be detected in dogs’ urine.

Pharmacological Significance of Twin Ethyl Groups. SIGMUND FRÄNKEL (Arch. exp. Path. Pharm., Suppl., 1908, 181—187).—In order to test the hypothesis, that the hypnotic action of such drugs as veronal (diethylbarbituric acid, $CO<\text{NH-}CO\text{C}Et_2$) is due to two ethyl groups attached to the same carbon atom of the ring, the author has examined tetra-, penta-, and hexa-ethylphloroglucinol, and also the hexamethyl derivative. None of these substances has a hypnotic action, but they produce strychnine-like convulsions.

Pharmaco-dynamic Characters of Coumarin. ALEXANDER ELLINGER (Arch. exp. Path. Pharm., Suppl., 1908, 150—163.)—The toxic action of cantharidin on the kidneys suggested the examination of other substances with a lactone structure, and coumarin was selected. In rabbits, albuminuria may occur, but only to any extent when the urine is acid. The injury to the kidneys, even in large doses, is never serious. Coumarín, however, in frogs causes deep narcosis, owing to its action on brain and cord; the centres affected include those governing cardiac inhibition and respiration, but the vaso-motor centre is not affected. In rabbits it is, in suitable doses, a harmless narcotic, and has no effect on the heart; large doses injected intravenously paralyse the respiration and produce death. In dogs, also, it is a narcotic, and usually produces vomiting. In large doses it kills them, but without the characteristic symptoms noticed in rabbits. This difference in action is probably related to a difference in
excretion in the two animals, but this part of the work is still in progress.

W. D. H.

Behaviour of Atropine in Various Animals. Max Cloetta (Arch. exp. Path. Pharm., Suppl., 1908, 119—125).—Atropine appears to be destroyed in the brain and liver; this is most marked in the rabbit’s brain, and least in the cat. This appears to be related to what is termed the “vital reaction difference” of the nervous tissues of various animals, and is not yet explicable on a chemical or physical basis.

W. D. H.

Action of Caffeine on Frogs. Carl Jacobi and Golowinski (Arch. exp. Path. Pharm., Suppl., 1908, 286—298).—The relative difference in the action of caffeine on the two species of frog (Rana esculenta and R. temporaria) has been attributed to differences in the excitability of the spinal cord. The present research deals mainly with the difference between the muscles of the two species. The difference is mainly one of elasticity and extensibility, and this, as well as the different behaviour of caffeine towards them appears to depend on the sarcolemma of the muscular fibres, and the amount or character of its lipoids.

W. D. H.

The Fate of Synthetic Muscarine in the Animal Body. Hermann Fühner (Arch. exp. Path. Pharm., Suppl., 1908, 208—213).—If muscarine is given subcutaneously to tortoises, it is again obtainable in the urine during the next few days in active form, and but little, if at all, altered in amount. The same is true for curarine.

W. D. H.

Poisons of Amanita Phalloides. John J. Abel and William W. Ford (Arch. exp. Path. Pharm., Suppl., 1908, 8—15. Compare Abstr., 1907, ii, 192).—Further details are given of the properties and actions of the two poisons contained in this fungus, namely, the hemolysin, which is a glucoside containing pentose, and the toxin. The hemolysin is easily destroyed by the gastric juice, so that, if taken by the stomach, it does not manifest its hemolytic properties.

W. D. H.

Action of Atoxyl on the Animal Body. J. Igersheimer (Arch. exp. Path. Pharm., Suppl., 1908, 282—285).—Although sodium p-amino-phenylarsenic acid may have its proper sphere of action in dealing with diseases due to protozoa (trypanosomiasis, syphilis, etc.), it should be recognised that its other name, atoxyl, is an illusory one, and in man it produces effects on the nervous, excretory, and alimentary system. Details are given of its toxic action on a number of dogs and cats.

W. D. H.

Action of Poisons on Enzymatic Processes. Karl G. Santesson (Arch. exp. Path. Pharm., Suppl., 1908, 469—481).—It is suggested that the harmful influence of such poisons as hydrocyanic acid on the heart and on plant life is due to interference with intra-
cellular enzymes, the action of which forms the basis of the activity of living cells. In support of this view, experiments are recorded with muscle extract, and the action of the catalase in it was measured by the evolution of gas which occurs when mixed with hydrogen peroxide. This action is favoured by dilute alkali, hindered by dilute acid, by hydrocyanic acid, and also by manganese sulphate in decinormal solution; but in concentration N/1000 the development of gas is slightly increased; the favouring action of dilute solutions of manganese salts on other enzymatic processes is well known.

W. D. H.

Poisoning with Potassium Chlorate. L. Riess (Arch. exp. Path. Pharm., Suppl., 1908, 460—468).—The haemolysis which follows poisoning with potassium chlorate is of a specially pernicious character, and differs from other cases of haemolysis in that the corpuscles are broken up, so that irregular clumps of haemoglobin are formed. The urinary tubules become filled with similar particles, although how they pass the renal epithelium is a difficulty; these tubules, especially in chronic cases, get filled with these particles, which blend so as to form casts of the tubules.

W. D. H.

Post-mortem Action of Corrosive Poisons in the Stomach. Erich Harnack and Hermann Hildebrandt (Arch. exp. Path. Pharm., Suppl., 1908, 246—252).—In forensic medicine, the degree of action of a caustic poison after death is sometimes raised. It is shown by experiments on cats that their destructive action on the gastric mucous membrane is more marked after death than during life. The action of potassium cyanide on the blood pigment also occurs post-mortem, but absorption of ammonia from the stomach only takes place during life.

W. D. H.

Chronic Oleic Acid Poisoning. Edwin S. Faust (Arch. exp. Path. Pharm., Suppl., 1908, 171—175).—The idea that the anaemia in those afflicted with the tape-worm, Bothriocephalus, is due to oleic acid contained as a cholesterol ester in the worm acting as a haemolytic poison, led to the present research, in which it is shown by experiments on rabbits and dogs that oleic acid administered by the mouth or subcutaneously over long periods of time does act as a haemolytic agent in the same way as it does in vitro; the red corpuscles are diminished in number, and the haemoglobin is lessened in amount.

W. D. H.

So-called Antitoxic Power of Animal Tissues towards Strychnine. Paul Pellacani and Folli (Arch. exp. Path. Pharm., Suppl., 1908, 419—426).—Proofs are adduced that the tissues do not possess the power of destroying strychnine; practically the whole of it (98%) can be recovered from the tissues many hours after its introduction.

W. D. H.
Chemistry of Vegetable Physiology and Agriculture.

Estimation of the Reducing Power of Bacteria and Animal Organs. Heinrich Wichern (Zeitsch. physiol. Chem., 1908, 57, 365—377). An important distinction between different microorganisms is their relative reducing powers, and most methods hitherto employed are defective from the quantitative aspect. It is, however, possible to obtain good results with certain coloured substances, the colour of which disappears on reduction; of these, methylene-blue appears to be the best. Still better results are obtained with ferric chloride and titration with titanium trichloride. This is illustrated by the experiments recorded with various bacteria. The method as applied to pieces of organs is not so useful, although fairly concordant results are obtained with extracts of organs. It is suggested that the same method might be employed for the estimation of the activity of oxydases.

W. D. H.

Bacterial Formation of Sulphates in Sewage Purification. Ch. Rouchy (J. Pharm. Chim., 1908, [vi], 28, 439—444).—The opalescence or milkiness of effluents from inefficient bacterial sewage beds is due to the presence of finely-divided sulphur. In the limpid effluents from beds which are working properly, the sulphur has been entirely converted into sulphuric acid, which, reacting on the carbonates in the sewage, is converted into sulphates. This formation of sulphuric acid is, the author thinks, due to the oxidising action of special bacteria, analogous to the nitrifying organisms. T. A. H.

Oxidation by means of Moulds. Reginald O. Herzog and A. Meier (Zeitsch. physiol. Chem., 1908, 57, 35—42. Compare Harden, Trans., 1903, 83, 424).—Cultures of Penicillium glaucum were grown in dilute beer wort, and when the evolution of carbon dioxide had reached a constant value, a solution of the ammonium salt of a hydroxy-acid was added. The evolution of carbon dioxide was increased considerably, and each experiment was continued until the evolution had fallen again to the normal value for the medium. In this way, the carbon dioxide due to the decomposition of the hydroxy-acid could be calculated. The following acids were readily attacked: lactic, tartaric, malic, mandelic, β-hydroxybutyric, and in every case the amount of carbon dioxide evolved was considerably in excess of that calculated for the amount of acid destroyed.

Glycollic, citric, pyruvic, and hydroxyisobutyric acids were not affected.

The conclusion is drawn that the process is one of oxidation, but is accompanied by another unknown reaction, which also gives rise to carbon dioxide.

It has been shown that, when the organism has been destroyed by acetone or methyl alcohol, it can still decompose the hydroxy-acids, thus indicating that the reaction is due to an oxidising enzyme. The
activity of the dead cells is not so marked as that of the living, and ceases after some thirty-six hours. — J. J. S.

Conversion of Cinnamic Acid into Styrene by means of Moulds. REGINALD O. HERZOG and O. RIPKE (Zeitsch. physiol. Chem., 1908, 57, 43—45. Compare Oliviero, Abstr., 1906, ii, 623).—Styrene is formed when Aspergillus niger is grown in dilute beer wort containing ammonium cinnamate (0·25% solution). The amount of hydrocarbon formed can be determined by aspirating sterilised air through the liquid, and then passing it through ten bulbs containing carbon disulphide. The styrene is weighed as its dibromide.

Attention is drawn to the importance of this type of reaction for the explanation of the formation of mineral oil deposits. — J. J. S.

Transformations of the Chromogenic Matter of Grapes during Maturation. J. LABORDE (Compt. rend., 1908, 147, 753—755).—It has been shown previously (this vol., ii, 774) that the colouring matter of red grapes can be artificially produced from the cenotannin of the unripe grapes. The object of the present work is to discover how the transformation is effected naturally. The tannins exist in the green pellicles in two forms: (1) soluble in strong alcohol, (2) insoluble in this solvent, the latter being the greater in amount. By determination of the amounts of these tannins in various species of red and white grapes, in varying states of maturity, by means of a colorimetric method described, it is shown that the total quantity of tannin matter diminishes, the proportion of the soluble tannin increases, and that of the insoluble tannin diminishes, during ripening. It is during this change of the insoluble into soluble tannin that the colouring matter of the red grapes appears. Colorimetric examination of the hydrochloric acid solution from the pellicles of grapes just commencing to ripen, before and after heating in an autoclave, shows that they contain untransformed cenotannin; with the ripe grapes this is not observed. The cenotannin in the wine must therefore proceed from other solid parts. The soluble tannin obtained from the pellicles of ripe white grapes gives only an insoluble, brown colouring matter when heated with 2% hydrochloric acid in an autoclave. The change in solubility of the tannin is probably due to diastatic action, and this raises the question whether it is an enzyme which transforms the cenotannin into the colouring matter of red grapes; if so, this enzyme must be absent from the white grapes. All attempts to find such an enzyme have, however, proved unsuccessful. — E. H.

Carbohydrates of Coelococcus and Phytelephas. SERGIUS IVANOFF (J. Landw., 1908, 56, 217—228).—Ground Coelococcus shavings, when hydrolysed with 6% sulphuric acid, yielded 20% of mannose; Phytelephas macrocarpa gave 37%. No other hexose was produced in appreciable quantity. Both substances yielded arabinose when boiled with 2—3% sulphuric acid; xylose could not be detected. Mannose was found to be present in two modifications, as hemicellulose and as mannocellulose. — N. H. J. M.
Indole in Flowers. F. WEEHUIZEN (Pharm. Weekblad, 1908, 45, 1325—1329).—Indole can be detected in the white flowers of Murraya exotica by the action of vanillin or p-dimethylaminobenzaldehyde on the alcoholic extract in presence of concentrated hydrochloric acid. Each reagent produces a red coloration, that with p-dimethylaminobenzaldehyde being more intense in presence of sodium nitrite. Since phloroglucinol answers to the same test when it is present, the vapour exhaled from the flowers should be allowed to come into contact with the reagents.

A. J. W.

Abnormal Biochemical Products of the Rue Anemone. FREDERICK S. BEATTIE (Amer. Chem. J., 1908, 40, 415—428.)—Fasciated specimens of rue anemone (Syndesmon thalictroides) contain about 20% of methyl and ethyl isocarbostyril-3-carboxylates and 3-methylquinoline-4-carboxylic acid. These substances are not found in the normal plant.

J. C. C.

Preparation of Pure Chitin from Boletus edulis. EMIL SCHOLL (Monatsh., 1908, 29, 1023—1036).—The membranes of Boletus edulis consist chiefly of chitin in loose combination with carbohydrates. It has been found possible to prepare pure chitin from this fungus to the extent of 5 to 6% of the dried plant by alternate treatment with boiling water and boiling 10% aqueous potassium hydroxide. The chitin so obtained is chemically identical with animal chitin, and is, unlike Winterstein's fungus-cellulose (Abstr., 1896, ii, 210), completely insoluble in concentrated alkalis. It yields about 78% of crystalline glucosamine hydrochloride when hydrolysed with hydrochloric acid.

W. H. G.

Peptolytic Ferments in Germinating and Ungerminated Seeds of Various Plants. EMIL ABDERHALDEN and DAMMHAHN (Zeitsch. physiol. Chem., 1908, 57, 332—338).—The existence of proteolytic enzymes in plants has been established by the work of Schulze and Winterstein. Schittenhelm found also peptolytic ferments in seeds, and this observation is confirmed; extracts of the seeds of wheat, maize, barley, and lupins produce splitting of glycyl-l-tyrosine if the seeds have germinated. In the resting stage, peptolytic ferments are absent.

W. D. H.

Assimilation and Elimination of Nutrients by Oats at Different Periods of Vegetation. L. SEIDLER and ALBERT STUTZER (J. Landw., 1908, 56, 273—278).—Pot experiments with oats in two different soils (a heavy loam mixed with gravel and a chalky gravel mixed with peat), manured with superphosphate and sodium nitrate and with varying amounts of potassium chloride. The plants were analysed (1) four weeks after sowing the seed, (2) when the ears began to form, (3) at the period of full flower, and (4) when the ripening was complete.

As regards nitrogen, it was found that from 50 to 60% of the total amount assimilated was taken up in the first four weeks, and that the ripe plants contained from 6 to 26% less nitrogen than at the third
period. The highest amounts of potassium were also found in the third period, the losses during ripening increasing, with some exceptions, with the amount of potassium chloride applied.

Sodium, calcium, and phosphoric acid seem to be retained by the plants to the end; slight losses of calcium occasionally took place between the third and fourth periods.

N. H. J. M.

Influence of Different Manurial Conditions on the Assimilation of Nutrients and the Structure of Plants. Max Wagner (Landw. Versuchs-Stat., 1908, 69, 161—233).—Two series of pot experiments in which mustard, buckwheat, barley, and oats were grown under different manurial conditions. In the second series, plants were taken up and analysed at four periods of growth (May 9 and 29, June 25 and July 13).

As regards the final amount of growth above ground, both the oats and the barley, which ripened completely, generally showed a loss, especially when insufficiently manured. Deficiency of nutrients, especially nitrogen, resulted in a higher relation of roots to above ground growth.

A deficiency of phosphoric acid in soil otherwise sufficiently manured reduced the yield of barley most, then oats, buckwheat, and mustard. When potassium was deficient, barley again suffered most, then oats and mustard, and lastly buckwheat.

Whilst the buckwheat, which remained green to the fourth period, continued to take up the different nutrients to the end, the oats, barley, and mustard showed losses of nitrogen, potassium, and phosphoric acid at the final period.

The relation of grain to straw was considerably affected by the conditions of manuring. In the case of barley, a low relation of grain was most marked when potassium was deficient, whilst with oats, deficiency of nitrogen caused the greatest reduction.

N. H. J. M.

Amount of Nutrients Utilised by Sugar-Beet in the First Year and its Relation to the Amount of Sugar in the Roots. Karl Andrlik and Josef Urban (Zeitsch. Zuckerind. Böhm, 1908, 33, 83—94. Compare ibid., 1906, 31, 149; 1907, 32, 559).—The amount of phosphoric acid assimilated by sugar-beet depends on the manuring and the amount present in the soil, on the rainfall, and on the seed. With a yield of 400 quintals of roots, the amount of phosphoric acid taken up under normal conditions varied from 51.7 to 87.8 kilos., whilst in a dry season the average amount was 48.6 kilos.

The amount of phosphoric acid required to produce 100 parts of sugar also varies according to manurial and climatic conditions. The results of various experiments made from 1902 to 1905 showed that the average amount is 0.97 part of P2O5, the amount deposited in the roots being 48.4% of the total.

N. H. J. M.

Digestibility of Hay from Water Meadows as Compared with Ordinary Hay. Konrad Friedländer (Landw. Versuchs-Stat., 1908, 69, 245—258).—The hay from water meadows is characterised
Studies on the Soils of the Northern Portion of the Great Plains Region: Nitrogen and Humus. Frederick J. Alway and Robert S. Trumbull (Amer. Chem. J., 1908, 40, 147—149. Compare Abstr., 1907, ii, 294).—Determinations of total nitrogen, soluble humus, and the nitrogen in the soluble humus in nineteen comparatively heavy soils and one sandy soil from Saskatchewan and Alberta. The percentages of total nitrogen are fairly high in all the soils except the sand, whilst the humus is rather low, although much higher than in the arid soils of California. The proportion of the total nitrogen present in the form of humus is decidedly low. The percentage of nitrogen in the humus is not markedly different from that of soils from humid regions.

The results seem to indicate that the surface soils of the semi-arid portions of Western Canada have the characteristics of humid regions, whilst the sub-soils show the peculiarities of other arid regions.

N. H. J. M.

Isolation of Dihydroxystearic Acid from Soils. Oswald Schreiner and Edmund C. Shorey (J. Amer. Chem. Soc., 1908, 30, 1599—1607. Compare this vol., ii, 889).—Four out of six more or less unfertile soils were found to contain dihydroxystearic acid, identical with the one obtained from elaidic acid (Saytzeff, Abstr., 1886, 140). The soil which yielded most of the substance was a grey silt loam from Tennessee, which had been under cultivation for more than fifteen years chiefly in cotton. The soil contains organic matter 3·26, and nitrogen 0·16%. The amount of fairly pure substance obtained from 1 kilo. of soil was about 0·05 gram; the amount actually present is probably far greater.

As regards the toxicity of dihydroxystearic acid, experiments with wheat seedlings show that as little as 20 parts per million is distinctly injurious; 100 parts per million reduced the weight to 53%, whilst 200 parts per million (approximately a saturated solution) had about the same effect. Practically the same results were obtained with dihydroxystearic acid, prepared from elaidic acid, and with the isomeric acid from oleic acid, the weight being reduced to about half of that in the control experiment, and the plants being killed in twelve to fifteen days.

The Takoma soil previously examined (loc. cit.), which also contains dihydroxystearic acid, seems to be a good medium for fungi. Rootlets of oak trees growing in the soil were found to be infested with mould, and when freed from soil yielded small quantities of the acid. The conclusion is drawn that the dihydroxystearic acid is produced by the moulds, perhaps by the decomposition of lecithins.
into oleic acid, conversion of oleic acid by nitrous acid into elaidic acid, and oxidation of the latter by enzymes or micro-organisms.

N. H. J. M.

Ammonia Question. Paul Ehrenberg (Landw. Versuchs-Stat., 1908, 69, 259—294. Compare this vol., ii, 60).—Experiments on the production of basic and acid reactions in peaty soil, by application of nitrogen in the form of potassium or sodium nitrate and ammonium salt respectively, and on the effect of the reactions on different plants. Experiments were also made in which ammonium sulphate was applied both with and without calcium carbonate.

As an example of the effect of the two forms of nitrogen (in absence of calcium carbonate) on the growth of plants in an acid soil, it is shown that maize, sorghum, barley, and white mustard during the first periods of growth cause the acidity of the soil to be neutralised when manured with nitrate, and then produce normal growth. At the same time, the assimilation of potassium and other bases tends to maintain the change of reaction within certain limits. The same plants, manured with ammonium sulphate, were able, with the exception of mustard, to make a start under the conditions of slight soil acidity, but after reaching a certain point fell off, owing to the increased acidity resulting from the sulphuric acid of the ammonium salt. Mustard is the most sensitive to ammonium salts, and maize the least sensitive, owing probably to the greater amount of soil it produces.

N. H. J. M.

Old and New Nitrogenous Fertilisers: Calcium Cyanamide, Calcium Nitrate, Ammonia Sulphate, and Sodium Nitrate. Vittorio Nazari (Atti R. Accad. Lincei, 1908, [v], 17, ii, 334—342).—The author has investigated the influence of various factors on the fertilising value of calcium cyanamide, and has carried out experiments on the comparative values of calcium cyanamide, calcium nitrate, ammonium sulphate, and sodium nitrate as fertilisers. The crop used, in all cases, was wheat.

The results show that the value of calcium cyanamide is greatly enhanced by the presence in the soil of organic matter in the form of stable manure. The cyanamide acts most beneficially at about 20 cm. below the surface of the soil, and at a depth of 5 cm. gives much less favourable results than at a depth of 35 cm. The best fertiliser to use in association with calcium cyanamide is bone superphosphate, partly owing to the fact that it contains a certain proportion of readily fermentable matter, which serves to nourish the micro-organisms; also, admixture of the cyanamide with gypsum gives better results than admixture with lime, owing to the action of the calcium sulphate on the soil constituents containing insoluble potassium compounds, and to its stimulating action on many of the lower forms of plant life. On treating the soil with equal amounts of nitrogen in the form of the various fertilisers, the best and approximately identical results were obtained with calcium nitrate, ammonium sulphate, and sodium nitrate, calcium cyanamide yielding a considerably inferior crop.

T. H. P.
Danger of Employing Salts of Arsenic in Agriculture. W. Mestrezat (J. Pharm. Chim., 1908, [vi], 28, 393—397).—Wines manufactured from untreated vines are found to contain 0·000005 to 0·000008 gram of arsenic per litre, whilst those from vines which have been cultivated on the same soil and in the same manner as the preceding, except that they have been treated three times with various arsenical preparations (as insecticides), contain 0·000020 to 0·000025 gram of arsenic per litre. The danger from this cause is accordingly negligible. Inappreciable quantities of arsenic are found to be inhaled by workmen who have to prepare the arsenic salts for use, whilst the quantities settling on their hands and faces (0·0007 to 0·0012 gram) are probably innocuous.

Analytical Chemistry.

New Burette Clamp. Gustav Müller (Zeitsch. angew. Chem., 1908, 21, 2318—2319).—To a retort stand with a tripod base are fixed one or more clamps so constructed that they may be moved and turned both horizontally and vertically. Hence it is immaterial whether the stand is perfectly level, for the burettes may be always properly adjusted.

A retort stand with the rod fixed in the centre of the oblong base may also be used; the rod should consist of two parts, which may be unscrewed if desired. The base is provided with a hole, so that it may be attached to the wall; the clamps are then fixed to the protruding rod. From the rod may be suspended a variety of laboratory sundries, such as towels, brushes, etc., so as to economise space.

Rapid Method of Qualitative Analysis. W. Branch Pollard (Chem. News, 1908, 98, 211).—One part of the finely-powdered substance is mixed with 1 part of vaseline and 5 parts of sodium peroxide. The mixture is placed on a thick iron plate, or in the cavity of a scorifying mould, and ignited by means of a match or a Bunsea burner. The fused mass is extracted with water, and both the soluble and insoluble matter tested as usual. The soluble portion contains, in the highest state of oxidation, those elements which form soluble sodium salts; the insoluble portion contains the oxides and carbonates of the other metallic elements.

A special test should be made for mercury and sodium. The method is more particularly suited for examining ores and minerals in the field.

Detection of Hydrogen Peroxide in Milk. W. Percy Wilkinson and Ernst R. C. Peters (Zeitsch. Nahr. Genussm., 1908, 16, 515—517).—The reaction described by Feder (Abstr., 1908, ii, 318) is shown by
the authors' experiments to depend on the actual quantities of hydrogen peroxide and formaldehyde present, and also on the proportion of these two substances to each other. The strongest reaction is obtained when from 0·004 to 0·013% of formaldehyde and about 0·005% of hydrogen peroxide are present in the milk. If the amount of hydrogen peroxide is increased to 0·5%, a coloration is not obtained. Ferric salts, nitrates, etc., also influence the reaction, so that a positive reaction is not a definite proof of the presence of hydrogen peroxide. The test proposed by the authors (Abstr., 1908, ii, 907) for distinguishing between raw and heated milk may be applied conversely to the detection of hydrogen peroxide; it is not affected by the presence of nitrates or ferric salts.

W. P. S.

With 1:4-dichloronaphthalene tetrachloride, 3:4-dichlorophenol, and p-bromoaniline, this method gives low results, whilst with p-dibromobenzene and iodoform good results are obtained.

The method is only applicable to substances which burn quietly with the sodium peroxide, and give no smoke or flame outside the crucible. As it is impossible to tell beforehand if this will be the case, and as there is no definite limit between quiet and vigorous combustion, the method is not to be recommended.

T. H. P.

Kjeldahl's Method. Ernst Salkowski (Zeitsch. physiol. Chem., 1908, 57, 523—526).—Some practical details in the employment of this method are given as the result of the author's experience. Among other points, the omission of the addition of mercuric oxide is recommended.

W. D. H.

Micro-chemical Reactions of Arsenic Applicable to Medico-Legal Investigations. Georges Denigès (Compt. rend., 1908, 147, 596—597).—A description of the technique is given for identifying arsenic by microscopical methods, the reagents employed being silver nitrate in solutions acidified by acetic acid, and in ammonia solutions. The reactions are carried out with a drop of arsenical liquid, which has been evaporated to dryness with certain precautions, on an object glass.

S. B. S.

Mercurous Nitrate as a Microchemical Reagent for Arsenic. Georges Denigès (Compt. rend., 1908, 147, 744—745. Compare preceding abstract).—The reagent is prepared by triturating crystallised mercurous nitrate (10 grams) with nitric acid (D 1·39, 10 c.c.) and adding water (100 c.c.). A small drop of the solution (in nitric acid) to be tested is evaporated to dryness on a glass plate by a gentle heat, and the residue treated with a drop of ammonia, which is also evaporated. To the residue, when quite cold, a drop of the mercurous reagent of a volume insufficient to completely cover it is added.
After two minutes, the drop of reagent is spread over the entire residue by means of a very finely-pointed glass rod, care being taken not to scratch the glass and to keep the rod in a continuous circular motion for 20—30 turns. After another two minutes, if arsenic is present, examination under the microscope (magnifying 40—50 or 100 diameters) reveals thick macles and crystallites, often arranged in a double fan-shape and coloured brownish-yellow, and groups of almost colourless tablets with rounded ends. When the residue is very small, only an extremely small drop (not more than 1—2 mm. diameter) must be used. The test can only be effected successfully by exact attention to all the above details.

E. H.

Simplified Apparatus for the Estimation of Carbon in Iron. Theo. Grzeschik (Chem. Zeit., 1908, 32, 1092).—An improvement of the apparatus generally used. Close to the end of the inner tube of the condensing arrangement is sealed a concave disk, on which is placed the sample, and when the condenser is placed in the flask the disc should dip slightly into the chromic acid mixture. After transmitting a current of purified air and connecting the apparatus with the train of absorbers, heat is applied with a small flame, and, owing to the disc, a more even distribution of heat is effected. Instead of using a breakable glass tube for connecting the condenser with the water supply, an indiarubber tube is substituted. The distance between the condenser and flask is about 2 mm. The acid rises to a considerable height in the tube, but there is no danger of loss.

L. de K.

A Boat Funnel. H. Stoltzenberg (Zeitsch. angew. Chem., 1908, 21, 2271).—To facilitate filling the boat used for combustions, the author describes a nickel funnel made the shape and length of the boat and having a narrow slit underneath. This funnel is supported over the boat, which stands on a small nickel tray, and it allows of the substance being evenly distributed along the boat in an expeditious manner; if overfilled, the substance may be collected from the nickel tray.

J. V. E.

Apparatus for the Estimation of Carbon Dioxide, etc. M. Emmanuel Pozzi-Escot (Bull. Assoc. chim. Sucr. Dist., 1908, 26, 267—271).—The piece of apparatus described consists of a flat-bottomed flask provided with a hollow glass stopper, through the centre of which is fused the stem of a tapped funnel; the latter serves as a reservoir for the dilute acid, or other reagent, used in the estimation. A narrow glass tube extends from the stopper of the bottle to the top of the funnel, and a second tube leading from the stopper serves as the delivery tube of the apparatus. The top of the funnel is closed by means of a stopper provided with a small hole, which, on turning the stopper, is brought opposite a similar hole in the neck, so that the pressure in the flask may be equalised when necessary. The apparatus may be used for the estimation of carbon dioxide in carbonates, nitrogen in urea and ammonia (by using the sodium hypobromite method), and in the analysis of hydrogen peroxide, persulphates, etc.

W. P. S.
Separation of the Alkali Metals in the Electrolytic Way. Jacob S. Goldebaum and Edgar F. Smith (J. Amer. Chem. Soc., 1908, 30, 1705—1711).—In earlier papers (Abstr., 1907, ii, 574, 988), it has been shown that halide salts of various metals, and particularly those of the alkalis and alkaline earths, can be readily analysed electrolytically with the aid of a mercury cathode and a rotating silver anode. Results are now recorded which have been obtained with ammonium chloride, bromide, and thiocyanate, and the chlorides of caesium, rubidium, lithium, and which prove the accuracy of the method.

An account is given of experiments on the separation of the alkali metals. Freudenberg (Abstr., 1893, ii, 506) has shown that trustworthy separations of metals may be obtained by arranging the pressure so that it exceeds the polarisation value of one metal and continues below that of the other. Working on this principle, separations of sodium from potassium, ammonium, caesium, rubidium, and lithium, of potassium from rubidium, caesium, and lithium, of caesium from rubidium, and of lithium from rubidium and caesium, have been successfully effected. The decomposition values of potassium and ammonium salts are so near to one another that these elements could not be separated.

It is suggested that this method of separation may prove useful in the estimation of small quantities of the alkali metals which occur in silicates.

E. G.

Volumetric Alkalimetric Method for Determining Alkaline Earths in Manures and Soils. Otto Foerster (Landw. Versuchs-Stat., 1908, 69, 235—243).—The substance (4—5 grams of quicklime or 8—10 grams of carbonate) is heated with N-hydrochloric acid (200—250 c.c.) in a 400 or 500 c.c. measuring flask for half an hour, then filled to the mark, and the whole filtered. A portion of the filtrate (100 c.c.), after adding the indicator, is treated with N/2 sodium hydroxide until the colour changes, then with 1—2 c.c. of N/2 acid, and boiled for a few minutes. When there is no, or only slight, precipitation of sesquioxides, the solution may be at once titrated back with N/2 alkali, and the number of c.c. used added to the number previously obtained. It is, however, usually advisable to dilute the cooled solution to 200 c.c. with water free from carbon dioxide and, after filtering, to titrate 100 c.c.

The approximate neutralisation of the acid solution is very desirable, as in this way most of the sesquioxides are separated. There must, however, always be an excess of acid so as to avoid the precipitation of calcium hydroxide.

It is pointed out that calcium silicates, owing to the readiness with which they are decomposed, are practically basic compounds. Calcium, in the form of hydrated silicate (or even after being ignited for half an hour), can be determined by the above method.

N. H. J. M.

Volhard's Copper Titration. Otto Kuhn (Chem. Zeit., 1908, 32, 1056—1057).—The author agrees with Theodor (this vol., ii, 898) that Volhard's process gives very satisfactory results. He has, however,
introduced a slight modification so as to avoid the harmful influence of free nitric acid, which has a solvent action on the copper thiocyanate precipitate.

The solution of the alloy in nitric acid is mixed with ammonia until a permanent precipitate has formed, which is then redissolved by adding a decided excess of sulphurous acid; the solution is then heated to boiling, and precipitated with ammonium thiocyanate, the excess of which is estimated in the filtrate with silver solution as usual. The nitric acid may, of course, be expelled completely by evaporating with sulphuric acid, but this would render the course somewhat more complicated.

**L. de K.**

**Volumetric Estimation of Mercury by means of the Thio-cyanate, Iodometric, and Acidimetric Processes.** Erwin Rupp (Chem. Zeit., 1908, 32, 1077—1079).—*Thiocyanate Process.*—The solution, which must contain the mercury as mercuric nitrate or sulphate and be absolutely free from mercurous nitrate, also from chlorine and nitrous acid, is titrated with \( N/10 \) ammonium thiocyanate, using 2 c.c. of 10% iron-alum solution as indicator; 1 c.c. of thiocyanate = 0.01 gram of mercury. When the solution has been prepared by dissolving mercury in nitric acid, the oxidation is conveniently completed with potassium permanganate, the excess of which is then removed with a pinch of ferrous sulphate.

**Iodometric Process.**—Twenty-five to fifty c.c. of the solution, containing about 0.1—0.25 gram of the salt, are mixed in a stoppered flask with 1—2 grams of potassium iodide, 10—20 c.c. of 10% potassium hydroxide are added, and then 3 c.c. of 40% formaldehyde diluted with 10 c.c. of water. After shaking for two minutes, 10 c.c. of glacial acetic acid are added, and then 25 c.c. of \( N/10 \) iodine. When all traces of metallic mercury have disappeared, the excess of iodine is titrated with \( N/10 \) thiosulphate; no indicator is wanted. One c.c. of iodine solution = 0.01 gram of mercury.

**Acidimetric Process.**—This is based on the strong affinity of mercury for cyanogen. The mercury should be present as chloride, which may be effected, if necessary, by addition of 1 gram of potassium chloride; any free acid is carefully neutralised with potassium hydroxide, using phenolphthalein as indicator, and 20 c.c. of \( N/2 \) potassium cyanide are added. The excess of cyanide is then titrated with \( N/2 \) hydrochloric acid, using methyl-orange as indicator; 2 mols of cyanide = 1 at. of mercury. The titration may also be performed by simply adding the cyanide solution until the liquid turns pink.

Notwithstanding the great stability of the cyanide, it is completely decomposed by potassium iodide with formation of potassium cyanide, which may then be titrated with \( N/2 \) hydrochloric acid. Mercuric oxide may also be titrated with acid in presence of potassium iodide, from which it liberates the hydroxide. Instead of standardising the cyanide with \( N/2 \) acid, it may be also checked against a solution of mercuric chloride of known strength.

**L. de K.**

**Volumetric Estimation of Mercuric Oxide.** Erwin Rupp and W. F. Schirmer (Pharm. Zeit., 1908, 53, 928).—Mercuric oxide
cannot be estimated by dissolving in hydrochloric acid and titrating the excess of this with alkali; but it may be titrated by dissolving about 0.25 gram in 10—20 c.c. of water containing 2—3 grams of potassium iodide, and titrating with N/10 hydrochloric acid, using methyl-orange as indicator. Heating on the water-bath promotes the solution of the oxide.

Another plan is to boil 0.25 gram of the oxide with 50 c.c. of water and 2 grams of mercuric cyanide. When all is dissolved, 1 gram of salt is added, and when cold the solution is titrated with N/10 hydrochloric acid, using methyl-orange as indicator.

The process may be employed for the testing of ointments. Two grams of the sample are boiled with 2 grams of mercuric cyanide and 50 c.c. of water until all the oxide has dissolved, 1 gram of salt is added, and the solution titrated with N/10 acid. On account of a slight saponification taking place, owing to the liberation of potassium hydroxide, the potassium iodide process is unsuitable for the testing of fatty ointments.

L. de K.

Estimation of Manganese by means of Potassium Ferrocyanide. Hermann Bollenbach and E. Luchmann (Chem. Zeit., 1908, 32, 1101—1102, 1114—1115).—The solution, which must be free from metals precipitable by hydrogen sulphide, and also from ferrous iron, cobalt, nickel, chromium, and reducing substances, is mixed with an excess of potassium ferricyanide. A decided excess of aqueous sodium hydroxide is added, and the manganese dioxide is collected and washed with hot water. The filtrate is acidified with excess of dilute sulphuric acid, and the potassium ferrocyanide formed in the reaction titrated with permanganate as usual. Two mols. of ferrocyanide = 1 at. of permanganate.

In presence of ferrous iron, an aliquot part of the solution should be titrated with permanganate, and an allowance should be made.

L. de K.

New Method of Attacking Ferro-compounds, particularly Ferro-silicon. Paul Nicolardot (Compt. rend., 1908, 147, 676—678).—In decomposing ferro-silicon by chlorine at a red heat, it is impossible to retain all the silicon chloride. The author finds that ferro-silicon is completely decomposed by heating with commercial sulphur chloride at 70° for three minutes. Ferro-titanium is somewhat less easily decomposed, whilst ferro-chromium requires a temperature above 120°. The process is carried out in a 250 c.c. flask, closed by a small graduated dropping funnel of special shape. The apparatus is evacuated, and exactly 2 c.c. of sulphur chloride cautiously introduced. On completion of the action which is started by heating, a few drops of ammonia solution are introduced, and the flask is filled up with water as it gradually cools. The products are estimated in the usual way.

R. J. C.

Separation of Tungstic Acid from Silica. Paul Nicolardot (Compt. rend., 1908, 147, 795—797).—This separation is most readily effected by heating the mixture at 500° in a current of air charged
with chloroform vapour, which, unlike carbon tetrachloride, does not give a deposit of carbon at this temperature. The tungsten is thus removed as a mixture of oxychlorides.

W. O. W.

Reduction of Stannic Oxide. DAVID B. DOTT (Pharm. J., 1908, 81, 585).—When stannic oxide (0.15 gram) is heated with hypophosphorous acid (0.5 gram) over a Bunsen flame during thirty minutes, it is converted into stannous phosphate or pyrophosphate, which is readily soluble in warm hydrochloric acid. Silica remains unaffected by this treatment, and, if present, can be filtered from the hydrochloric acid solution of the tin.

T. A. H.

Physico-chemical Analysis of Mineral Water. ERNST HINTZ and LEO GRÜNHUT (Zeitsch. angew. Chem., 1908, 21, 2359—2368. Compare ibid., 1903, 16, 842).—A mathematical paper comprising a reply to Roloff’s criticism of the formula used by the authors for calculating the middle dissociation value from the specific conductivity. The formulae used by Roloff are deduced and shown to be only applicable in special cases, and a complete derivation of the authors’ formula is given for the first time. Roloff’s assumptions respecting the calculation of the freezing point are discussed, and examples given showing an error of +5.8% from the observed values when use is made of his mode of calculation.

J. V. E.

Assay of Turpentine and Estimation of Mineral Oil in Rosin Spirit. R. ADAN (Bull. Soc. chim. Belg., 1908, 22, 389—396).—Herzfeld’s sulphuric acid process is quite untrustworthy for the detection of petroleum products in turpentine or rosin spirit, but Burton’s nitric acid method gives satisfactory results provided the temperature is lowered to —10°. Some samples, although pure, may still give 1—2% of insoluble oils.

Petroleum in turpentine or rosin spirit may also be detected by collecting the distillate passing over between 120—150°. In the absence of petroleum, the fraction is miscible in all proportions with aniline or acetic anhydride.

Pure turpentine should practically distil over at 162°. In the case of rosin spirit, the bulk of the distillate collects between 165—175°, and the distillation is not quite finished even at 180°. This fact facilitates its detection in mixtures. It may be also identified by Grimaldi’s test with tin and hydrochloric acid, which gives a green coloration, and also by its odour.

L. DE K.

Estimation of Essential Oils in Spices. R. REICH (Zeitsch. Nahr. Genussm., 1908, 16, 497—509).—The method described by Mann (Abstr., 1902, ii, 432) gives trustworthy results if the point at which the solvent has been removed completely can be exactly determined, and for this purpose the author recommends the following modification as giving the best result. The solution of the ethereal oil in ether, or pentane, is placed in the evaporation flask, and the solvent is evaporated almost completely. A few drops of isopropyl
chloride are then added to the flask, and the drying is continued until the current of air and other gases issuing from the platinum jet no longer gives a green flame when allowed to impinge against a heated copper gauze. The method is trustworthy for estimations of essential oils of cinnamon, cassia, cloves, peppermint, anised, thyme, ginger, and camphor, but cannot be used in the case of oils of caraway, lemon, eucalyptus, and turpentine, as these contain extremely volatile substances.

W. P. S.

Detection of Small Quantities of Methyl Alcohol in the Presence of Ethyl Alcohol. LEONHARDT E. HINKEL (Analyst, 1908, 33, 417—419).—The following method, in which the alcohols are oxidised to their corresponding aldehydes, and the formaldehyde then detected by means of morphine hydrochloride, is stated to be capable of detecting the presence of methyl alcohol in ethyl alcohol when the proportion of the former alcohol is not less than 5%. One c.c. of the mixed alcohols is placed in a small distilling flask, and the oxidising agent is added. If ammonium persulphate is used, 0·8 gram of the salt is added, followed by 3 c.c. of dilute sulphuric acid (1:5); or in the case of potassium dichromate, 1·5 grams of the salt and 1·5 grams of pure sulphuric acid are employed. In both cases, the mixture is diluted with water to 20 c.c. and distilled, the distillate being collected in test-tubes in five separate portions of 2 c.c. each. The first two portions, which will contain all the acetaldehyde, are rejected; to each of the remaining portions are added a few drops of 0·5% morphine hydrochloride solution, and concentrated sulphuric acid is run into each tube so as to form a layer at the bottom. In the presence of formaldehyde (resulting from the oxidation of the methyl alcohol), a violet ring will be formed at the junction of the two liquids. Pure ethyl alcohol always yields a trace of formaldehyde on oxidation, but the reaction obtained when 5% of methyl alcohol is present cannot be confused with the coloration due to the ethyl alcohol.

W. P. S.

Apparatus for Polarising at 87°. ALBERT P. SY (J. Amer. Chem. Soc., 1908, 30, 1790—1791).—Apparatus is described for determining the rotatory power of sugar solutions at 87°. It consists essentially of a jacketed polariscope tube heated by means of a current of water from an instantaneous water heater. For details, the description and diagram in the original must be consulted.

E. G.

Influence of Clarification with Lead Acetate on the Estimation of Invert Sugar. O. SCHREFFELD (Zeitsch. Ver. deut. Zuckerind, 1908, 634, 947—956).—It has been shown by Prinsen-Geerligs (this vol., ii, 991) and others that, under certain conditions, levulose and, in less degree, dextrose are partly precipitated from their aqueous solutions by basic lead acetate. The author has carried out experiments to ascertain whether the use of this reagent for clarifying solutions of commercial sugar products interferes with the estimation of invert sugar by the reduction of Fehling's solution.
The results show that the reducing power of invert sugar may be lowered by basic lead acetate, this being especially the case with low products and with high contents of invert sugar. When neutral lead acetate is employed, there is, however, little danger of low results being obtained.

T. H. P.

Optically Active Non-saccharine Substances in Sugar Beet which are Eliminated by the Action of Lime in the Purification of the Sap, and their Polarimetric Estimation. FRANZ HERLES (Zeitsch. Zuckerind. Böhm., 1908, 33, 94—98).—Polarimetric determinations in beet juice before and after boiling with lime generally resulted in lower figures after treatment with lime. The differences varied between 0·0% and 0·4%. Beet juice therefore contains, as a rule, some optically active non-sugar which is either precipitated or destroyed by the lime employed during the process of purification.

N. H. J. M.

Colour Reactions of the Carbohydrates Based on the Formation of Furfuraldehyde from them. Reactions with Indole and Carbazole. C. FLEIG (J. Pharm. Chim., 1908, [vi], 28, 385—392).—When 0·5 c.c. of a dilute solution of sucrose or other carbohydrate (many proteins also react) is treated with 3—4 c.c. of pure hydrochloric acid, the mixture boiled momentarily (if any coloration is thereby produced the carbohydrate solution should be diluted and less of it used), and 3—4 drops of a 0·1% alcoholic solution of indole added, a yellow-orange or reddish-orange coloration is produced. One to two drops of a 0·01% solution of sucrose diluted to 0·5 c.c. will give this reaction. Most of the sugars, starches, dextrins, glucosides, etc., react, but the polybasic alcohols, sorbitol, dulcitol, etc., are inactive. If sulphuric acid is used in place of hydrochloric acid, a blank experiment containing no carbohydrate must be made for comparison. The reaction with carbazole (which is given by the same substances as give the indole reaction) is obtained by adding 1—2 drops of a saturated alcoholic solution of carbazole and 1 c.c. of pure sulphuric acid to 0·5 c.c. of the carbohydrate solution, when a reddish-violet ring is formed at the junction of the two liquids. A blank experiment is necessary also in this case, since at certain temperatures carbazole and sulphuric acid react, giving red or violet colorations.

E. H.

Polarimetric Estimation of Starch. CARL J. LINTNER (Zeitsch. Nahr. Genussm., 1908, 16, 509—512).—Sulphuric acid may be used in place of hydrochloric acid in the method described previously by the author (Abstr., 1907, ii, 823). 2·5 Grams of the finely-ground flour are mixed in a mortar with 10 c.c. of water and 20 c.c. of sulphuric acid, D 1·7 (77%); at the end of twenty-five minutes the mass is washed into a 100 c.c. flask by the aid of dilute sulphuric acid (1 : 3), 5 c.c. of 8% phosphotungstic acid solution are added, and the process then continued as described (loc. cit.). When sulphuric acid is used, barley starch has $[\alpha]_D^0 191·7^\circ$, and this value differs for each kind of starch. Unless the value be determined for each starch, the hydrochloric acid method is to be preferred, as, in this case, the value is fairly constant.

W. P. S.
Estimation of Tartaric Acid in Wines by Evaporation. W. Mestrezat (Ann. Chim. anal., 1908, 13, 433—436).—The evaporation method proposed by Pasteur and modified by Reboul is considered to be more trustworthy than the official (French) method for the estimation of tartaric acid in wines. The following way of carrying out the estimation is recommended: 50 c.c. of the wine are evaporated to such an extent that the residue, when cold, is semi-fluid. After the lapse of five days, the crystals of potassium hydrogen tartrate which have formed are washed with 40% alcohol saturated previously with potassium hydrogen tartrate, and are then titrated in the usual manner.

W. P. S.

Estimation of Malic Acid. M. Emmanuel Pozzi-Escot (Bull. Assoc. chim. Sucri. Dist., 1908, 26, 266—267*).—It is pointed out by the author that the untrustworthiness of both the American official method and the process described by Cowles (Abstr., 1908, ii, 904) for the estimation of malic acid is mainly due to the use of precipitants which are insoluble in alcohol, and that, at the same time, calcium malate is appreciably soluble in 85% alcohol. Malic acid is best precipitated by means of a solution of barium bromide in 96% alcohol, the solution being rendered slightly ammoniacal before use, and the precipitation made in the presence of an excess of alcohol.

W. P. S.

Detection of Benzoic Acid in Butter. Lucien Robin (Ann. Chim. anal., 1908, 13, 431—433).—The author modifies the method described by Halphen (Abstr., 1908, ii, 906) in order to prevent the formation of an emulsion when the butter is extracted. A portion of the butter is melted together with 50 c.c. of water, 15 c.c. of alcohol, and 0.5 gram of sodium hydrogen carbonate; the aqueous portion is then separated, acidified with sulphuric acid, heated, and filtered. The filtrate is shaken with ether, and the ethereal extract, after being washed with a mixture of 20 c.c. of water and 5 c.c. of alcohol, is shaken with 25 c.c. of the same water-alcohol mixture to which has been added 0.3 gram of sodium hydrogen carbonate. The aqueous portion, containing the benzoic acid as its sodium salt, is separated and evaporated to dryness; the residue is heated with 5 c.c. of sulphuric acid and 10 drops of fuming nitric acid until sulphuric acid fumes are given off, and the solution is then poured into 50 c.c. of cold water. After rendering the solution ammoniacal, a few drops of ammonium sulphide are added, when an orange-red coloration develops rapidly if the butter contains benzoic acid.

W. P. S.

Colour Reactions of Aromatic Aldehydes with Phenols and Various Cyclic, Heterocyclic, and Open-chain Compounds. C. Fleig (Bull. Soc. chim., 1908, [iv], 3, 1038—1045).—When an acid is added to a solution of an aromatic aldehyde in alcohol also containing one of a variety of substances of which the following may be mentioned as types, phenol, gallic acid, camphor, menthol, aniline, pyrrole, indole, mercaptan, and isobutyl alcohol, a coloration, usually yellow, orange, red, or violet, or in some cases a

* and Bull. Soc. chim. Belg., 1908, 22, 413—414.
play of colours, is produced. The acid used may be sulphuric, hydrochloric, lactic, or a mixture of the last two. The colours given by menthol and terpin are similar to those yielded by cholesterols and biliary acids.

The aminophenols yield orange-red colorations, which turn yellow and finally disappear on addition of excess of acid. With alkalis they also change to yellow, but on the further addition of acid in excess become red. These changes are explained by assuming the existence in the solution of a tautomeric substance $d$; this, on addition of sodium hydroxide, forms a product $\text{Na}d$, which is yellow in presence of excess of alkali and red in presence of excess of acid.

These colour reactions can be applied in the detection of free hydrochloric acid in gastric juice, and possibly to the detection of mineral acids in adulterated wines.

**Colorimetric Estimation of Benzaldehyde in Almond Extracts.** **Alpheus G. Woodman** and **E. F. Lyford** (*J. Amer. Chem. Soc.*, 1908, 30, 1607—1611).—The reagents required are magenta decolorised by sulphurous acid and alcohol free from aldehyde. The former is prepared by dissolving 0·5 gram of magenta in 100 c.c. of water, and adding a solution containing 20 grams of sulphur dioxide. When decolorised, the solution is diluted to one litre. The alcohol is purified by distilling over silver oxide. To the distillate are added 25 grams of $m$-phenylenediamine hydrochloride per litre, a rapid current of air is drawn through the solution for three hours, and the alcohol is again distilled, the first 100 c.c. being rejected. The method as used with commercial almond extract may be outlined as follows:

Ten grams of the sample are diluted to 50 c.c. with the purified alcohol. Of this, 2 c.c. are placed in a Hehner cylinder and diluted with alcohol to 20 c.c. Three standard solutions are made up by diluting 2, 4, and 6 c.c. of benzaldehyde solution (alcohol containing 1 mg. of benzaldehyde per c.c.) to 20 c.c. and placing them in similar colorimeter tubes. The tubes are then placed for some time in water at 15°, and to the contents of each are added rapidly 20 c.c. of the magenta reagent, also at 15°. After ten minutes, the unknown sample is matched with the nearest standard in the usual manner by withdrawing part of either liquid. The depth of colour is proportional to the amount of benzaldehyde present.

**Detection of “Saccharin” ($o$-Benzoisulphinide) and other Artificial Sweetening Materials in Beverages and Foods.** **Alberto Bianchi** and **Ettore Di Nola** (*Boll. chim. farm.*, 1908, 47, 599—605. Compare this vol., ii, 440).—The authors give the following modification of the method devised by Villiers and others (compare Abstr., 1904, ii, 599) for the detection of $o$-benzoisulphinide in foods. The liquid, or, in the case of a solid, a suitable liquid extract, is freed from alcohol, heated to boiling, and acidified with about 20 drops of acetic acid per 100 c.c. The liquid is shaken, cooled, and mixed with about 10 c.c. of 20% lead acetate solution per 100 c.c. After half an hour, the excess of lead is precipitated by means of a solution containing 10% of sodium sulphate and 10% of
sodium phosphate, double the volume of lead acetate used being always sufficient. The filtered liquid, concentrated to 70—80 c.c. if necessary, is acidified with 6—8 c.c. of dilute sulphuric acid (1:3), and shaken in a separating funnel with its own volume of a mixture of equal parts of ether and benzene. The benzene-etheral extract is then slowly evaporated in a flat-bottomed glass dish. The residue is tested for (1) o-benzoicsulphinide by tasting, and by fusion with sodium hydroxide at 270°; (2) salicylic acid by extracting with a small quantity of alcohol, diluting the alcoholic solution, and adding ferric chloride. If salicylic acid is found, it must be destroyed before the residue is tested for o-benzoicsulphinide (compare Villiers, etc., Abstr., 1904, ii, 599).

The above method also serves for the detection of the ammonium ("sucramine"), sodium ("sucrose"), and magnesium derivatives of o-benzoicsulphinide, and of the so-called extract of sugar-cane, which is a solution of o-benzoicsulphinide in glycerol.

"Dulcine" or "sucrel" (p-phenetolcarbamide) may be detected by treating a small portion of the residue left by the benzene-etheral extract (above) with silver nitrate (compare Ruggeri, Ann. Lab. Centr. Gabelle, 3, 143).

T. H. P.

Microchemical Studies. A. Bolland (Monatsh., 1908, 29, 965—994).—A paper dealing with the microchemical detection of the following substances: methylamine, dimethylamine, trimethylamine, ethylamine, diethylamine, triethylamine, propylamine, amylamine, hexylamine, neurine, ethylenediamine, pentamethylenediamine, choline, betaine, methylguanidine, α-aminovaleric acid, parvoline, pilocarpine, piperine, conine, conhydrine, ψ-conhydrine, hyoscine, cornutine, ergotinine, colchicine, emetine, lobelline, solanine, solanidine, chelidonine, chelerythrine, sanguinarine, strophanthin, digitalin, picrotoxin, and santonin. The appearance, crystallographic and optical properties of the precipitates obtained on treating the tartrates of these substances with various reagents are described.

The refractive indices of the following alkaloids, determined by the immersion method, are given: solanine, solanidine, colchicine, conhydrine, ψ-conhydrine, and ergotinine; also of the tartrates of morphine, thebaine, quinine, cinchonidine, coniine, nicotine, hydastine and cocaine.

W. H. G.

Colour Reactions of Proteins. C. Fleig (Ann. Chim. anal., 1908, 13, 427—431).—The following colour reactions are given by the proteins which contain a carbohydrate group in their molecule, namely, ovalbumin, ovoglobulin, serum-albumin, and particularly the glucoproteins (mucin). The test is best carried out by mixing a few drops of a 20% solution of the reagent with a dilute solution of the protein and pouring the mixture on to the surface of a little concentrated sulphuric acid contained in a test-tube. Orcinol, catechol, pyrogallol, phenol, menthol, camphor, terpene, carbazole, thiophen, and pyrrole give red colorations; resorcinol and indole blue, and phloroglucinol, reddish-brown.

Morgan, Gilbert Thomas, and (Miss) Frances Mary Gore Micklethwait, derivatives of para-diazoimino-benzene, T„ 602 ; P„ 48 ; discussion, P„ 49.

a study of the diazo-reaction in the diphenyl series, T„ 614 ; P„ 51.

organic derivatives of arsenic. Part I. Dicamphorylarsenic acid, T„ 2144 ; P„ 283 ; discussion, P„ 269.

Morgan, John Livingston Rutgers, and Eric Higgins, weight of a falling drop and the laws of Tate; determination of molecular weights and critical temperatures of liquids by the aid of drop weights, A„ ii, 688.

Morgan, John Livingston Rutgers, and John E. McWhorter, estimation of carbon monoxide in atmospheric air, A„ ii, 66.

Morgan, John Livingston Rutgers, and Reston Stevenson, weight of a falling drop and Tate’s laws; determination of the molecular weights and critical temperatures of liquids by the aid of drop weights, A„ ii, 356.

Morgan, Will J. See William Jay Karslake.

Morgenroth, Julius, and R. Kaya, the action of cobra venom in destroying complement, A„ ii, 313.

Morgenstern, Otto. See Moritz Kohn.

Morozewicz, Józef A„ composition of nepheline, A„ ii, 201.

Morse, Fred. W„ effect of temperature on the respiration of apples, A„ ii, 616.

Morse, H. V. See Harmon Northrop Morse.
INDEX OF AUTHORS.

Morse, Harmon Northrop, and William West Holland, osmotic pressure of dextrose solutions at 10°, A., ii, 759.

Morse, Harmon Northrop, and B. F. Lovelace, improved manometers for measurement of osmotic pressure, A., ii, 1020.

Morse, Harmon Northrop, and B. Mears, osmotic pressure of sucrose solutions at 15°, A., ii, 1019.

improvement in cells for the measurement of osmotic pressure, A., ii, 1019.

Morse, Harmon Northrop, and H. V. Morse, osmotic pressure of sucrose solutions at 10°, A., ii, 671.

Moruzzi, G., the quantitative recovery of choline from lecithin, A., i, 395.

Moss, H. See Samuel Walter Johnson Smith.

Mosler, Gustav, fission of hydrogen cyanide from amides of α-bromo-fatty acids accompanied by the formation of an aldehyde or ketone, A., i, 133.

decomposition of chloroform by alcoholsic alkali hydroxides, A., i, 750.

decomposition of trichloroisopropyl alcohol by aqueous or alcoholsic alkali hydroxides, A., i, 751.

Mott, William R. See Harrison Eastman Patten.

Motylewski, Sigmund, 3-hydroxy-1,2-dihydroquinoxaline and its derivatives, A., i, 370.

Moulin, M., ionisation of gases by α-rays, and the hypothesis of initial recombination of the ions, A., ii, 921.

Mouriel, José Rodríguez, changes in the colour of calcium sulphide under the influence of light, A., ii, 140.

Moureu, Charles, and Robert Biguard, rare gases of thermal waters; gaseous outputs of some springs, A., ii, 277.

Moureu, Charles, and Amand Valeur, sparteine; application of Hofmann's reaction to sparteine; methylhemisparteine, A., i, 43.

two isomeric methylsparteines, A., i, 44.

sparteine; isomerisation of α-methylsparteine, A., i, 103.

isosparteine, an isomeride of sparteine, A., i, 206.

sparteine, XII., A., i, 563.

Moussu, and Goupil, action of chlorine in the tubercle bacillus, A., ii, 123.

Mouton, Henri. See A. Cotton.

Możdżoński, Leo von. See Félix Benjamin Ahrens.

change of state in quartz at 570°, A., ii, 302.

Müller, Arthur, preparation of hydrosols of metallic hydroxides from hydrogels, A., ii, 286.

Müller, Erich, (Berlin). See Walter Cronheim.

Müller, Erich, (Stuttgart), explanation of supertension, A., ii, 802.

Müller, Erich, and Friedrich Kapeller, the reducing and oxidising power of salts of iron, A., ii, 192.

Müller, Ernst, ψ-diazoeetic acid, A., i, 922.

Müller, Ernst. See also Theodor Curtius.

Müller, Eugen, gas-generating apparatus for analytical purposes, A., ii, 129.

Müller, F. See Heinrich Ley.

Müller, Fritz. See Richard Willstätter.

Müller, Gustav, circulation burette, A., ii, 626.

new burette clamp, A., ii, 1069.

Müller, Gustav, and O. Berchem, automatic safety burette, A., ii, 775.

Müller, Johannes, the utilisation of sugar during muscular activity, A., ii, 713.

Müller, K. See Michael I. Konowaloff.

Müller, Max, [nutritive value of non-proteins in hay], A., ii, 726.

Müller, Noé L. See Rudolf Wegscheider.

Müller, O. See Julius Tröger.

Müllermeister, Wilhelm, the absorption spectra of chlorophyll and its derivatives, A., i, 197.

Münther, F. See Wilhelm Schneidewind.

Müntz, Achilles, and Auguste Trillat, origin and variations of sulphates in beer; interpretation of analytical results, A., ii, 782.

Münziger, A. See Paul Wagner.

Muir, Matthew Moncrieff Pattison, volumetric estimation of iron in ferric compounds, A., ii, 228.

Müller, Joseph Auguste, acid energy of thiosulphuric acid and the decomposition of this acid, A., ii, 102.

deduction of Gibbs' phase rule, A., ii, 466.

Müller, Paul Thiébaud, and H. Armandet, alkali electrode, A., ii, 146.
INDEX OF AUTHORS.

Muller, Paul Thibaud. See also Albin Haller.
Müller, Paul. See Walther Löb.
Mumm, Olo, kinetics of ethyl diazoacetate and the dilution law, A., ii, 469.
Mummery, John Percy Lockhart, and William Leggo Symes, duration of effect of pituitary extract on blood pressure, A., ii, 767.
Muñoz del Castillo, José, radioactivity of water from Castromonte and Puertollano, A., ii, 550. coefficient of absorption of radioactive emanations in different liquids, A., ii, 749.
radioactivity of the waters of Lerez, A., ii, 750.
radioactivity of water from Cucho, A., ii, 750.
extraordinary radioactivity of water from a spring at Valdermorillo, A., ii, 1004.
radioactivity of three springs at Oña (Burgos), A., ii, 1004.
Muñoz del Castillo, José, and Faustino Díaz de Rada, photographic impressions produced by radium emanation, A., ii, 749.
Munroe, Charles Edward, artificial hematite crystals, A., i, 116.
Muraour, Henri, constant head of water for laboratories, A., ii, 479.
Muraro, F., solubility of true and false tannates of quinine, A., i, 451, 1004.
Murphy, Arthur, jun. See Arthur Michael.
Murschhauser, Hans. See Wilhelm Prandtl.
Musselius, R., crystalline polymeride of isoubutilsol, A., i, 761.
Muyneck, R. de, conductivity of gaseous mixtures at the moment of explosion, A., ii, 345.

N.
Nabokich, A. J., the liberation of carbon dioxide by dead parts of plants, A., ii, 616.
Nacken, Richard, langbeinite and vanthoffite [K2SO4, 2MgSO4, and 3Na2SO4, MgSO4], A., i, 692.
Nádai, Géza, See Fritz Ullmann.
Nakamura, M., the most favourable ratio of lime to magnesia for the mulberry tree, A., ii, 126.
Namba, I., behaviour of onions to stimulants, A., ii, 618.
Namba, I., and C. Kanomata, efficacy of calcium cyanamide under different manuring conditions, A., ii, 623.
Nametkin, S. S., action of nitric acid on saturated hydrocarbons, A., i, 829.
Namias, Rodolfo, analyses of some alloys and slags, A., ii, 326.
Naquin, W. P. See Fritz Zerban.
Narbutt, J. von. See Karl A. Hofmann.
Nasini, Raffaeo, origin of the boric acid in the Soffioni of Tuscany, A., ii, 862.
ozonisation of air by the action of radium salts and emanation, A., ii, 793.
Nawiasky, Paul, the decomposition of amino-acids by Bacillus proteus vulgaris, A., ii, 614.
old and new nitrogenous fertilisers; calcium cyanamide, calcium nitrate, ammonia sulphate, and sodium nitrate, A., ii, 1068.
Nef, John Utric, dissociation processes in the sugar group. I. Behaviour of carbohydrates towards Fehling's solution and other oxidising agents, A., i, 5.
Negro, C. See G. Costanzo.
Neilson, Charles Hugh, and Oliver P. Terry, effect of potassium iodide on ptyalin, A., ii, 612.
Nelken, F., and Hugo Simonis, action of Grignard compounds on o-phthalaldehyde, A., i, 348.
Nelson, John Maurice. See Kaufman George Falk.
Nelson, Louis, the composition of the protamine from salmon spermatozoas, A., i, 1030.
thyamine, a protamine from the thymus gland, A., i, 1030.
Neminsky, W. W., and Wladimir A. Plotnikoff, electrolysis of the compounds of aluminium bromide with toluene and benzene, A., i, 407.
Neogi, Purnâchandra, reduction of Fehling's solution to metallic copper; decomposition of copper mirrors on glass, A., ii, 848.
Neovius, W. See Roland Scholl.

INDEX OF AUTHORS.

Osborne, E. I., conversion of methyl alcohol into formaldehyde and the preparation of formalin, A., i, 77, 761.

constitution of sodium hyposulphite and formaldehydesulphoxylate, A., i, 132.

oxidation of ethyl, propyl, isobutyl, and anyl alcohols by a contact process, A., i, 306.

contact oxidation of hydrocarbons, A., i, 520.

contact oxidation of hydrocarbons, A., i, 753.

method of obtaining resins from turpentine and the preparation from them of lac, varnishes, &c., A., i, 815.

constitution of sodium hyposulphite, A., ii, 181.

contact oxidation of ammonia and organic bases, A., ii, 582.

detection of ruthenium in platinum alloys, A., ii, 231.

estimation of sulphur in iron and steel, A., ii, 731.

estimation of manganese in iron and manganese ores, A., ii, 898.

Orton, Kennedy Joseph Previté, and Reginald William Everatt, the reaction of diazonium salts with mono- and di-hydric phenols and with naphthols, T., 1010; P., 118.

Orton, Kennedy Joseph Previté, and (Miss) Constance Pearson, the wandering of bromine in the transformation of nitroaminobromobenzences, T., 725; P., 62.

Orton, Kennedy Joseph Previté, and (Miss) Alice Emily Smith.

Ōsaka, Yūkichī, inversion of sucrose, A., i, 856.

Osborne, R. W. See Isaac King Phelps.

Osborne, Thomas Burr, and Samuel Hopkins Clapp, hydrolysis of the globulin from the almond (amandin); hydrolysis of the proteins of maize; hydrolysis of gladin from rye, A., i, 115.

Osborne, Thomas Burr, and Frederick W. Heyl, pyrimidine derivatives in nucleic acid, A., i, 376.

hydrolysis of vigin, A., i, 744.

hydrolysis of legumin from the vetch, A., i, 843.

hydrolysis of legumenin from the pea (Pisum sativum), A., i, 928.

Osborne, Thomas Burr, and Frederick W. Heyl, hydrolysis of vicillin from the pea (Pisum sativum), A., i, 929.

hydrolysis of chicken flesh, A., ii, 967.

hydrolysis of fish muscle, A., ii, 1055.

Ost, Hermann, and F. Klein, formic acid in glacial acetic acid, A., ii, 903.

Osthelder, F. See Hermann von Tappeiner.

oxidation of aniline by halogen acids, A., i, 373.

explanation of the formation of indoline, A., i, 373.

Ostromification, Iwan von, action of dichloroacetic acid on aniline and its homologues. I. and II., A., i, 82, 888.

products of the nitration of o-chloro-nitrobenzene, A., i, 867.

structure of benzene. I. Polymorphic modifications of aromatic compounds. II. Homogeneity of the ortho- and of the meta-derivatives of benzene. III. The two chemically isomeric 2:4-dinitrophenols, A., i, 868.

action of glyoxylic acid and of diacetylglyoxylic acid on aniline and its homologues, A., i, 889.

optical isomerides, A., ii, 913.

Ostwald, Wolfgang, influence of electrolytes on the coagulation-temperature of egg-albumin, A., i, 375.

nature of the combination of gases in blood and its constituents; preliminary notice, A., ii, 509.

system of colloids, A., ii, 820.

Ostwald, Wolfgang, and Friedrich Goppeisroeder, time-law of the capillary rise of liquids and the relationship of velocity to the chemical constitution, A., ii, 203.

Ott, E. See Hermann Staudinger.

Ott, K. See Karl A. Hofmann.

Otto, Andreas, detection of dextrose in urine, A., ii, 739.

Owen, Gwilym, and A. Ll. Hughes, molecular aggregations produced in gases by sudden cooling, A., ii, 565.

P.

Paal, Carl, and Leo van Gember, sec.-aminoacetals, A., i, 511.
Palladin, Wladimir N., rôle of the reductase in alcoholic fermentation, A., i, 589.

the respiratory pigments of plants, A., ii, 416.

Palmer, Howard E. See Philip Embury Browning and Isaac King Phelps.

Pander, Robert. See August Michaelis.

Pannain, Ernesto, certain alloys of silver, A., ii, 495.

rapid analysis of copper-plating baths, A., ii, 537.

Panzer, Theodor, doubly-refracting substances from pathological organs, A., ii, 122.

detection of vegetable poisons in decomposed animal bodies, A., ii, 997.

Pappadà, Nicola, electrical nature of colloidal solutions, A., ii, 1024.

Pari, Giulio Andrea, the influence of nitrogen-free sources of energy on the rate of protein decomposition by the organism, A., ii, 961.

the influence of the thyroid gland on the rate of decomposition, A., ii, 962.

Paris, Giulio, lactic acid in wine, A., ii, 543.

Pariselle. See Robert Lespieau.

Parker, L. E. L. See Marcus Seymour Pembrey.

Parow, Edmund, and Franz Neumann, evaluation of commercial starch, A., ii, 543.

Parr, Samuel Wilson, Parr's method of estimating the heat of combustion of coal, A., ii, 533.

sodium peroxide in certain quantitative processes, A., ii, 628.

Parravano, Nicola, and Aldo Mieli, acid phosphates, A., ii, 837.

Parravano, Nicola, and A. Pasta, chromatates, A., ii, 294.

Parrozzani, A. See Francesco Scurti.

Parsons, (the Hon.) Charles Algermon, and Alan Archibald Campbell Swinton, conversion of diamond into coke in high vacuum by cathode rays, A., ii, 275.

Parsons, Charles Lathrop, solution in a dissolved solid, A., ii, 58.

Parthell, Alfred, red lead and their examination, A., ii, 69, 227.
INDEX OF AUTHORS.

Pascal, P., some complex iron salts in which the iron is masked, A., ii, 193.

Patterson, Thomas Stewart, and Andrew McMillan, the polarimetric study of intramolecular rearrangement in inactive substances, T., 1041; P., 135.

- a new method for studying intramolecular change, A., ii, 206.

Patterson, Thomas Stewart, and David Thomson, the influence of solvents on the rotation of optically active compounds. Part XI. Ethyl tartrate in aliphatic halogen derivatives, T., 355.

Pauli, E. See Karl Badeker.

Pauli, Wolfgang, and Hans Handovsky, changes in the physical state of colloids. VI. Compounds of salt ions with amphoter protein, A., i, 707.

Pauly, Hermann, preparation of the cyclic carbonate of protocatechic acid, A., i, 423.

Payv, Frederick William, and Hubert W. Bywaters, formation of glycojen by yeast, A., ii, 56.

Pawek, Heinrich, preparation of radium from pitchblende, A., ii, 917.

Pawlewski, Bronislaw von, characteristic reaction of anthranilic acid, A., i, 638.

Pawloff, P. N., relation of melting point to the surface of the granules of a solid substance, A., ii, 927.

Pearce, J. N. See Harry Clary Jones.

Pearson, (Miss) Constance. See Kennedy Joseph Preville Orton.

Pedersen, P. O., surface tension of liquids investigated by the method of jet vibration, A., ii, 158.

Pedrina, S. See Giovanni Pellini.

Pélabon, Henri, compounds formed by silver selenide with the selenides of arsenic, antimony, and bismuth, A., ii, 587.

tellurides of arsenic and bismuth; cryoscopic constant of tellurium, A., ii, 687.

Pelecani, Luciano, the zeolites of Montresta (Sardinia), A., ii, 864.

Pelet-Jolivet, Louis, dissociation by adsorbing substances of the compounds formed by basic and acidic dyes, A., ii, 18.

Pelet-Jolivet, Louis, and N. Andersen, influence of acids and bases on the absorption of acidic and basic dyes by wool, A., ii, 59.
Pelet-Jolivet, Louis, and N. Andersen, fixation of different derivatives of the same colouring matter and explanation of dyeing, A., ii, 1026.

Pelet-Jolivet, Louis, and V. Garuti, iodometric estimation of basic colours, A., ii, 441.

volumetric estimation of dyes, A., ii, 441.

Pelli, Arrigo. See Ciro Ravenna.

Pellacani, Paul, and Folli, so-called antitoxic power of animal tissues towards strychnine, A., ii, 1062.

Pellegrino, M. See Giuseppe Kernot.

Pellet, Henri [Jean Baptiste], normal tubes for saccharimeters, A., i, 235.

Pellizzari, Guido, and Angelo Repetto, action of cyanogen bromide on hydrazine; N-aminoguanazoloe (guanazline). III., A., i, 65.

Pelloux, A., mineralogy of Sardinia. II., A., ii, 863.

Pelly, Russell George. See Ernest Goulding.

Peltner, Erich. See Richard Wolfenstein.

Peltrisot, detection of rice starch in wheat flour, A., ii, 236.

Pember, F. R. See Burt Laxes Hartwell.

Pembrey, Marcus Seymour, Cheyne-Stokes respiration, A., ii, 204.

Pembrey, Marcus Seymour, and E. Cook, influence of oxygen on respiration, A., ii, 706.

Pembrey, Marcus Seymour. See also Arthur Philip Beddard.

Pennington, (Miss) Mary Engle, bacterial growth and chemical changes in milk kept at low temperatures, A., ii, 409.

Pérand, J., action of magnesium phenyl bromide on the second methyl ester of p-dimethylamino-o-benzoylbenzoic acid, A., i, 422.

Perkin, Arthur George, note on morindin, P., 149.

Perkin, Arthur George, and Frederick Mollwo Perkin, the electrolytic oxidation of some hydroxybenzoic acids, T., 1186; P., 149.

Perkin, Frederick Mollwo, note on the formation of lead ethoxide, P., 179. electrolytic analysis, A., ii, 432.

Perkin, Frederick Mollwo, and Lionel Pratt, action of metallic calcium and calcium hydride on metallic oxides, sulphides, and halogen salts, A., ii, 379.

Perkin, Frederick Mollwo. See also (Miss) Mary Cunningham, Thomas Weatherill Harrison, Herbert Drake Law, and Arthur George Perkin.

Perkin, (Sir) William Henry, obituary notice of, T., 2214.

Perkin, William Henry, jun., and William Jackson Pope, experiments on the synthesis of 1-methylcyclohexylidene-4-acetic acid,

\[
\text{CHMe}_2\text{CH}_2\text{C}=:\text{CH}_2\text{CO}_2\text{H}.
\]

Part I., T., 1075; P., 145.

Perkin, William Henry, jun., and Robert Robinson, brazilin and hematoxylin. Part VIII. Synthesis of brazilinic acid, the lactones of dihydrobrazilinic and dihydrohematoxylinic acids, anhydrobrazilic acid, &c. The constitution of brazilin, hematoxylin, and their derivatives, T., 489; P., 54.

Perkins, P. B., determination of the molecular weight of radium emanation by the comparison of its rate of diffusion with that of mercury vapour, A., ii, 552.

Peman, Edgar Philip, the direct action of radium on copper and gold, T., 1775; P., 214.

Peman, Edgar Philip, and Richard Henry Greaves, the decomposition of ozone by heat, A., ii, 480.

Perotti, Renato, microbiochemical formation of ammonia in soil, A., ii, 124.

natural factors in the dissolution of tricalcium phosphate in soil, A., ii, 527.

Perrier, Gustave, and H. Caille, formation of mixtures of isomerides of constant melting point in Friedel and Crafts' reaction, A., i, 349.

derivatives of phenyl 3-naphthyl ketone, A., i, 650.
INDEX OF AUTHORS.

Perrin, Jean, the Bose-Guillaume phenomenon and contact electrification, A., ii, 754.

the size of molecules and charge of the electron, A., ii, 927.

Perrot, E., and Eugène Tassilly, "bourgou" (Panicum stagninum), a sacchariferous grass, A., ii, 726.

Perrot, François Louis. See Georges Banne.

Pesez, J., electrolytic estimation of bis-muth, A., ii, 786.

Pestalozza, Ugo. See Roberto Ciusa and Luigi Mascarelli.

Peters, electrolytic inactivity of ferric oxide, A., ii, 387.

Peters, Amos W., the cell and its medium. III. Inorganic salts of the protozoan cell and its medium, A., ii, 209.

chemical and physiological properties of a solution of hydrochloric acid and sodium chloride, A., ii, 411.

Peters, Ernst R. C. See W. Percy Wilkinson.

Peters, F., and Hugo Simonis, 4-methylcoumarin, A., i, 339.

Peters, Walter, a zirconium mercury double salt, A., i, 1092.

connexion between residual affinity and additivity, A., ii, 937.

Petrenko-Kritschenko, Pavel Iv., and L. Dementyeff, tetrahydropryne compounds, A., i, 560.

Petrenko-Kritschenko, Pavel Iv., and W. Petroff, condensation of acetonedi-carboxylic esters with aldehydes under the influence of ammonia and amines. III., A., i, 564.

Pewsner, J. D. See E. S. London.

Pfannenstiel, Adolf. See Richard Willstätter.

Pfeiffer, Paul, stereochromy of chromium. III., A., i, 79.

stereochromy of chromium. IV. The isomeric dibromo-salts, A., i, 79.

isomerism of chromium salts, A., ii, 594.

Pfeiffer, Paul, [with Th. Gassmann and H. Pietsch], stereochromy of chromium. VII. Mixed luteco-salts, A., i, 508.

Pfeiffer, Paul, [with Rudolf Prade and Richard Stern], stereochromy of chromium. V. Stereoisomeric aquo- and hydroxy-salts, A., i, 506.

Pfeiffer, Paul, and M. Tilgner, action of iodine on certain thiocyanates, A., i, 614.

Pfeiffer, Paul, [with W. Vorster and Richard Stern], stereochromy of chromium. VI. Polynuclear chromium salts, A., i, 507.

Pfängler, Eduard [Friedrich Wilhelm], glycogen in frogs during inanition, A., ii, 52.

the capacity of the liver to reverse the optical action of sugars, A., ii, 307.

precipitation of glycogen, A., ii, 329.

Pfy, Balthasar, and Br. Linne, new pressure cylinder, A., ii, 270.

Pfy, Balthasar, and W. Scheitz, constituents of saffron, A., ii, 979.

process for the valuation of saffron, A., ii, 997.

Phelps, Isaac King, Howard E. Palmer, and R. Smillie, influence of catalytic agents in ester formation; effect of certain sulphates on benzoic and succinic acids, A., i, 790.

Phelps, Isaac King, M. A. Phelps, and Ernest A. Eddy, purification of esters, A., i, 758.

influence of catalytic agents in ester formation; hydrogen bromide and zinc bromide in the formation of ethyl benzoate, A., i, 789.

influence of catalytic agents in ester formation; esterification of benzoic acid with certain chlorides, A., i, 790.

Phelps, Isaac King, M. A. Phelps, and R. W. Osborne, esterification of benzoic acid, A., i, 166.

Phelps, Isaac King, and E. W. Tillotson, jun., esterification of malonic acid, A., i, 756.

conversion of ethyl cyanoacetate into ethyl malonate, A., i, 756.

influence of catalytic agents in ester formation; esterification of cyanoacetic acid, A., i, 756.

preparation of malonic acid or its ester from monochloroacetic acid, A., i, 757.

preparation of cyanoacetic acid and its ester from monochloroacetic acid, A., i, 757.

Phelps, Isaac King, and L. H. Weed, use of certain organic acids and acid-anhydrides for the standardisation of alkali and acid solutions, A., ii, 730.

comparison between succinic acid, arsenious oxide, and silver chloride for the standardisation of solutions in iodimetry, alkalimetry, and acidimetry, A., ii, 730.
INDEX OF AUTHORS. 1177

Phelps, Isaac King, L. H. Weed, and C. R. Honsum, action of dry ammonia on ethyl oxalate, A., i, 11.

Phelps, M. A. See Isaac King Phelps.

Philip, James Charles, the refraction and dispersion of triazo-compounds, T., 918; P., 114; discussion, P., 115.

the dissociation constants of triazoaetic and a-triazopropionic acids, T., 925; P., 114; discussion, P., 115.

Philipoff, O. See Vladimir N. Ipatieff.

Philipp, K. See Emilio Noëltling.

Philippi, Emil, Isolation and the chemical precipitation of calcium carbonate from sea-water, A., ii, 302.

Phillips, Harry Edward William, the electrical conductivity of phosphoric acid, P., 239.

Phillips, Henry Ablett. See Oswald Silberrad.

Philoche, (Mlle.) Ch., Physico-chemical investigation of amyrase and maltase, A., i, 712; ii, 470.

Piasecki. See Leon Marchlewski.

Picard, Jean. See Richard Willetätter.

Pick, Ernst Peter, and Friedrich Pineles, the relationship of the thyroid gland to the physiological action of adrenaline, A., ii, 875.

Pick, Hans. See Otto Sackur.

Pickard, Robert Horson, and William Oswald Littlebury, the isomeric menthols, P., 217.

Pickard, Robert Horson, and Joseph Yates, contributions to the chemistry of the cholesterol group. Part I. The action of hydrogen peroxide and of fused potassium hydroxide on cholesterol, T., 1678; P., 121, 199. contributions to the chemistry of the cholesterol group. Part II. Some oxidation products of sitosterol, T., 1923; P., 227.

the action of fused potassium hydroxide and of hydrogen peroxide on cholesterol; preliminary note, P., 121.

Pickles, Samuel Shrowder, the constituents of Cyprus organum oil; isolation of a new terpene (organene), T., 862; P., 91.

Pidduck, F. B. See E. W. B. Gill.

Pier, Mathias, specific heat and dissociation of chlorine, A., ii, 352.

Pierart, Joseph, detection of levulose in presence of other natural sugars, A., ii, 542.

test for pentones with orcinol and hydrochloric acid, A., ii, 903.

Pierron, Paul, aromatic monatomic cyanamides, A., i, 925.

Piesczek, Ernst, assay of red lead, A., ii, 228.

Pietzsch, H. See Paul Pfeiffer.

Piettre, Maurice, glycocholic acid, A., i, 959.

bile and biliary pigments, A., ii, 408.

Pignet, P. See Alfred Guyot.

Pigorini, Luciano, toxicity of silver salts to fishes, A., ii, 412.

behaviour of dextrosephenylasazone in the organism, A., ii, 876.

Pillai, N. K. See Felix Löhnis.

Pillow, Albert. See Otto Diels.

Pilz, Ferdinand, relation between the increased yield due to phosphatic manure and the amount of phosphoric acid in the soil, A., ii, 423.

Pincussohn, Ludwig, the influence of colloids on ferments, A., ii, 308.

Pineles, Friedrich. See Ernst Peter Pick.

Pinna, Giuseppe. See Efiisio Mameli.

Pinnow, Johannes, the reduction [of the photographic image] with persulphate and according to Farmer, A., ii, 245.

Pisovski, Itie J., a-anthamidine and 1,4-anthradiamine, A., i, 481.

Pissarjewsky, Leo, the atomic hypothesis and the energetic theory of the universe, A., ii, 478.

existence of different modifications of ordinary grey silver, A., ii, 494.

Pissarjewsky, Leo, and E. Karp, relation between the diffusion constant, internal friction, and electrical conductivity, A., ii, 566.

Pissarjewsky, Leo, and A. Levites, influence of the solvent on the equilibrium constant, A., ii, 570.

Pitoni, R., a lecture voltmeter, A., ii, 657.

Pituti, Arnaldo, maleic and fumaric derivatives of p-aminophenols, A., i, 783.

Pituti, Arnaldo, and Gennaro Magli, absorptive power for air of certain varieties of vegetable carbon, A., ii, 585.

Pizzighelli, R. See Arturo Miolati.

Plant, O. H., absorption of fat from intestinal loops in dogs, A., ii, 1050.

Plato, Wilhelm, solidification phenomena exhibited by inorganic salts and salt mixtures, A., ii, 758.
INDEX OF AUTHORS.

Pleissner, Max, solubility of certain lead compounds in water, A., ii, 40.
Pimmer, Robert Henry Aders, the proteins of egg-yolk, T., 1600; P., 190.
sodium antimonyl tartrate, A., i, 129.

Richmond, Henry Droof, studies in steam distillation and the recovery of amyl alcohol from the acid liquors obtained in the Gerber process, A., i, 495.

studies in steam distillation; formic and acetic acids, A., i, 754.

estimation of nitrogen, A., ii, 530.

Richter, O. K. See Hermann Pauly.

Richter, P. See Wilhelm Manchot.

Rieck, Eduard, certain properties of the radium atom, A., ii, 6.

Riedel, Adolf, condensation of aldol and crotonaldehyde with malonic acid, A., i, 501.

action of ammonia and amines on cinnamylacrylic [cinnamylidene-acetic] acid and its methyl ester, A., i, 536.

Riedel, J. D., preparation of aminoalcohols, A., i, 250, 956.

preparation of eugenyl o- and m-amino-benzoates, A., i, 338.

preparation of alkyl camphorates, A., i, 352, 809.

preparation of choline from lecithin, A., i, 395.

preparation of morphine alkyl bromides, A., i, 452.

preparation of the alkyl halides of dialkylaminodimethylethylcarbinol and their benzoyl derivatives, A., i, 607.

preparation of santalyal camphorate, A., i, 664.

preparation of acylated aminoalcohol esters, A., i, 769.

action of ozone on thebaine, A., i, 1006.

Rieff, A. See Fritz Haber.

Ries, Chr., anomalous behaviour of selenium, A., ii, 343.

Riesenfeld, Ernst Hermann, and Alfred Wesch, higher oxidation products of chromium. IV. Chromium tetroxide compounds, A., i, 963.

decomposition of chromic acid by hydrogen peroxide, A., ii, 951.

Ries, L., poisoning with potassium chlorate, A., ii, 1062.

Risser, O. See Peter Rona.

Riiher, C. N., oxidation of allocinamic acid, A., i, 639.

Rilliet, Auguste. See Emil Abderhalden.

Rimari, Carlo, mineralogy of Sardinia. II., A., ii, 863.

Rimach, [Friedrich] Eberhard, and Edmund Heiten, saccharin and alkali saccharinates, A., i, 394.

Rimele, Eugen. See Theodor Curtius.

Rimpel, Chaim. See Heinrich Biltz.

Rindl, M., and Hugo Simonis, the estimation of lead, copper, and silver in complicated organic salts, A., ii, 432.

Ringe, Oskar. See Franz Fischer.

Rinne, Fritz, and H. E. Boecke, El Inca meteoric iron, A., ii, 303.

Ripke, O. See Reginald Oliver Herzog.

Ritz, W., spectra of the alkali [metals], A., ii, 445.

new law of series spectra, A., ii, 786.

Rikkind, E. See E. S. London.

Roaf, Herbert Eldon, application of Barfoed's reagent to show the hydrolysis of disaccharides by enzymes, A., i, 503.

separation of hippuric acid from urine, A., i, 534.

colorimetric method applicable to both peptic and tryptic enzymes, A., ii, 743.

Roaf, Herbert Eldon. See also L. Adamson and Benjamin Moore.

Robertson, Charles A. See William Jay Hale.

Robertson, Philip Wilfred, orthobromophenols and some bromonitrophenols, T., 788; P., 73.

the melting points of the anilides, p-toluidides, and naphthaldies of the normal fatty acids, T., 1033; P., 120.

Robertson, T. Braidsford, applicability of the laws of amphoteric electrolytes to serum globulin, A., i, 929.
Robertson, T. Brailsford, influence of temperature on the solubility of casein in alkaline solutions, A., i, 930.

dissociation of solutions of the basic caseinates [caseinogenates] of sodium and ammonium, A., i, 1027.

adsorption and the behaviour of casein in acid solutions, A., ii, 89.

the superficial layer of cells and its relation to their permeability and to the staining of tissues by dyes, A., ii, 120.

dissociation of casein, A., ii, 818.

Robertson, T. Bralsford, and C. L. A. Schmidt, part played by alkali in the hydrolysis of proteins by trypsin, A., i, 843.

Robin, Lucien, detection of benzoic acid in butter, A., ii, 1078.

Robinson, William O. See Frank Kenneth Cameron and Charles Lathrop Parsons.

Rödiger, Martin. See Edgar Wedekind.

Römer, Fritz. See Otto Fischer.

Römer, Hermann. See Alfred Thiel.

Roesicke, Adolf. See Emil Fromm.

Rösing, Georg, new apparatus for showing the ammonia-condensation power of soils, A., ii, 620.

Roesler, A., [preparation of vanillin from guaiacol], A., i, 548.

Röttgers, Kurt. See Richard Josef Meyer.

Rogerson, Harold. See Frederick Belling Power.

Rogovskv, E., change in the hydrogen spectrum under the prolonged action of strong electric discharges, A., ii, 335.

Rogozinski, Felix, the protein peptones. III. and IV., A., i, 487.

Rohdich, O. See Hermann Matthes.

Dulong and Petit's law, A., ii, 459.

relation of changes of solubility of calcium sulphate and its rate of hydration, A., ii, 842.

Rohner, Josef, [reactivity of diazo-salts of 2:5-dichloroaniline], A., i, 482.

Roka, K. See Carl Liebermann.

Rolker, H. F. See John Bishop Tingle.

Rolla, Luigi, aminophenylcarbamide and aminophenylthiocarbamide, A., i, 473.

Rolle, Johannes. See Richard Wolffenstein.

Rollett, Adolf. See Johann Feigl.

Roloff, Max, analysis of natural mineral waters, A., ii, 231.

Romburgh, Pieter van, lupeol, A., i, 39.

Rona, Peter, and Leonor Michaelis, sugar in blood, A., ii, 117.

Rona, Peter, and O. Riesser, hippingamelin. I., A., i, 1028.

Rona, Peter. See also Leonor Michaelis.

estimation of ammonia in urine, A., ii, 983.

Ronnet, Leon, estimation of potassium in soils, A., ii, 534.

Rorive, E. See Bernhard Tollens.

Roschdestvensky, M. S. See Antony G. Dorschewsky.

Rosenberg, E. See Carl Neuberg.

Rosenberg, Paul, condensation of formaldehyde and lactose, A., i, 320.

Rosenberg, T. See Alfred Gigon.

Rosenberger, Franz, inosite in animal tissues and fluids, A., ii, 873.

inosite [in flesh], A., ii, 1055.

Rosenblatt, M. See Gabriel Bertrand.

Rosenhaupt, W. See Edward Jordis.

Rosenheim, Arthur, antimony thiglycollate; correction, A., i, 246.

Rosenheim, Arthur, and Abraham Garfunkel, halogen compounds of molybdenum and tungsten. IV. Thioyanates of tervalent molybdenum, A., i, 614.

Rosenheim, Arthur, and Heinrich Loebel, sulphate of tervalent uranium, A., ii, 294.

Rosenheim, Arthur, and Max Pritze, molecular weight and hydrates of hypophosphoric acid, A., ii, 942.

Rosenheim, Otto, and M. Christine Tebb, protogon, A., i, 488.

optical activity of "protagon"; a new physical phenomenon observed in connexion with the optical activity of so-called "protagon," A., ii, 879.

Rosenheim, Otto. See also Frank S. Locke.

Rosenstein, M. See H. Cantoni.
fermentation of malic acid in the production of wine, A., ii, 772.
influence of the sterilisation temperature of grape juice and of the fermentation temperature on the "boquet" of wine, A., ii, 773.

Rosenthal, Isidor, decomposition of complex chemical compounds in a variable magnetic field, A., ii, 152.

Rosenthaler, Leopold, amygdalin, A., i, 197.
dercomposition of amygdalin by emulsion, A., i, 817.
volumetric estimation of magnesium, A., ii, 67.
avanill-hydrochloric acid as a test for albumin and tryptophan, A., ii, 76.
de colouring action of charcoal, A., ii, 158.

Wegscheider, Rudolf, and Hugo Strauch, esterification of unsymmetrical di- and poly-basic acids. XXII. Isomerism of methyl nitroheminates, A., i, 794.

Wehnelt, Arthur [Rudolph Berthold], Wehnelt cathode in high vacua, A., ii, 147.

Weichhold, Oskar. See Emil Fischer.

Weigert, Fritz, photochemical reactions. II. Gaseous reactions which are photochemically sensitised; a theory of the catalytic influence of light, A., ii, 5.

thermodynamic treatment of photochemical processes, A., ii, 748.

photochemical reactions. III. Decomposition of ozone by light, A., ii, 914.

Weil, Hugo, preparation of aromatic o-hydroxyaldehydes, A., i, 800.

Weil, Lotte, p-dimethylaminocinnamic acid, A., i, 982.

Weimann, P. P. von, colloidal, amorphous, and crystalline states, A., ii, 90.

the crystalline state as a general property of matter, A., ii, 263.

modification of Wolfgang Ostwald’s system of colloids, A., ii, 820.

preparation of colloidal amorphous forms of crystalline and soluble salts of the alkaline-earth metals, A., ii, 842.

the liquid-crystalline state as a general property of matter, A., ii, 1023.

Weingarten, Fred S., and Burrill B. Crohn, influence of internal haemorrhage on protein metabolism, A., ii, 710.

Weiniger, E. See Georg Lockemann.

Weinland, Rudolf Friedrich, salts of an acetachromo-base, A., i, 847.

Weinland, Rudolf Friedrich, and F. Reischle, hydrofluorides of some, in part very weak, organic bases, A., i, 974.

Weinschenk, Arthur, behaviour of gelatin solutions towards naphthols or mixtures of naphthols with formaldehyde, A., i, 377.

Weisberg, Julius, a levarotatory substance found in altered beetroot, A., i, 505.

Weiss, Eugen. See Fritz Fichter.

Weiss, Pierre. See also A. Cotton.

Weissgerber, Rudolf, sodium derivative of fluorene, A., i, 873.

Weisweiler, Gustave. See Gabriel Bertrand.

Weitenböck, Richard. See Hugo Schröter.

Weitzner, Emil, dimethylglycoluril and \( \beta \)-methylhydantoin, A., i, 841.

Weizmann, Charles. See William Henry Bentley.

Welker, William H. See also Louis Hussakof.

Weller, Arnold. See Emil Fromm.

Wellmann, O., metabolism of calcium, magnesium, and phosphorus during inanition, A., ii, 306.

Wells, Harry Gideon, fats and lipoids of malignant hypernephromas, A., ii, 411.
the liver in chloroform necrosis (delayed chloroform poisoning), A., ii, 974.
Wells, Horace Lemuel, See George Samuel Jamieson.
Welsch, Carl Auer von, resolution of ytterbium into its elements, A., ii, 591.
Welsch, A. See Adolf Windaus.
Wendel, Adolf. See Felix Ehrlich.
Wenzel, Franz. See Franz Haisler.
Werner, Alfred, theory of mordant dyes, A., i, 669.
1:2-dichlorotetramminecobalt salts; ammoniovioleosalts, A., ii, 42.
complex metal ammonia derivatives. VI. Octammine-a-amino-ol-dicobalt salts
\[ (NH_4)_2CO\cdot NH_2\cdot CO(NH_4)_4 \cdot OH_2 \]
A., ii, 42.
iodopentamminecobalt salts, A., ii, 950.
Werner, Alfred, [and, in part, Emil Bindschedler and Adolf Grün],
complex metal ammonia compounds. VII. Hexamminetridicobalt salts, A., ii, 43.
Werner, Alfred, [with Johann Jovonvits, Gabriel Aschkinasy, and Josef Possett],
metallic salts of organic acids. I. Formates and acetates of chromium, A., i, 935.
Werner, Alfred, [with Ernst Thomann],
theory of mordant dyes, A., i, 440.
Wersilowa, M. A. See E. S. London.
Wesch, Alfred. See Ernst Hermann Riesenfeld.
Wesendonk, Karl von, the Swan spectrum, A., ii, 241.
Westenryk, N. von, reaction of the blood after intravenous injection of acid and alkali, A., ii, 1048.
Weston, Frank Edwin, explosive crystallisation, A., ii, 759.
Weston, Frank Edwin, and Henry Russell Ellis, action of aluminium powder on silica and boric anhydride, A., ii, 385.
interaction of aluminium powder and carbon, A., ii, 849.
Weyberg, Zygmunt, the alumino-silicate, \( K_2 Al_5 Si_3 O_{10} \), A., ii, 697.
the potassium alumino-silicate, \( K_2 Al_5 Si_3 O_{10} \), A., ii, 697.
sodium chromasilicates, A., ii, 857.
Wheeler, Alvin Sawyer, [with C. W. Miller, W. S. Dickson, and Stroed Jordan], condensation of chloral with primary aromatic amines. II., A., i, 332.
halogen amino-acids; p-iodophenylalanine, A., i, 981.
pyrimidines. XXXII. Synthesis of uracil-4-acetic acid, A., i, 693.
Wheeler, Homer Jay. See Burt Laws Hartwell.
White, Charles Powell, so-called fatty degeneration of the suprarenal, A., ii, 968.
crystals in tumours, A., ii, 972.
Whiteley, (Miss) Martha Annie, liberation of iodine from hydriodic acid by certain halogenated malonyl derivatives, P., 238.
Whitney, James Lyman. See Wilhelm Faltta.
Whymper, Robert. See Robert John Caldwell.
Wibaut, J. P. See Andreas Smits.
Wichern, G. See Wilhelm Meigen.
Wichern, Heinrich, estimation of the reducing power of bacteria and animal organs, A., ii, 1063.
Widdows, (Miss) Sibyl T. See William Hobson Mills.
Widemann, Max, apparatus for the estimation of carbon in iron, A., ii, 984.
Widmann, Karl Th. See Julius Schmidt.
INDEX OF AUTHORS.

Wischowski, Wilhelm, the importance of allantoin in uric acid metabolism, A., ii, 119.

Wiegner, G. See Arthur Hantzsch.

Wieland, Heinrich, decomposition of tetra-arylhazines. IV., A., i, 1014.

Wiesner, Joseph. See Karl Bernhard Lehmann.

Wild, A. See Louis Pelet-Jolivet.

Wild, Henry, the atomic weight of radium, A., ii, 141.

Wildt, Edwin. See Gustav Frericha.

Wildt, J. C. de Kuyter de. See Bounce Sjollema.

Wilks, Leopold. See Viktor Zailer.

Wilke, Ernst. See Georg Bredig.

Wilkinson, W. Percy, and Ernest R. C. Peters, a new reaction for distinguishing between heated and unheated milk, and for the detection of hydrogen peroxide in milk, A., ii, 907.

Wille, Arwed, the action of sulphur dioxide on plants, A., ii, 887.

Wien, Wilhelm, nature of the positive rays, A., ii, 1006.

Wien, Wilhelm, constitution of the glyoxime peroxides, A., i, 108.

Wieland, Heinrich, and Hans Stenzl, phenylisocrotophenone, A., i, 35.

Wilcox, Burton B. See William Maurice Dehn.

Wilcox, W. G. See Ebenezer Henry Archibald.

Wilcox, (Miss) Edith Gertrude, crystalline egg-albumin, A., i, 485.

Wilcox, Oswin W., decomposition curves of some nitrocelluloses of American manufacture, A., i, 606.

Wilkert, Walter. See August Michaelis.

Willgerodt, [Heinrich] Conrad [Christoph], three lecture experiments on the preparation of iodochlorides and iodoxy- and iodonium-compounds, A., i, 408.

Willgerodt, Conrad, and Rudolf Gartner, derivatives of 2-ido-p-toluidine and 2-ido-4-nitrobenzoic acid containing uni- and ter-valent iodine, A., i, 876.

Williams, Elbrick. See William Maurice Dehn.

Williams, Leon Franklin. See John Bishop Tingle.

Williams, Owen Thomas, microchemical changes occurring in appendicitis, A., ii, 1057.

Willke, Johannes. See Karl Bernhard Lehmann.

Willner, Kurt. See Kurt Arndt.

Willstätter, Richard [Martin], and Max Benz, chlorophyll. VI. Crystalline chlorophyll, A., i, 189.

Willstätter, Richard, and James Bruce, constitution of cyclobutene, A., ii, 402.

Willstätter Richard, and Heinrich Kubli, reduction of nitro-compounds by Zinin's method, A., i, 522.

Willstätter, Richard, and Erwin W. Mayer, reduction with platinum and hydrogen at the ordinary temperature. I., A., i, 383.

reduction with platinum and hydrogen. II. Dihydrocholesterol, A., i, 636.

Willstätter, Richard, and Fritz Müller, quinonoid compounds. XV. Two forms of o-quinones, A., i, 731.

Willstätter, Richard, and Jean Piccard, quinonoid compounds. XV. Wurster's dye salts, A., i, 475.

quonoid compounds. XVII. meri-Quinoneiminines. II., A., i, 915.

Wilsmore, Norman Thomas Mortimer, and Alfred Walter Stewart, keten, A., i, 318.

Wilsmore, Norman Thomas Mortimer. See also (Miss) Frances Chick and Frederick Murray Godsllall Johnson.
Wilson, F. B. See Frederick Hutton Getman.
Wilson, John Hunt. See Gregory Paul Baxter.
Wilson, R. A. See Wilhelm Cramer.
Wilson, Robert William. See Albert Ernest Dunstan.

Winans, Paul, preparation of nitrogen peroxide, A., ii, 487.
Windaus, Adolf, cholesterol. X. and XI., A., i, 264, 728.
Windaus, Adolf, and Wilhelm Vogt, a-chloro-β-iminazolylpropionic acid, A., i, 694.
Windaus, Adolf, and A. Welsch, resin of Antiaris toxicaria, A., i, 903.
Windisch, Wilhelm, phosphoric acid in barley, A., ii, 528.
Winiwarter, E. von. See Lucien Louis de Koninck.

Winogradoff, N. See Alex. Bogojawelsky.
Winterberg, Heinrich, influence of certain poisons in the fibrillary contraction of the heart, A., ii, 521.
Winterfeld, G. See David Holde.
Winterstein, Ernst [Heinrich], and O. Hiestand, vegetable phosphatides. II., A., ii, 218.
Winterstein, Hans, respiratory metabolism of the isolated spinal cord of the frog, A., ii, 509.

Winzheimer, Erich, identity of methylsticel and piperonyleneacetone, A., i, 656.
kawa root [of Piper methysticum], A., i, 804.

Wirth, Fritz, transition concentrations. I. Conversion of lanthanum oxalate into sulphate by sulphuric acid, A., ii, 570.

Wirth, Fritz. See also Hugo Erdmann and Otto Hauser.
Wislizenius, Hans, fibre-like developed alumina (fibre-alumina) and its surface actions (adsorption), A., ii, 261.
filtration apparatus, A., ii, 576.
Wislizenius, Wilhelm, and Paul Berg, desmotropy and fluorescence of ethyl oxalosuccinonitrile, A., i, 965.

Wislizenius, Wilhelm, and Martin Waldmüller, condensation of fluorene with alkyl nitrites and nitrates by means of potassium ethoxide, A., i, 973.

Withrow, James R., influence of temperature on the electrolytic precipitation of copper from nitric acid, A., ii, 492.

Witt, Otto Nikolaus, and Erhard Witt, nitration of aniline and its derivatives, A., i, 874.
Witt, Reinhold. See Hugo Schrötter.
Witte, A. See Walther Borsche.
Witte, Erhard. See Otto Nikolaus Witt.

Witte, Karl. See Richard Meyer.
Wittmann, J. See Emil Fromm.
Witzmann, W. See Lothar Wöhler.
Wöhler, Lothar, and W. Becker, colour and composition of Guignet's green, A., ii, 765.

Wöhler, Lothar, and C. Condrea, different colours of ferric oxide, an effect of the size of the grains, A., ii, 287.

Wöhler, Lothar, W. Plüddemann, and Paul Wöhler, new method for determining the tension of sulphates, A., ii, 290.
sulphuric acid contact process, A., ii, 581.

Wöhler, Lothar, and W. Witzmann, oxides of iridium, A., ii, 300.

solid solutions in the dissociation of iridium oxides, A., ii, 301.

Wöhler, Lothar, and Paul Wöhler, dissociation of chromium oxides and of the double oxides of chromium and copper, A., ii, 387.

Wöhler, Paul. See Lothar Wöhler.

Wöbling, Hans, nitrogen sulphide, A., ii, 272.

Woelfel, Albert, distribution of the salts in haemolysins, A., ii, 492.

Wörner, Emil, bismuth cholate, A., i, 398.
simple arrangement for continuous extraction with a solvent of inconstant boiling point, A., ii, 681.

Wogau; Max von, calculation of the diffusion constants of non-electrolytes in solution, A., ii, 817.

Wohl, Alfred, aminoacets and aminoaldehydes, A., i, 46.

Wohl, Alfred, and E. Grosse, a tertiary triacetal base and arecaidinealdehyde, A., i, 49.

Wohl, Alfred, and A. Johnson, arecaidine and arecoline, A., i, 49.

Wohl, Alfred, and M. Lange, anilinoacetal, A., i, 17.
synthesis of lactaldehyde, A., i, 943.
Wohl, Alfred, and M. S. Losanitsch, tetrahydropridine-3-aldehyde and piperidine-3-aldehyde, A., i, 46.

synthesis of the racemic cinchoneloupeic acids, A., i, 47.

1-ethylisoacic acid and α-amino-1-ethyl-β-pipecoline, A., i, 50.

α-methylallyl alcohol (α-buten-γ-ol), A., i, 934.

Wohl, Alfred, [with Hugo Schweitzer, A. Köppen, Heinrich Roth, and M. Lange], the tricarbon series, A., i, 941.

Wohlers, Hans Emil, adsorption phenomena of inorganic salts, A., ii, 819.

Wohlgemuth, Julius, investigation of diastases, A., ii, 403.

a new method for estimating diastatic ferments, A., ii, 444.

Wohlgemuth, Julius. See also Ernst Fuld.

Wolfe, improved pipette, A., ii, 827.

Wolf, Charles George Lewis. See also Adolf Loewy, W. McKim Marriott, and Emil Osterberg.

Wolf, A. See Richard Wolfenstein.

Wolf, Jules, some mineral waters which play the part of peroxydases, A., i, 187.

some artificial peroxydases; the important rôle of iron in their action, A., i, 490.

detection of methyl alcohol in fermented liquids, A., ii, 72.

artificial peroxydases, A., ii, 573.

some oxydasic phenomena produced by colloidal ferrous ferrocyanide, A., ii, 1022.

Wolf, Jules, and E. de Stocklin, influence of certain iron compounds and of peroxydases on the catalysis of hydriodic acid by hydrogen peroxide, A., i, 746.

Wolff, Jules. See also C. Gessard.

Wolff, Ludwig, and Wilhelm Schreiner, lactones of the pyrazole series, A., i, 291.

Wolfenstein, Richard, and O. Bötgers, preparation of aromatic hydroxylated nitro-compounds, A., i, 629.

barium percarbonate [barium dioxide carbonate], A., ii, 183.

Wolfenstein, Richard, and Johannes Rolle, halogen-substituted tropeines, A., i, 282.

Wolfenstein, Richard, and A. Wolff, pseudomorphism of organic persulphates, A., i, 283.

Wolfenstein, Richard. See also T. Kumagai.

Wolgast, Karl. See Max Bodenstein.

Wologdine, S. See Henri Le Chatelier.

Wolter, Ludwig, preparation and properties of zirconium tetrafluoride, A., ii, 701.

generation of oxygen in a Kipp’s apparatus, A., ii, 1028.

Wolter, Ludwig. See also Friedrich Willy Hinrichsen.

Woltereck, Herman Charles, synthesis of ammonia and of hydrogen cyanide, A., i, 400.

temperature of dissociation of ammonia and of carbon monoxide, A., ii, 820.

Wood, Horatio C., modification of the Soxhlet extractor, A., ii, 424.

Wood, Robert Williams, the existence of positive electrons in the sodium atom, A., ii, 150.

anomalous magnetic electrons in the sodium atom, A., ii, 150.

the resonance spectra of sodium vapour, A., ii, 546.

Woodhams, Edwin LeGrand. See Edward DeMille Campbell.

Woodiwiss, George, chemical elements; periodicity, weight, and valency, A., ii, 368.

non-metallic elements in connexion with valency and specific gravity, A., ii, 574.

Woodman, Alpheus Grant, and A. L. Burwell, detection of formic acid in foods, A., ii, 639.

Woog, Paul. See Leon Brunel.

Woolley, W. J., temperature-coefficient of rate of conduction and latent period in muscle, A., ii, 711.

Wootton, Fred. See John Kenneth Harold Inglis.

Zwayer, Felicia, and Stanislaus von Kostanecki, [with (Frl.) M. Szwejkowska], function of the double chromophore, CO.C:C, A., i, 443.
INDEX OF SUBJECTS.

TRANSACTIONS, PROCEEDINGS, AND ABSTRACTS.

1908.

(Marked T., P., and A., i and A., ii respectively.)

A.

Abrastol (VITALI), A., ii, 642.

Absorption, laws of, in the alimentary canal (LONDON and SANDBERG; LONDON), A., ii, 870.

in the intestine, relationship of concentration to (LONDON and POLOWZOWA), A., ii, 1050.

of carbohydrates (LONDON and POLOWZOWA), A., ii, 870.

of fat from intestinal loops in dogs (PLANT), A., ii, 1050.

of meat in the intestine (LONDON and SULIMA), A., ii, 870.

of optically isomeric substances from the intestine, relative rate of (DAKIN), A., ii, 710.

and assimilation of phosphorus organic compounds (MARFORI), A., ii, 1052.

of poisonous gases by the respiratory tract (LEHMANN, WtNt, WILKt, and YAMADA), A., ii, 771.

of protein (v. KORtS), A., ii, 960.

of proteins rich in bases (LONDON), A., ii, 870.

of iodiised proteins (v. FURTt AND FRIEDMAN), A., ii, 1050.

of tubercle bacilli (LONDON and RlWtKIND), A., ii, 870.

Absorption spectra. See under Photochemistry.

Acaroid resin oil (HAENSEL), A., i, 665.

Accipenser Guldenstädtii. See Sturgeon, Caspian.

Accumulator. See under Electrochemistry.

Acnaphthene styphuate (GIRSON), T., 2098; P., 241.

Acnaphthene, 4-chloro-, and its picrate (CHRtfttON AND CRtYAX), P., 241.

Acet-. See also Aceto-, Acetoxy-, Acetyl-, and under the parent Substance.

Acetal, $C_{13}H_{19}O_3N$, from alcohol, sodium ethoxide, sodium iodide, formamidile, and chloroacetetal (WOHL and LANGE), A., i, 17.

Acetal, amino-, synthesis of derivatives of (FISCHER), A., i, 54, 887.

Acetals, formation and hydrolysis of (FITZGERALD AND L copingworth), P., 153.

preparation of (Hess), A., i, 762.

preparation of, by Claisen's method (ARBUSOFF), A., i, 555.

Acetals, sec.-amino-, preparation of (PAAL AND VAN GEMBER), A., i, 511.

Acetaldehyde, formation of, in alcoholic fermentation (TRILLAT; KAYSER AND DEMOLON), A., i, 317.

formation and disappearance of, under the influence of yeasts (TRILLAT AND SAUTON), A., ii, 615.

condensation products of, containing six and ten atoms of carbon (Zeisel and v. BITtO), A., i, 761.

copper compound (MAKtOWKA), A., i, 328.

Acetaldehyde, amino-, phenylsoazone of (NEUBERG), A., i, 323.

bromo-, preparation of, and its diurethane (MAUGUN), A., i, 941.

Acetamide, platinozous (HOFMANN AND BUGGE), A., i, 141.

Acetamide, bromo-, modification of the preparation of methylamine from (FRANCOIS), A., i, 966.

dichloronitro- (STEINKOPf AND KIRCHHOFF), A., i, 963.

halogen derivatives, action of phosphorus pentachloride on (STEINKOPF, BENEDERK, GRUNUP, AND KIRCHHOFF), A., i, 961.

iodo-, compound of, with dimethylamidine (v. BRAUN), A., i, 629.
Acetanilide, 2:6-di-bromo- and m-nitro-, and its halogen derivatives (Körner and Contardi), A., i, 524.

Acetanilide, o-chloro-derivatives (Schwalbe, Schulz, and Jochheim), A., i, 974.

Acetanilides, m-cyano-derivatives (Pierron), A., i, 926.

Acetanilides, halogen derivatives (Mannino and Di Donato), A., i, 826.

2:4:5-triiodo- and 4- and 6-iodo-3-nitro-, and 2:4:6-diiodo-3-nitro- (Körner and Belasio), A., i, 778.

Acetatochromo-base, o-nitro- and o-nitroso-crystallography of (Jaeger), A., i, 147.

Acetimide, p-nitroso-, i, 155.

Acetic acid, chloro-, condensation of, with p-diaminodiphenylmethane (Neumüller), A., i, 369.

Acetic acid, and its ester, preparation of cyanoacetic acid from (Phelps and Tillotson), A., i, 757.

Acetic acid, preparation of malonic acid and its ester from (Phelps and Tillotson), A., i, 757.

dichloro-, action of, on aniline and its homologues (V. Ostromissensky), A., i, 82, 888; (Heller and Leyden), A., i, 216.

Acetic acid, trichloro-, esterification of (Kailan), A., ii, 936.

cyano-, and its ester, preparation of, from chloroacetic acid (Phelps and Tillotson), A., i, 757.

Acetic acid, salts, of, with carbanilides (Baum), A., i, 253.

Acetic acid, esterification of (Phelps and Tillotson), A., i, 756.

Acetic acid, ethyl ester, action of phenylthiocarbimide on (Ruhemann), T., 621; P., 53.

Acetic acid, conversion of, into ethyl malonate (Phelps and Tillotson), A., i, 756.

Acetic acid, imino-, methyl ester (Curtius, Darapsky, and Müller), A., i, 145.

Acetic acid, iodo-, 7-methyl ester, and its reaction with ammonium bases (E. and O. Wendeckind), A., i, 258.

Acetic acid, nitrosoimino-, methyl ester, azoimide, and hydrazide and its dibenzylidene derivative (Curtius, Darapsky, and Mülle), A., i, 145.

Acetic anhydride, compounds of, with acetates (Franzen), A., i, 937.

Acetic anhydride, as reagent for distinguishing between enolic and ketonic modifications (Michael and Murphy), A., i, 949.

Acetic anhydride, iodo- (Abderhalden and Guggenheim), A., i, 886.

Acetic fermentation. See under Fermentation.

Acetimide chloride, nitro- (Steinkopp and Bohrmann), A., i, 328.

Aceto- See Acet-, Acetoxy-, Acetyl-, and under the parent Substance.

Acetoacetic acid, synthesis of, by perfusion through the liver (Friedmann), A., ii, 205, 719.

Acetoacetic acid, formation of, in the liver (Embden and Engel), A., ii, 515.

Acetoacetic acid, formation of, in the liver of diabetic dogs (Embden and Lattes), A., ii, 515.

Acetoacetic acid, degradation of, in the animal body (Embden and Michaud) A., ii, 515, 967.
Acetoacetic acid, and acetone, Folin's method of separating, in urine (Hart), A., ii, 742.

Acetoacetic acid, ethyl ester, isomerism of (McCrea), A., i, 759.

condensations with, and their reversion (Dieckmann and Kron), A., i, 388.

condensation of, with alkylguanidines (Majima and Kobayashi), A., i, 222.

calcium derivative (Erdmann and van der Smissen), A., ii, 589.

Acetoacetic acid, α- and γ-bromo-, esters, action of diazo-chlorides on (Favrel), A., i, 209.

γ-γ-dibromo-, ethyl ester (Favrel), A., i, 209.

γ-bromo-α-cyano-, γ-chloro-α-cyano-, and γ-γ-dicyano-, ethyl esters, and their derivatives (Benary), A., i, 600.

iso-nitroso-, ethyl ester, benzoylhydrzone of, and its fission products (Bulow and Schaub), A., i, 637.

Acetoacetic ester synthesis, mechanism of the (Clark), A., i, 124.

Aceto and β-naphthalides, halogen derivatives of (Mannino and di Donato), A., i, 827.

Acetonazine, iso-nitroso- (Ponzi and Giovetti), A., i, 834.

Acetone and chloroform (Dott), A., i, 306.

benzene, and toluene, dispersion in the electric spectra of (Colley), A., ii, 909.

vapour pressure of aqueous solutions of (Markovitski), A., ii, 353.

reaction of, with mercuric iodide in alkaliine solution (Marsh and Struthers), P., 266.

condensation of, with oxalic ester (Clark), A., i, 124.

oxidation of (Fournier), A., i, 247.

formation of, in the animal body (Friedmann; Dakin), A., ii, 719; (Knoopp), A., ii, 720.

formation of, from αβ-unsaturated acids by perfusion through the liver (Friedmann), A., ii, 719.

formation of, in the liver (Emden and Marx), A., ii, 515.

estimation of (Hrikel), A., ii, 235.

estimation of, in urine (Hart), A., ii, 783.

and acetoacetic acid, Folin's method for separating, in urine (Hart), A., ii, 742.

Acetone bases, cyclic, condensation of, with benzaldelyde (Pauly and Richter), A., i, 235.

Acetonedi-carboxylic acid, esters, condensation of, with aldehydes under the influence of ammonia and amines (Petrenko-Kritschenko and Petroff), A., i, 564.

Acetonedi-methyl- and -ethyl acetals, αα-dichloro- (Woehl and Koppen), A., i, 942.

Acetonehæmin (Mernowicz and Zaleski), A., i, 232.

Dennstedt's method for the analysis of (Zaleski), A., ii, 132.

Acetonitrile, additive compound of, with silicon tetrabromide (Reynolds), P., 280.

bromo-, new method of preparing, and its addition to tertiary bases and alkaloids (v. Braun), A., i, 675.

bromo-, chloro-, and iodo-derivatives, preparation of (Steinkopf), A., i, 720.

iodo-, synthesis of (v. Braun), A., i, 627.

nitro-, and its salts, and dibromonitro- (Steinkopf and Bohrmann), A., i, 327.

Acetonitriles, arylsulphonated (Tröger and Lindner), A., i, 633.

and their condensation with aromatic aldehydes and with amyl nitrite and sodium ethoxide (Tröger and Prochnow), A., i, 798.

Acetonylacetonc, condensation of, with nitromonaldehyde (Hale and Robertson), A., i, 634.

Acetonylacetonc-p-nitrophenylosazone (Auwers and Hessenland), A., i, 592.

Acetonylazoimide. See Triazoacetone.

2-Acetonylphenol, 4-nitro-, and its methyl and ethyl ethers and oxime, and 4:6-dinitro-, and its ethyl ether (Hale and Robertson), A., i, 634.

Acetophenone, reaction of, with mercuric iodide in alkaline solution (Marsh and Struthers), P., 267.

fixation of, by benzoylacrylic acid (Bougauf), A., i, 796.

Acetophenone, bromo- m-nitro-, preparation of, and m-nitro-, acetate of (Evans and Brooks), A., i, 338.

2:4-dihydroxy- See Resacetoephone. o-nitroso- (Heller and Nötzel), A., i, 267.

Acetophenonecarboxylic acid, reaction of, with aniline (Meyer), A., i, 26.

Acetophenonephenylyhydrzone, α- amino- (Weil) A., i, 983.
Aceto-p-toluidide, o-iodochloride and 2-iodo- (Willgerodt and Gartner), A., i, 876.

Aceto-o- and p-toluidides, halogen derivatives (Mannino and di Donato), A., i, 826.

Acetovanillone. See Apocynin.

Acetoxyaluric acid, potassium salts (Behrend and Beer), A., i, 840.

Acetoxime, influence of acids and alkaloids on the velocity of formation (Barrett and Lapworth), T., 85.

Acetox-.. See also under the parent Substance.

Acetoxyacetic acid (acetylglycollic acid) (NeF), A., i, 7.

o-Acetoxybenzoic acid (acetylsalicylic acid), anhydride and chloride of (Farbenfabriken vorm. F. Bayer & Co.), A., i, 984.

brucine and cinchoninite salts, and their optical activity (Hilditch), T., 1391; P., 186.

Acetoxybarboxyl acids, hydrolytic fission of (Rath), A., ii, 94.

Acetoxydimethoxytriphenylcarbinyl ethyl ether (Herzig), A., i, 880.

β-Acetoxyketones, constitution of the (Blaise), A., i, 78.

Aceto-m-xylidide, 3:5:6-tri-bromo- and -chboro- (Mannino and di Donato), A., i, 826.

p-Acetoxyphenylarsonic acid and its sodium salt (Barrowcliff, Pyman, and Remfry), T., 1895.

3-Acetoxyphenyl-2-methylnaphthenazonium salts (Kehrmann and Stern), A., i, 221.

Acetoxyphenylazaphenazonium chlorides, 3- and 6- (Kehrmann and Stern), A., i, 220.

4-Acetoxysothionic acid, 2-hydroxy-, ammonium salt (v. Liebig and Heerd), A., i, 450.

2-Acetoxytolyl-5-arsonic acid and its sodium salt (Barrowcliff, Pyman, and Remfry), T., 1896.

Acetyl-.. See also Acet-, Aceto-, Acetoxy-, and under the parent Substance.

Acetyl chloridides, as agent for distinguishing between enolic and ketonic modifications (Michael and Murphy), A., i, 949.

iodo- (Aberhalden and Guggenheim), A., i, 886.

Acetylacetone, action of carbamide on (de Haan), A., i, 577.

condensation of, with o- and p-nitrobenzyl chlorides (Mech), A., i, 655.

Acetylaceton, alkaline-earth, cadmium, mercuric, and zinc derivatives (Tana- tab and Kurovski), A., i, 502.

Acetylacetoncarbamide (Majima and Kobayashi), A., i, 224.

α-Acetylisocyanic acid, ethyl ester, anilide of (Simonsen), T., 1031.

Acetyl-d-alanyl-γ-tyrosine, chloro-(Aberhalden and Hirszowski), A., i, 888.

Acetallanturic acid and its phenylhydrazone and reactions (Behrend and Beer), A., i, 841.

Acetalamino-.. See under the parent Substance.

Acetylnaphthylmethylbaptigenetin (Gorter), A., i, 98.

Acetylhydropurpurigallonecarboxylic acid (A.G. and P. M. Perkin), T., 1192; P., 149.

Acetanilidine-p-sulphonic acid, amides of (Gelmo), A., i, 409.

1-Acetylanilinobenzoxazole (Young and Dunstan), T., 1055; P., 186.

Acetanthranilic acid, 4-nitro-, reaction of, with primary amines (Bogert and Klaber), A., i, 466.

Acetantrnilic acid, brucine and cinchonine salts, and their optical activity (Hilditch), T., 1391; P., 186.

Acetylation (Law), A., i, 321.

of amino-groups, acids as accelerators in the (Smith and Orton), T., 1242; P., 132.

Acetylbenzyl cyanides. See Acetylpheynylacetanitiriles.

γ-Acetylbutyric acid and its semicarbazonide and hydrate (Haworth and Perkin), T., 588.

Acetyleatechol, o-nitro-, preparation of (Farwerke vorm. Meister, Lucius, & Bruening), A., i, 655.

Acetylechloxylose (Ryan and Ebrill), A., i, 716.

Acetylidicinesamine (Offer), A., i, 99.

Acetylidigcinimide, chloro- (Bergell and Feigl), A., i, 140.

Acetyldihydro-αβ-naphthazine (Fisher and Straus), A., i, 222.

Acetyldimethylcarbamide, cyano-, and its reactions (Haum), A., i, 253, 292.

δ-Acetyl-αα-dimethyl-n-valeric acid and its ethyl ester, oxime, and semicarbazon (Rupe and Liechtenhan), A., i, 390.
Acetyldiphenylmethane and its oxime and amino- and nitro-derivatives (Duvad), A., i, 277.

α-Acetyl-β-β-diphenylthiocarbamide and the action of caustic alkali and of heat on (Dixon and Taylor), T., 690; P., 74.

Acetylene, thermal decomposition of (Bone and Coward), T., 1197; P., 167.

action of sulphur on (Capekelle), A., i, 201; (Oechsner de Coninck), A., i, 750.

condensation product from, by means of the dark electric discharge (Jovitschitsch), A., i, 118.

condensation products, absorption of oxygen by (Losanitsch), A., i, 846.

di- and tetra-chlorides, preparation of (Tomkins), A., i, 750; (Lidholm), A., i, 933.

cooper compound, constitution of (Scheiber and Flebbe), A., i, 933.

magnesium bromide. See Magnesium-acetylene bromide metallic compounds (Makowa), A., i, 323.

estimation of phosphorus, sulphur, and silicon in (Fraenckel), A., ii, 983.

Acetylene, chloro-, mercuric derivative (Hofmann and Kirmreuther), A., i, 145.

Acetylene-carbamide and its tetra-acetyl derivative (Biltz and Horkmann), A., i, 62.

Acetylene-carboxylic acid, alkaloidal salts, and their optical activity (Hilditch), T., 706; P., 61.

Acetylenic acids, formation of 4-pyrone compounds from (Ruhemann), T., 431, 1281; P., 52, 177.

Acetyl-d-erythronic acid (Nef), A., i, 7.

4-Acetyl-1-ethyl-α-cyclohexene-3-one (Blaise and Maire), A., i, 391.

N-Acetylfumarilideoxime, cyanate (Wieland and Gmelin), A., i, 1018.

Acetylglycollic acid. See Acetoxyacetic acid.

Acetylketen and its phenylhydrzone-phenylhydrazide (Chick and Willsmore), T., 946; P., 100.

1-Acetimethylaminonanthraquinone and 4-nitro- (Farbenfabriken vorn. F. Bayer & Co.), A., i, 456.

Acetimethycarbinal (methylacetal), formation of, in the acid fermentation of wines, and its osazone and semicarbazone (Pastureau), A., ii, 136.

4-Acetyl-1-methyl-α-cyclohexene and its oxime and semicarbazone (Walach and Evans), A., i, 404.

Acetylnarcotine (Knoll & Co.), A., i, 285.

Acetylyphenylacetonitrile, o-, m-, and p-, chloro-, and 3-nitrochloro- of the p-compound (Kunckell and Flos), A., i, 890.

Acetylyphenylglycine, o-chloro-, and its ethyl ester (Schwalbe, Schulz, and Joehheim), A., i, 975.

Acetylyphenylhydrazine, conditions of formation of (Milrath), A., i, 572.

Acetylyphosphamic acid, halogen and halogen-nitro-derivatives of (Steinkopf, Benedek, Grunuff, and Kirchhoff), A., i, 962.

Acetylpiriperone, α-nitro-, preparation of (Farbwerke vorn. Meister, Lucius, & Brüning), A., i, 655.

α-Acetyl-γ-propionyl-α-butyric acid, ethyl ester, and its disemicarbazone (Blaise and Maire), A., i, 391.

Acetylsaicylic acid. See o-Acetoxybenzoic acid.

6-Acetyltoluene, 3-α-dichloro-. See o-Tolyl chloromethyl ketone, 5-chloro-. 

Acetyl-1-tryptophan, chloro- and iodo- (Abderhalden and Baumann), A., i, 932.

Acetyltyrosine, iodo-derivatives of (Abderhalden and Guggenheim), A., i, 887.

Acetyl-l-tyrosine, chloro-, derivatives of (Fischer), A., i, 544.

Acetyltirosylglycine, chloro-, and its derivatives (Fischer), A., i, 544.

Acetyltirosylglycyl-d-alanine, chloro-, methyl ester, methyl carbonate of (Fischer), A., i, 887.

Acetyl-d-valine, chloro- (Fischer and Scheiber), A., i, 957.

Acetylveratrole, amino-, preparation of (Farbenfabriken vorn. F. Bayer & Co.), A., i, 262.

Acetylveratrole, o-nitro-, preparation of (Farbwerke vorn. Meister, Lucius, & Brüning), A., i, 655.

Acetylyangonic acid and lactone (Winzheimer), A., i, 805.

Acid, C₆H₅O₃, from the action of calcium hydroxide on lactose (Kilian), A., i, 716.

C₆H₅OH, and its salts, from the action of calcium hydroxide on lactose (Kilian), A., i, 716.

C₇H₆O₈, and its esters, from the hydrolysis of ethyl 6-methyl-2-pyrones-3:5-dicarboxylate (Simonsen), T., 1027.

C₆H₅O₉, and its derivatives, from pimpinellin (Herzog and Hancu), A., i, 905.
Acid, $C_9H_4O_4$, from the oxidation of 1:1:5-trimethyl-4-cyclohexen-3-one (Crossley and Gilling), P., 130.

$C_9H_{12}O_N$, and its amide, bromide, and chloride, from biscyanomethyl-piperidium bromide (V. Braun), A., i, 608.

$C_{10}H_{15}O_2$, and its silver salt, from pinene (Henderson and Heilbron), T., 291; P., 31.

$C_{11}H_{15}O_4$, from the oxidation of 4:5-dimethoxy-2-methylbenzaldehyde (Gattermann), A., i, 34.

$C_{11}H_{15}O_4$, and its chloride, and their bromo-derivatives, from pinene (Henderson and Heilbron), T., 290; P., 31.

$C_{10}H_{15}O_2$ (two), from the glycol from camphe (Milohenski), A., i, 98.

$C_{10}H_{15}O_2Br$, from cyclohexene-α-butyr acid (Wallach, Churchhill, and Rentschler), A., i, 405.

$C_{11}H_{15}O_4$, from yangonol (Winz-heimer), A., i, 855.

$C_{12}H_{15}O_4$, and its ethyl ester, from 2-methylindole and ethyl oxalate (Angel and Marchetti), A., i, 207.

$C_{12}H_{15}O_4$, from turmeric oil (Rupe), A., i, 95.

$C_{12}H_{15}O_4$, from turmeric oil (Rupe), A., i, 95.

$C_{12}H_{15}O_2$, and its salts, from alдол and malonic acid in quinoline (Riedel), A., i, 501.

$C_{12}H_{15}O_2$, from dimethylcampholide (Kompa), A., i, 353.

$C_{12}H_{15}O_2$, ammonium and barium salts, from the action of ammonium sulphite on the lactone of 6-iodo-γ-hydroxy-3,3,4-methylenedioxypropenylvaleric acid (Bougault), A., i, 598.

$C_{12}H_{15}O_2$, and its derivatives, from rötterlin (Herrmann), A., i, 99.

$C_{12}H_{15}O_2$, from triolein ozonide (Molinari and Fenaroli), A., i, 849; (Molinari and Barosi), A., i, 850.

$C_{12}H_{15}O_2$, and its ethyl ester, from the oxidation of ethyl 2:5-diphenylpiperidone-3:5-dicarboxylic acid (Petrénko-Kritchenko and Pétroff), A., i, 565.

$C_{12}H_{15}O_2$, and its salts, from the acid, $C_{29}H_{46}O_2$ (Windaus), A., i, 728.

$C_{12}H_{15}O_2$, from cholesterol (Windaus), A., i, 728.

$C_{12}H_{15}O_2$, from olive leaves (Power and Tutin), T., 894; P., 117.

$C_{12}H_{15}O_2$, and its esters and salts, from cholesterol (Windaus), A., i, 264, 728.

Acid, $C_{26}H_{48}O_5$, and its ethyl ester, from olive bark (Power and Tutin), T., 907; P., 117.

$C_{26}H_{48}O_2$, and its salts, from the acid, $C_{26}H_{48}O_9$, and nitric and acetic acids (Windaus), A., i, 728.

$C_{26}H_{48}O_2$, and its silver salt, from onocerin (V. Hemmelmayer), A., i, 185.

$C_{26}H_{48}O_2$, from the oxidation of the ketonic acid, $C_{26}H_{48}O_3$ (Dörée and Gardner), T., 1331.

$C_{26}H_{48}O_2$, and its silver salt, from the oxidation of cholesterol (Pickard and Yates), T., 1686; P., 121.

$C_{26}H_{48}O_2$, and its salts, from the substance, $C_{26}H_{48}O_2$ (Avery and McDole), A., i, 344.

$C_{27}H_{48}O_3$, from the interaction of sulphuric acid with 1:3:5-triphenylbenzene-2:2:2'-tricarboxylic acid (Errera), A., i, 185.

$C_{27}H_{48}O_5$, $C_{27}H_{48}O_8$, and $C_{27}H_{48}O_9$, and their esters and salts, from cholesterol (Windaus), A., i, 264.

$C_{27}H_{48}O_3$, and its dimethyl ester and its oxime, from dehydrostostanedi-one (Pickard and Yates), T., 1982; P., 228.

$C_{27}H_{48}O_3$, and its ethyl ester and acetyl derivative, from the oxidation of cholesterol (Pickard and Yates), T., 1685; P., 121.

$C_{29}H_{48}O_2$, and its ethyl ester, from olive bark (Power and Tutin), T., 912; P., 118.

$C_{29}H_{48}O_2$, and its ethyl ester and salts, from olive bark (Power and Tutin), T., 906; P., 117.

$C_{29}H_{48}O_2$, and its ethyl ester and salts, from olive bark (Power and Tutin), T., 910; P., 118.

Acid amides. See Amides.

Acid anhydrides. See Anhydrides.

Acid anilides, anilo-acids, and 4-anilides (Meyer), A., i, 25.

Acid chlorides, reactions of, with thio-carbamides (Dixon and Taylor), T., 18.

liberation of carbon monoxide by heating (Bistrzycki and Landwring), A., i, 270.

Acidimetry, constitution of indicators used in (Hewitt), A., ii, 269.

Acidosis, action of various chemical substances on (Baer and Blum), A., ii, 122.

in pancreas diabetes (Allard), A., ii, 1058.

Acids, modification of the theory of (Fitzgerald and Laphworth), T., 2163; P., 274.
Acids, basicity of, as determined by their conductivities (Schmidt), A., ii, 1011.

basicity of, and formation of salts (Bruni), A., ii, 935, 1012.

and phenols, comparative experiments on the basicity and strength of (Thiel and Römer), A., i, 787.

conductivity and ionisation of, in aqueous solutions at high temperatures (Noyes, Melcher, Cooper, Eastman, and Kato), A., ii, 347.

catalytic decomposition of (Itatieżeff), A., i, 386.

and bases, diagrammatic representation of equilibria between, in solution (Henderson), A., ii, 675.

the relationship between the strength of, and their capacity to preserve neutrality (Henderson), A., ii, 268.

and pseudo-acids, comparison of, in pyridine solution (Hantzsch and Caldwell), A., ii, 21.

of unchangeable constitution, unchangeability of the colour of, during the formation of alkali salts and ions (Hantzsch, Clark, and Meyer), A., ii, 447.

of high melting point in Japanese wax (Schaal), A., i, 3.

of the formula, CHR:CH₂·CO₂H (R being phenyl more or less substituted), action of nascent hypiodous acid on (Boucault), A., i, 179, 269.

containing adjacent unsaturated groups, optically active salts of (Hilditch), T., 1388; P., 186.

use of phenolphthalein as indicator in the titration of, in presence of sulphurous acid (Pozzi-Escot), A., ii, 628.

volumetric estimation of, in air (Hensley and Bonnysy), A., ii, 734.

estimation of, in wine, in presence of alcohol and glycerol (Heduschka and Quincke), A., ii, 73.

Acids, aromatic, synthesis of (Eykmann), A., i, 794.

action of ammonia on (Korczyński), A., i, 977.

reduction of, in presence of nickel oxide (Itatieżeff and Phillipoff), A., i, 342.

substituted, synthesis of (Eykmann), A., i, 22.

dibasic, synthesis of (Blanc), A., i, 244, 245.

new determinations of the secondary ionisation constants of (McCoy), A., ii, 466; (Chandler), A., ii, 467; (Wegscheidere), A., ii, 1009.

XCIV. ii.

Acids, dibasic, esterification of, by diazomethane (Wegscheidere and Gehringer), A., i, 792.

dibasic saturated, simple ester anhydrides of (Mol), A., i, 76.

di- and poly-basic, unsymmetrical, esterification of (Wegscheidere and Gehringer), A., i, 792; (Wegscheidere; Wegscheidere, v. Rusnov, and v. Dubrav), A., i, 793; (Wegscheidere and Strauch), A., i, 794.

polybasic, ferrous and ferric double salts of (Scholz), A., i, 603.

fatty, from mummies (Schmidt), A., i, 878.

acidification and distillation of (Dubovitz), A., ii, 991.

oxidation of (Friedmann; Dakin), A., ii, 719; (Knoop), A., ii, 720.

action of metallic magnesium on (Fenton and Sisson), A., i, 243.

of protein putrefaction (Neuberg and Rosenberg), A., i, 116.

hydrates of (Tsakalotos), A., i, 598.

according to measurements of the viscosity of their solutions (Tsakalotos), A., i, 498.

mode of oxidation of phenyl derivatives of, in the organism (Dakin), A., ii, 965.

oxidation of phenyl derivatives of, by the organism and by hydrogen peroxide (Dakin), A., ii, 720.

constitution of glucinum salts of (Glasmann and Novicky), A., i, 120.

preparation of isobornyl esters of (Chemische Fabrik von Heyden), A., i, 351, 809.

fatty saturated, oxidation of ammonium salts of, with hydrogen peroxide (Dakin), A., i, 118.

fatty unsaturated, addition of hydrogen iodide to (Farbenfabriken vorm. F. Bayer & Co.), A., i, 123.

higher fatty, preparation of diacyl glycerides of (Ulzer, Batik, and Sommer), A., i, 310.

in liver after removal (Leathes), A., ii, 1054.

azo-colouring matters from the aminoanilides of (Sulzberger), A., i, 226.

higher fatty brominated, alkaline-earth salts of (Farbenfabriken vorm. F. Bayer & Co.), A., i, 122.
Acids, normal fatty, esterification constants of (Sudborough and Gittens), T., 210; P., 14.

meltlng points of anilides, p-toluidides, and a-naphthalides of (Robertson), T., 1035; P., 120.

fixed and volatile, new method of estimating, in wine (Pozzi-Escot), A., ii, 904.

free, detection of, in organic liquids (Repiton), A., ii, 781.

inorganic complex (Miolati and Pizzigelli), A., ii, 595.

mineral, relative efficiencies of, as deduced from their conductivities and hydrolytic activities (Armstrong and Wheeler), A., ii, 815.

detection and estimation of, in red wines (Astre), A., ii, 892.

organic, affinity constants of, determined with the help of indicators (Salm), A., ii, 677.

reactions of, with mercuric chloride (Oechnser de Coninck and Dautry), A., i, 392.

colour reactions of, with phenols (Fenton and Baaer), A., ii, 438.

salts, the electrolytic chlorination of (Inglis and Wootton), T., 1592; P., 174.

metallic salts (Werner, Jovanovits, Aschkinasy, and Posselt), A., i, 935.

organic non-volatile, estimation of, in tobacco (Toth), A., ii, 288.

organic volatile, estimation of, in tobacco (Toth), A., ii, 330.

saturated, and their esters, electrolytic production of, from the corresponding unsaturated compounds (Boehninger & Sohne), A., i, 122.

saturated or unsaturated, alkaloidal salts, relation between optical activity and unsaturation in (Hilditch), T., 700; P., 61.

tautomeric, and salts, reactions of, with diazomethane and alkyl haloids (Ackee, Johnson, Brunel, Shadinger, and Nirdlinger), A., i, 919.

unsaturated, action of nascent hypoiodous acid on (Bougault), A., i, 179, 269, 597, 791, 983.

catalytic reduction of (Paal and Gerum), A., i, 599.

addition of mercaptans to (Posner and Baumgartt), A., i, 21.

of the benzene series, relation between the absorption spectra and chemical constitution of (Baly and Schaefer), T., 1808; P., 207.

Acids, aβ-unsaturated, behaviour of, when perfused through the liver (Friedmann), A., ii, 719.

weak, hydrolysis of salts of, and its variation with temperature (Lunden), A., ii, 164.

Acetine, oxidation products of (Schulze), A., i, 560.

Acetinone, action of, on nerve fibres (Waller), A., ii, 55.

Acridine, new synthesis of (Borsche, Tiedke, and Rottsieper), A., i, 652.

Acridines, complex, synthesis of (Austin), T., 1769; P., 200.

Acridone, conversion of, into phenyl-acridine derivatives (Ullmann, Bader, and Labhardt), A., i, 52.

Acryltropeine and its picrate (Wolffenstein and Rolle), A., i, 282.

Actinium, relative activity of emanation and active deposit from (Bronson), A., ii, 792.

electrical charge of the active deposit of (Russ), A., ii, 556.

distribution in electric fields of the active deposits of (Russ), A., ii, 552.

emanation and thorium emanation, condensation of (Kingshita), A., ii, 652.

β-rays of (Hahn and Meitner), A., ii, 1007.

Actinium C, a new short-lived product of actinium (Hahn and Meitner), A., ii, 920.

Actinolite, from Iron Mine Hill, Rhode Island (Johnson and Warren), A., ii, 293.

Acyaminocompounds, the mechanism of bromination of (Ackee, Johnson, and Nirdlinger), A., ii, 29.

Acybenzoic acids, preparation of, from phthalic anhydride, hydrocarbons, and aluminium chloride (Heller), A., i, 648.
Acylcarbamides, organic salts of (Baum), A., i, 252.

Acyl groups, capacity of, for migration in the molecules of organic compounds (Auwers and Dannehl), A., ii, 458.

Acylhydroxyamines, labile isomerism among (Titherley), P., 78.

Acylisocyanilamides, labile isomerism among (Titherley), P., 78.

Acylisocyclic anhydrides, preparation of (Farbenfabriken Vorm. F. Bayer & Co.), A., i, 934.

Additivity and residual affinity, connexion between (Peters), A., ii, 937.

Address, presidential (Ramsay), T., 774; P., 87.

Adipic acid, preparation of (Boivault and Locquin), A., i, 393.

preparation of, from cyclohexanol (Mannig and Hanau), A., i, 245.

Adipic acid, methyl and ethyl esters, syntheses by means of (Boivault and Locquin), A., i, 172.

Adipic acid, \(3,3\)-diamino-, synthesis of, and its dibenzoyl derivative (Sorensen and Andersen), A., i, 650.

\(meso-aa\)-dihydroxy-, preparation of, and action of heat on, and its methyl ester, amide, anilide, and lactone-lactide (Le Sueur), T., 716; P., 70.

\(\text{trans-}aa\)-dihydroxy-, preparation of, and action of heat on, and resolution of, and its amide, anilide, and dilactone (Le Sueur), T., 719; P., 70.

Adipic semialdehyde. See \[5\)-Aldehydovaleric acid.

Adrenaline (suprarenine), chemical changes in, produced by enzymes (Neuberg), A., ii, 380.

action of free alkalis on (Grubler), A., i, 204.

action of tyrosinase on (Abderhalden and Guggenheim), A., i, 1030.

physiological action of (Kretschmer), A., ii, 55.

the relationship of the thyroid gland to the physiological action of (Pick and Pineles), A., ii, 875.

physiological action of optical isomers of (Cushny), A., ii, 720.

Adrenaline series, preparation of bases of the (Chemische Fabrik auf Aktien vorm. E. Schering), A., i, 1004.

Adsorption and occlusion; nature of the so-called solid phase (Travers; Freundlich), A., ii, 18.

and the behaviour of casein in acid solutions (L. L. and D. D. Van Slyke), A., i, 375; (Robertson), A., ii, 89.

Adsorption, theory of (Robertson), A., ii, 518.

negative (Tezner and Roska), A., ii, 810; (Hertzog), A., ii, 928.

Adsorption analysis, apparatus for (Wilslicenus), A., ii, 262.

Adsorption compounds (Jorgensen), A., ii, 261.

Adsorption phenomena of inorganic salts (Wohlers), A., ii, 819.

Aeschnite, chemical constitution of a specimen of (Tschernek), A., ii, 399.

Affinity, chemical:

Affinity of certain alkaloids for hydrochloric acid (Veley), T., 2114; P., 234.

residual, and additivity, connexion between (Peters), A., ii, 937.

of the coumarins and thio-coumarins as shown by their additive compounds (Clayton), T., 524; P., 26.

Affinity constants of organic acids determined with the help of indicators (Salm), A., ii, 677.

of bases as determined by the aid of methyl-orange (Veley), T., 652, 2122; P., 50, 238.

of several urazoles (Acree and Shadinger), A., i, 224.

Affinity values of tropine and its derivatives (Veley), P., 280.

Mass action, lecture experiment to demonstrate the law of (Abel), A., ii, 934.

does the law of, hold for the silent electrical discharge? (Le Blanc and Davies), A., ii, 653; (Pohl; Le Blanc), A., ii, 819.

Mass law and non-miscibility (Bancroft), A., ii, 161.

Dynamic isomerism (British Association Reports), A., i, 351.

studies of (Lowry and Magson), T., 107, 119.

benzyl sulphoxide as a possible example of (Smythe), P., 285.

Chemical change, homogeneous, in a gas, measurement of a (Clarke and Chapman), T., 1638; P., 190.

Chemical dynamics of the reactions between sodium thiostate and organic halogen compounds (Slator and Twiss), P., 286.

Chemical equilibria, application of the new arrangement of the Koning spectrophotometer to the determination of (Hildebrand), A., ii, 616.

between acids and bases in solution, diagrammatic representation of (Henderson), A., ii, 675.
INDEX OF SUBJECTS.

Affinity, chemical:—

Chemical equilibria, hydrocarbon, calculation of (v. Wartenberg), A., ii, 26, 676.

Chemical equilibrium between carbon dioxide, sodium hydrogen carbonate, sodium phosphate, and disodium phosphate at body temperature (Henderson and Black), A., ii, 467.

the system, copper oxide, sulphur trioxide, and water at 25° (Bell and Tadek), A., ii, 382.

conditions of, in the systems, ferric chloride, potassium ferrocyanide, water (Volschin), A., ii, 468.

the system, mercuric chloride, ammonium chloride, and water at 30° (Meerburg), A., ii, 676.

in the system, silver nitrate and pyridine (Kahlenberg and Brewey), A., ii, 469.

Equilibrium constant, influence of the solvent on the (Pissarjewsky and Levits), A., ii, 570.

Equilibrium relations of chromates in solution (Sherrill, Eaton, Merrill, and Russell), A., ii, 92.

of the reaction between chloric and hydrochloric acids; a reaction of the eighth order (Luther and MacDougall), A., ii, 361.

of the transformations of radioactive compounds (Guye), A., ii, 451.

of successive reactions (Jableczynski), A., ii, 935.

of the sulphonation reaction (Martinsen), A., ii, 572.

Reactivity of undissociated electrolytes (Wegscheider), A., ii, 265.

Chemical reaction, reversible, dynamic theory of a (Cohen and Strenger), A., ii, 824, 934; (Smiths and Wibaut), 824, 934.

Chemical reactions, mechanism of; intermediate products and intermediate structures (Tiffeneau), A., i, 117.

in a magnetic field (Berndt), A., ii, 766.

Transition concentrations (Wirth), A., ii, 570.

Catalysis (Stieglitz), A., ii, 29, 472; (Acree, Johnson, and Niedlinger), A., ii, 29; (Acree), A., ii, 169, 472, 1022; (McCracken), A., ii, 572; (Schlesinger), A., ii, 680.

Affinity, chemical:—

Catalysis, stereochemistry of (Bredig and Fajans), A., ii, 268.

in heterogeneous systems (Jableczynski), A., ii, 680.

examination of the conception of hydrogen ions in (Leipworth), T., 2187; P., 275.

of esters and of imino-esters by acids (Stieglitz), A., ii, 167.

of imino-esters (Derby), A., i, 119; (Stieglitz), A., ii, 168.

Catalytic actions of colloidal metals of the platinum group (Paal and Gerum; Paal and Roth), A., i, 599.

Catalytic ester exchanges (Kremann), A., i, 120; ii, 1021; (Stritar and Fanto), A., ii, 677, 1021.

Catalytic pulsations, excitation and regulation of, by means of an electric current (Bredig and Wilke), A., ii, 679.

Catalytic reactions and photochemical equilibria (Vanzetti), A., ii, 915.

at high temperatures and pressures (Ipatieff), A., ii, 266, 332, 347, 386; (Ipatieff, Jakowleff, and Rakitin), A., i, 330; (Ipatieff and Philipoff), A., i, 342.

induced by enzymes (Acree), A., ii, 1022.

of oxidation and reduction of unsaturated organic compounds (Fokin), A., i, 311.

of sunlight (Neuberg), A., ii, 915.

Dissociation as measured by lowering of freezing point and by electrical conductivity; bearing on the hydrate theory (Jones and Pearce), A., ii, 19.

by absorbing substances of the compounds formed by basic and acidic dyes (Felet-Jolivet), A., ii, 18.

of a compound in a state of equilibrium, and a thermodynamic relation necessary to the validity of the law of constant proportions (Ruér), A., ii, 819.

variation of the degree of, of certain electrolytes with temperature (Campetti), A., ii, 1010.

doUBLE, of quaternary ammonium compounds (v. Braun), A., i, 627.

of the polyiodides of the alkali metals and ammonium radicles (Dawson), T., 1308; P., 181.

Dissociation equilibria, heterogeneous, an apparent exception to the theory of (Abegg), A., ii, 157.
Affinity, chemical:

Dissociation pressures of some metallic carbonates and hydr-oxides (Johnston), A., ii, 358; (Schottky), A., ii, 1016.
of certain oxides of cobalt, copper, antimony, and nickel (Foote and Smith), A., ii, 847.
of ferric oxide (Walden), A., ii, 852.
of solid and liquid substances, simple apparatus for demonstrating (V. Zawidzki), A., ii, 261.

Energy, free, change of, accompanying the formation of some fused salts of the heavy metals (Lorenz and Fox), A., ii, 656.
changes attending the formation of certain carbonates and hydr-oxides (Johnston), A., ii, 812.
internal, of dissolved substances (Schukareff), A., ii, 462.
potential, of the elements (Rankin), A., ii, 680.

Enzyme action, studies on (Armstrong and Glover), A., i, 712; (H. E. and E. F. Armstrong and Horton), A., i, 745.
discussion on the mechanism of (Philochie), A., i, 712.

Hydrolysis, theory of (Fanto and Stritar), A., i, 499; (Stieglitz; Acree), A., ii, 472.
as illustrated by heats of neutralisation (Veley), A., ii, 813.
hydrolation, and hydronation as determinants of the properties of aqueous solutions (Armstrong), A., ii, 814.
influence of salts on, and the determination of hydration values (Armstrong and Grothers), A., ii, 816.

of the glycerides, theory of the (Wegscheider), A., i, 499; ii, 165.
during ester exchanges in homoge- nous systems (Stritar and Fanto), A., ii, 677, 1021; (Kremann), A., ii, 1021.
of salts (Rosenstiehl), A., ii, 164.
in solution; lecture experiment (Vanzetti), A., ii, 805.
electrometric determination of the (Denham), T., 41.
of the salts of weak acids and bases and its variation with temperature (Lunden), A., ii, 164.

Hydrolytic fission of acetoxycarb-oxylc acids (Rath), A., ii, 94.

Velocity of absorption of gaseous by solid substances (Hantzsch and Wiegner), A., ii, 158.
Index of Subjects.

Agglutination and coagulation (Arrenius), A., ii, 822.

Agglutinins, electrical charge of (Field and Teague), A., ii, 118.

Agglomerin (Mestrezat), A., ii, 708.

Agnotobenzaldehyde (Abderhalden), A., ii, 310.

Albumin, constitution of (Heller and Soullis), A., i, 208.

Albumose, action of thorium nitrate and of uranyl nitrate on (Szilárd), A., i, 68.

Albumose in blood (Abderhalden), A., ii, 605.

amount of, in blood (Freund), A., ii, 117, 512; (Abderhalden), A., ii, 305.

Albumoses, peptones, and glycine, isolation of, from dilute aqueous solutions (Siegfried), A., i, 234.

preparation of stable soluble compounds of hexamethyleneetramine silver nitrate with (Busch), A., i, 712.

Alcaptonuria, metabolism in (Abderhalden and Bloch), A., ii, 64.

Alcohol. See Ethyl alcohol.

Alcohol, C,H,O, and its acetate and phenylurethane, from cyclobutylidimethylcarbinol (Kijner), A., i, 550.

C,H,O, methyl ether, from estragole methylidohydridin (Daupresne), A., i, 20.

C,H,O, and its phenylurethane and acid phthalic ester, from pineine (Henderson and Heilbron), T., 292; P., 31.

C,H,O, secondary, from 5-pinene (Smirnoff), A., i, 278.

C,H,O, from the reduction of geranil (Enklaar), A., i, 664.

C,H,O, from the action of magnesium methyl iodide on methyl methoxytoluate (Behal and Tiffin), A., i, 630.

C,H,O, and its acetyl derivative, from heerabol myrrh (v. Friedrichs), A., i, 97.

C,H,O, (or C,H,O), and its acetyl derivative, from Grindelia resin (Power and Tutin), A., ii, 526.

C,H,O, from olive bark (Power and Tutin), T., 910; P., 118.

Alcoholic fermentation. See Fermentation.

Alcoholometry, gravimetric (Blondeau), A., ii, 990.

Alcohols, index of refraction of mixtures of, with water (Doroschewsky and Dvorschantschik), A., 'ii, 241, 785.

decomposition of, in presence of metallic oxides (Ipatieff), A., ii, 472.

decomposition of, under the catalytic influence of charcoal (braise) (Lemoine), A., i, 585.

Air. See Atmospheric air.

Alanine, synthesis of (Zelinsky and Stadnikoff), A., i, 607.

elimination of, by the urine (Brugsch and Hirsch), A., ii, 611.

\textit{d}-Alanine derivatives, synthesis of (Abderhalden and Hirszowski), A., i, 887.

\textit{\beta}-Alanine, \textit{\alpha}-bromo-, hydrobromide of (Gabriel), A., i, 181.

Alanine anhydride, nitration and acetylation of (Franchimont and Friedmann), A., i, 509.

Alanyl-\textit{\beta}-amino-butyric acid and its copper salt (Kay), A., i, 774.

\textit{d}-Alanyldiglycylglycine (Abderhalden and Hirszowski), A., i, 888.

\textit{dl}-Alanyldiglycylglycine (Fischer), A., i, 325.

Alanylglycinimide and its hydrochloride (Bergell and Feigl), A., i, 141.

\textit{dl}-Alanylglycylglycine (Fischer), A., i, 325.

\textit{dl}-Alanylt-tryptophan anhydride (Abderhalden and Baumann), A., i, 982.

\textit{dl}-Alanylt-tyrosine and 3:5-diaido-. (Abderhalden and Hirszowski), A., i, 888.

\textit{dl}-Alanylt-tyrosine, 3:5-diaido-. (Abderhalden and Guggenheim), A., i, 887.

\textit{dl}-Alanylt-valine and its anhydride (Fischer and Scheibler), A., i, 958.

Albite from Greenland (Dreyer and Goldschmidt), A., ii, 116.

Albumin, synthesis of living (Latham), A., i, 709.

diffusion of, into gelatin jellies (Möllhausen), A., ii, 670.

vanillin-hydrochloric acid as a test for (Rosenthaler), A., ii, 76.

estimation of, in urine by Esbach's method (van der Harst), A., ii, 643.
Alcohols, catalytic dehydration of, by calcium sulphate and by aluminium silicate (Senderens), A., i, 495.
quantitative researches on the exhalation of (Pohl), A., ii, 1056.
and wines, action of, on frogs (Nazari), A., ii, 973.

Alcohols of the allyl series, use of magnesium in place of zinc in the synthesis of (Javorsky), A., i, 755.
aromatic, new reactions of (Fosse), A., i, 85.
dicyclic, with bridged linkings, formation of (Rabe and Jahn), A., i, 553.
diterary, from phenanthraquinone (Zincke and Tropp), A., i, 786.
fatty, contact oxidation of (Oloff), A., i, 306.
hydroaromatic, preparation of alkyl-oxoacyt derivatives of (Farbenfabriken vorm. F. Bayer & Co.),
A., i, 429.
multivalent, complex compounds of, with metallic salts (Grün and Bockisch), A., i, 934.
olefinic, formation of (Gry), A., i, 307.
primary, action of metallic oxides on (Sabanier and Maille), A., i, 594, 715.
transformation of, into aldehydes and hydrogen (Bouveault), A., i, 117.
three new primary, from the condensation of sodium benzylxoxide with propyl, butyl, and isomyl alcohols (Guerbet), A., i, 655.
See also Amino-alcohols, Benzoyl-alkylamino-alcohols, Chlorohydrins, aa-Dialkyl-ß-keto-alcohols, Iodo-
yhydrins, and Keto-alcohols.

Aldebaranium (v. Welsbach), A., ii, 591; (Urbain), A., ii, 849.

Aldehyde. See Acetaldehyde.

Aldehyde, C<sub>8</sub>H<sub>12</sub>O, and its oxime and semicarbazono, from cyclobutylidine-methylcarbinol (Kinner), A., i, 531.
C<sub>11</sub>H<sub>16</sub>O<sub>3</sub> and its derivatives, from ary-tetrahydro-α-naphthol (Gattermann), A., i, 30.

Aldehyde-acids, naphtharsorcinol as a reagent for (Mandel and Neuberg), A., ii, 993.

Aldehydephenylhydrzones, action of nitrogen peroxide on (Ciussa and Pestalozza), A., i, 833.

Aldehydes and quinones, preparation of (Lang), A., i, 350.
formation of, during acetic fermentation (Farnsteiner), A., ii, 318.

Aldehydes, formation of, under the influence of yeasts (Trillat and Saiton), A., ii, 615, 722.
formation of, from their acids (Mering), A., i, 654; (Staudinger), A., i, 654.
transformation of α-hydroxy-acids into (Guerbet), A., i, 123.
formation of, from primary alcohols (Bouveault), A., i, 117.
formation of, from amides of α-bromo-fatty acids (Mossler), A., i, 133.
preparation of, from aromatic compounds containing the group C,H<sub>3</sub> by oxidation with ozone (Spurge),
A., i, 423.
condensation of acetomediarboxylic esters with, under the influence of ammonia and amines (Petersen-Kritschkenko and Petroff), A., i, 564.
action of a mixture of mercury diethyl and sodium on (Schorigin), A., i, 881.
condensation of, with β-phenylenediamine, β-naphthylamine, and β-naphthylhydrzone (rothenfusser),
A., i, 52.
action of phosphorus pentachloride and of thionyl chloride on (Hoering and Baum), A., i, 528; (Schmidt), A., i, 654.
condensation of, with substituted rhodanic acids (Andreas), A., i, 653.

4:4'-Bismethylhydrizinodiphenylmethane for characterising (v. Braus), A., i, 700.
estimation of, by the spectroscope (Brutlants), A., ii, 547.

Aldehydes, aromatic, synthesis of (Gattermann), A., i, 28.
condensation of, with aminoaldehydes (Puxeddu), A., i, 286.
condensation of, with cyclic ketones (Wallach, Mallison, and Martius), A., i, 424.
action of potassium cyanide on (Ekectrantz and Ahlqvist), A., i, 992.
formation of bases by the condensation of, with phenyl-p-phenylenediamine, and their hydro-
chlorides (Moore and Woodbridge), A., i, 686.
colour reactions of, with phenols and various cyclic, heterocyclic, and open-chain compounds (Fleig),
A., ii, 1078.
cyclic, method of preparing (Savrion), A., i, 188.
INDEX OF SUBJECTS.

Alkali nitrates, double, with nitrates of the cerium metals (Wyrouboff), A., ii, 385.

protopoxides, heat of formation of (Ren-gade), A., ii, 155.

silicates (Jordis), A., ii, 103, 492.

polysulphides, action of methyl sulphate on (Strecker), A., i, 386.

thioantimonates (Donk), A., ii, 763, 859.

trithionates and tetra thionates (Mackenzie and Marshall), T., 1726; P., 199.

Alkaline-earth carbonates and alkali carbonates, thermochemical data of (de Forcrand), A., ii, 256.

influence of addition of chloride on the reaction between carbon, nitrogen, and (Kühling and Berkhold), A., i, 143.

cyanoxydes and cyanamides (Badische Anilin- & Soda-Fabrik), A., i, 964.

iodides, specific gravities of (Baxter and Brink), A., ii, 377.

preparation of colloidal amorphous forms of crystalline and soluble salts of (v. Weimarn), A., ii, 842.

oxides, crystallisation of, from their nitrates (Brügelmann), A., ii, 842.

salts, anomalous modifications of the band spectra of, in the magnetic field (Dufour), A., ii, 138.

colloidal and gelatinous (Neuberg and Rewald), A., ii, 495.

Alkaline earths, alloys of, with mercury (Smith), A., ii, 38.

estimation of, in manures and soils (Förster), A., ii, 1072.

estimation of, in waters (Blacher and Jacoby), A., ii, 897.

Alkalinity, determination of, by electrochemical means (Lange), A., ii, 534.

Alkalis, action of, on sodium alkyl thiosulphates (Price and Twiss), T., 1395, 1403; P., 179, 185.

action of, on sodium ethyl thiosulphate (Gutmann), A., i, 497.

compounds of, with mercuric cyanide (Hoffmann and Wagner), A., i, 514.

separation of magnesium from the (Gooch and Eddy), A., ii, 632.

Alkaloid, C_{19}H_{17}O_{2}N, and its additive salts, from Chinese Corydalis tubers (Makoshi), A., i, 825.

Alkaloids, affinity of certain, for hydrochloric acid (Veley), T., 2114; P., 234.

Alkaloids, cinchona. See Cinchona.

of Corydalis. See Corydalis.

of Nigella (Keller), A., i, 283.

Strychnos. See Strychnos.

reaction of, with sodium hypobromite (Dehn and Scott), A., i, 780.

addition of bromoacetonitrile to (v. Braun), A., i, 676.

and artificial antitoxins, supposed antitoxides to (Dorlencourt), A., ii, 721.

and iron, double salts of (Scholtz), A., i, 202.

reactions of (Reichard), A., ii, 643.

estimation of, by means of picrolic acid (Matthes and Rammstedt), A., ii, 75.

estimation of total, in cinchona barks (Cohen), A., ii, 996.

estimation of total, in coca leaves (De Jong), A., ii, 440; (Greshoff), A., ii, 441.

Alkyl argenticyanides, heats of combustion of (Gullemard), A., i, 719.

haloids, interaction of, with aluminium (Spencer and Wallace), T., 1829; P., 194.

action of, amorphous arsenic on (Auger), A., i, 13.

direct interaction of, with magnesium (Spencer and Crewdson), T., 1821; P., 194.

iodides, effect of heat on (Kahan), T., 132.

nitrates, reduction of, to nitrites in alkaline solution (Gutmann), A., i, 597.

sodium compounds and syntheses therewith (Schorgin), A., i, 881, 886.

sodium thiosulphates, action of alkalis on (Price and Twiss), T., 1395, 1403; P., 179, 185.

Alkylamines, formation of, in nerve degeneration (Bauer), A., ii, 717.

Alkylaminocetals (Paal and van Gember), A., i, 511.

Alkylaminoalkyl p-aminobenzoates, preparation of (Mercck), A., i, 266.

benzoates, preparation of (Farberweke vom. Meister, Lucius, & Brön-ing), A., i, 266.

2-Alkylanolhydrines (Michaelis, Mieelecke, and Lütze), A., i, 61.

β-Alkylicnamic acids (Rupe and Busholt), A., i, 23; Schroeter and Buchholz), A., i, 109.

Alkylene glycol-chlorohydrin ethers. See Glycol-chlorohydrin ethers.

Alkylyguanidine salts (Majima), A., i, 223.
Alkylguanidines, condensation of, with ethyl acetooacetate (Majima and Kobayashi), A., ii, 223.

1-Alkylcyclohexan-2-one-1-carboxylic acids, esters, influence of the alkyl groups on the synthesis and degradation of (Kötz, Bieber, Hess, and Schwarz), A., i, 24.

N-Alkylketoximes (Scheibler), A., i, 768; (Scheiber and Brandt), A., i, 764.

Alkyloxy-groups, displacement of, in the benzene nucleus by hydrogen (Semmler), A., i, 557.

4-Alkylquinolines (Blaise and Maire), A., i, 566.

Alkylsulphine perbromides and periodides (Tinkler), T., 1611; P., 191.

2-Alkylthiobenzoic acids (alkylthiosaliclyclic acids), preparation of (Fandwerke vorm. Meister, Lucius, & Brünning), A., i, 797.

Alkyl vinyl ketones, reactions of (Maire), A., i, 247; (Blaise and Maire), A., i, 390.

fixation of amines on the ethylenic linking of (Blaise and Maire), A., i, 398.

fixation of aromatic amines on (Blaise and Maire), A., i, 566.

action of nitrogen-containing reagents on the carbonyl group of (Maire), A., i, 290.

Allantoin, the importance of, in uric acid metabolism (Wiechowski), A., ii, 119.

Allopiane, ratio of alumina and silica in (Stremme), A., ii, 1041.

Alloporphyrin and its salts and anhydride (Willstätter and Pfannenstiel), A., i, 198.

Alloxanyltetramethyl-m-phenylenediamine (Sachs and Appenzeller), A., i, 187.

Alloys of metals which form nitrides, preparation of (Beck), A., ii, 587.

electrical conductivity of, and their temperature coefficients (Guertler), A., ii, 557; (Rudolf), A., ii, 923.

thermal diagrams and microscopy of (Friedrich), A., ii, 1045.

binary, correction of the ideal melting-point curves of (Mazzotto), A., ii, 660.

method for the measurement of rate of change in solid (Bengough), P., 145.

hardness of (Saposnikoff), A., ii, 600.

optical method for determining the relative hardness of contiguous structural elements of (Cigler), A., ii, 593.

Alloys, interaction of, with mercury (Mallet), A., ii, 187.

qualitative study of (Giolitti), A., ii, 945.

analysis of (Namias), A., ii, 326; (Schürmann and Schaffeberg), A., ii, 537; (Schürmann and Arnold), A., ii, 898.

planimetric analysis of (Bengough), P., 146; (Huntington and Desch), A., ii, 846.

estimation of lead in (Elborne and Warren), A., ii, 735.

Allyl alcohol, triiodo-, and its acetate (Lespieau), A., i, 496.

Allylamine, action of nitrous acid on (Henry), A., i, 81.

Allylaminocetal and its derivatives (Paal and van Gember), A., i, 511.

Allylazomide and its dibromide and diazoamino-compound (Forster and Fierz), T., 1174; P., 143.

1-v-Allyl-3,4-catechol methylene ether. See v-Safrole.

3-v-Allyl-o-cresol and its methyl ether (Béhal and Tiffeneau), A., i, 630.

Allylhippuric acid (Sörensen), A., i, 981.

3-Allylhydantoin (Bailey and Randolph), A., i, 741.

a-Allylinsphthalene and its iodohydrin (Tiffeneau and Dau del), A., i, 972.

Allylthio carbamide, reaction of, with acetyl chloride (Dixon and Taylor), T., 22.

Allylthiocarbimide, action of, on ethyl sodiomalate (Rühemann), T., 625.

Almond, globulin from the. See under Globulin.

Almond extracts, colorimetric estimation of benzaldehyde in (Woodman and Lyford), A., ii, 1079.

Almond tree, gum of the (Huerre), A., i, 606.

Alnus glutinosa, alcohols and resinous acids in the varnish from the leaves of (H. and A. v. Euler), A., i, 39.

Aloesol, a complex phenol from aloes, and tetracloro- and its acetyl derivative (Léger), A., i, 40, 980.

Aloisite, a new hydroxilicate from the tufa of Fort Portal, Uganda (Colomba), A., ii, 956.

Alumina. See Aluminium oxide.

Aluminium, the chief inorganic element in a proteaceous tree, and the occurrence of aluminium succinate in trees of this species (Smith), A., ii, 855.

in the potential series (van Deventer and van Lumme1), A., ii, 12, 558; (van Laar), A., ii, 248, 558.
INDEX OF SUBJECTS. 1235

Aluminium, interaction of, with alkyl haloids (SPENCER and WALLACE), T., 1899; P., 194.
finely powdered, interaction of, with carbon (WESTON and ELLIS), A., ii, 849.
action of, on silica and boron trioxide (WESTON and ELLIS), A., ii, 885.

Aluminium alloys (Gwyer), A., ii, 234.
with calcium (Donski), A., ii, 279.
with copper, electrolytic corrosion of (ROWLAND), A., ii, 381.
with silicon (Fraenkel), A., ii, 592.
with tin, hardness of (SAPOSHKOFF), A., ii, 600.
with zinc, hardness of (Saposhnikoff), A., ii, 284.

Aluminium compounds with manganese (Hindrichs), A., ii, 857.

Aluminium boride (Biltz, A., ii, 763.
bromide, preparation of, and its latent heat of fusion (Kabukoff), A., ii, 499.
carbide (Weston and Ellis), A., ii, 849.
formation of (Pring), T., 2103; P., 240.
chloride, new catalytic effect of (Bøttker), A., i, 621.
hydroxide, amphoteric character of (Wood), T., 417; P., 15.
colloidal, coagulation of, by electrolytes (Kawamura), A., ii, 949.
mercuri-iodide (Duboin), A., ii, 598.
oxide (alumina), fibre-like, and its surface actions (Wislicenus), A., ii, 261.
catalytic power of (senderens), A., ii, 166.
and silica, precipitation of gelatinous mixtures of, and their relation to allophane, halloysite, and montmorillonite (Stremme), A., ii, 1041.
iron, and phosphoric acid, estimation of, in presence of each other (Cooksey), A., ii, 297.
and silica, estimation of, in iron ores (Timby), A., ii, 533.
iron phosphates, utilisation of native (Schröder), A., ii, 500.
silicates (Uffers), A., ii, 592.
kathon silicates (Weiβer), A., ii, 697.
vandadium silicidos (Manchot and Fischer), A., ii, 46.
sulphate, compound of, with guanidine sulphate (Ferraboschi), A., i, 720.
sulphide and iron sulphide, probable existence of a compound of (Ditz), A., ii, 111.

Aluminium titanide (Manchot and Richter), A., ii, 40.
Aluminium and iron groups, qualitative analysis of the (Noyes, Bray, and Speark), A., ii, 538.

Alveolar air, tension of carbon dioxide in, during chloroform narcosis (Collingwood and Buswell), A., ii, 49.
tension of carbon dioxide in, during exercise (Collingwood and Buswell), A., ii, 49.

Allypine, colour test for (Lemaire), A., ii, 784.

Amalgams. See Mercury alloys.

Amanitin Phalloides, poisons of (Abel and Ford), A., ii, 1051.

Amarine, resolution of the iminazole ring in (Fischer and Prats), A., i, 219.

Amitase, occurrence and action of (Effront), A., i, 491.

Amides, molecular complexity of, in various solvents (Meldrum and Turner), T., 876; P., 98.
influence of, on protein metabolism (Friedländer), A., ii, 514.
of higher fatty acids, compounds of, with chloral (Sulzberger), A., i, 600.
acid, action of beer yeast on (Effront), A., i, 491.
value of, in Carnivora (Völtz and Yakua), A., ii, 207.
N-methylolcompounds of (Einhorn, Feibelmann, Göttler, Hammer, and Spröngert), A., i, 608.
aromatic, of the higher fatty acids, interaction of diazo-salts with (Sulzberger), A., i, 483.
diphenylated acid, preparation of, by the action of diphenylcarbamid on acids (Herzog und Hänch), A., i, 268.
halogenated acid, action of phosphorus pentachloride on (Steinkopf, Benedek, Grünupp, and Kirchhoff), A., i, 961.
plant, nutritive value of (Schulze), A., ii, 260.

Amides, thio-. See Thioamides.

Amidines, the chemistry of the (Young and Dunstan), T., 1052; P., 130.

Amine, C₈H₁₇N, and its hydrochloride and platinichloride, from pinene (Henderson and Heilbron), T., 293; P., 31.
C₁₈H₂₈OₓNₓ, from the reduction of methylvanillinoxime (Rühheimer and Schön), A., i, 154.

Amines, reaction of, with alkyl vinyl ketones (Blaise and Maire), A., i, 398.
Amines, action of, on cinnamylideneacetic acid and its methyl ester (RIEDEL), A., i, 536.
interaction of, with 2:3:5-trinitro-4-acetylaminothiphenol (MELDOLA and HAY), T., 1659; P., 197.
combination of, with benzoic acid (V. LIEBIG), A., i, 616.
and ammonia, separation of, by means of boiling absolute alcohol (BERTHEAUME), A., ii, 742.

Amines, aromatic, reaction of, with glyoxal sodium hydrogen sulphite (HINSBERG), A., i, 453.
action of halogens on, and their use in the synthesis of certain dyes (OSTROGOVICH and SILBERMANN), A., i, 373.
reaction of, with sodium hypobromite (DEHN and SCOTT), A., i, 780.
reduction of, in presence of nickel oxide (IPATIEFF), A., i, 332.
fixation of, on alkyl vinyl ketones (BLAISE and MAIRE), A., i, 566.
aromatic primary, condensation of chloral with (WHEELER, DICKSON, JORDAN, and MILLER), A., i, 332.
phenyl derivatives of (GOLDBERG and SISSEOFF), A., i, 17.
aromatic secondary, action of formaldehyde on (V. BRAUN), A., i, 684.
aromatic tertiary, addition of bromoacetoniitrile to (V. BRAUN), A., i, 676.
fatty, affinity constants of, as determined by the aid of methyl-orange (VELEY), T., 661; P., 50.
primary, reaction of, with 4-nitroacetylthranil (BOGER and KLABER), A., i, 466.
compounds of, with cobaltinitrites (CUNNINGHAM and PERKIN), P., 212.
racemic, resolution of, by means of camphoracetic acids (FREYLAN), A., i, 827.
tertiary, as reagents for distinguishing between enolic and ketonic derivatives (MICHAEL and SMITH), A., i, 943.
See also Bases.
Aminoaetals and amino-aldehydes (WOHL), A., i, 46.

Amino-acid, C_{17}H_{19}O_{3}N, and its methyl ester and salts, from acoline (SCHULZE), A., i, 561.

Amino-acids, synthesis of (SORENSEN and ANDERSEN), A., i, 649, 675.
action of carbon disulphide on (KÖRNER), A., i, 509.
decomposition of, by Bacillus proteus vulgaris (NAWASKY), A., ii, 614.

Amino-acids, reduction of, to amino-aldehydes (NEUBERG), A., i, 322.
of byssus (ABDERHALDEN), A., ii, 517.
in meat extracts (MICKO), A., ii, 713.
in urine during pregnancy (van LEER-SUM), A., ii, 715.
fate of, in the dog (FRIEDMANN), A., ii, 205.
new compounds of, with ammonia (BERGELL and FRIEL), A., i, 140, 396.
derivatives of, applicable for synthetic purposes (GABRIEL), A., i, 181.
racemic. See Racemic amino-acids.

Amino-acids, halogen (WHEELER and CLAPP), A., i, 897, 981.
α-Amino-acids, hydrocyclic (SKITA and LEVI), A., i, 884.

Amino-alcohol, C_{17}H_{19}O_{3}N, and its benzoyl derivative, from estragole iodohydrin and dimethylamine (DAUFRESNE), A., i, 19.
C_{17}H_{19}O_{3}N, from estragole iodohydrin and diethylamine (DAUFRESNE), A., i, 20.

C_{17}H_{19}O_{3}N, from the action of nitrons acid on di-p-methoxydiaminostilbene (FISCHER and PRAUSE), A., i, 220.
C_{17}H_{19}O_{3}N, and its salts and their acetyl derivatives, from acoline (SCHULZE), A., i, 501.
and its benzoate hydrochloride and phenylurethane hydrochloride, from the reduction of ethyl β-diethylaminoethyl ketone (BLAISE and MAIRE), A., i, 398.

Amino-alcohols, formation of (DAUFRESNE), A., i, 19; (FOURENAU and TIEFFENAU), A., i, 163; (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 167; (RIEDEL), A., i, 250, 956.
preparation of acyl derivatives of (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 167, 169, 176.

Amino-aldehydes and aminoacetals (WOHL), A., i, 46.
and amino-ketones of the aromatic series, relation between the absorption spectra and chemical constitution of (BALY and MARSSEN), T., 2108; P., 235.
reduction of amino-acids to (NEUBERG), A., i, 322.

Aminoalkyl esters, relation between chemical constitution and physiological action in certain substituted (FYMAN), T., 1793; P., 205.
acylated, preparation of (RIEDEL), A., i, 769.
Aminocarboxylic acids, affinity constants of, as determined by the aid of methyl-orange (Veley), T., 662; P., 50.

Amino-compounds, action of, on chloromethyl sulphate (Houben and Arnold), A., i, 533.

Amphoteric, union of carbon dioxide with (Siegfried and Neumann; Siegfried and Lieberman), A., i, 379.

Aromatic, action of sulphites on (Bucherer and Seyde), A., i, 455. See also under the parent Substance.

Amino-groups, acids as accelerators in the acetylation of (Smith and Orton), T., 1242; P., 132.

N-Amino-groups in heterocyclic compounds (Bulow and Klemann), A., i, 54.

N-Aminoheterocyclic compounds (Franzen and Schueermann), A., i, 293.

Aminohydroxy-acids, synthesis of (Sorensen and Andersen), A., i, 649.

Condensation of, with aromatic aldehydes (Punekedy), A., i, 286.

Amino-ketones and amino-aldehydes, relation between the absorption spectra and chemical constitution of (Baly and Marsden), T., 2108; P., 235.

Acid properties of (Rabe, Schneider, and Braasch), A., i, 361.

Transformations of (Gabriel and Lieck), A., i, 484.

β-Amino-ketones, preparation of (Kohn), A., i, 529.

δ-Amino-ketones (Gabriel), A., i, 648.

ε-Amino-ketones (Gabriel and Colman), A., i, 649.

Amino-lactones from diacetone alcohol (Kohn), A., i, 819.

α-Amino-nitriles, synthesis of (Zelinsky and Stadnikoff), A., i, 770.

Amino-oximes, negative substituted (Steinkopf and Benedek), A., i, 1012.

Brominated (Steinkopf and Grun-upf), A., i, 966.

Ammonia, synthesis of (Wolterbeck), A., i, 400; ii, 174.

Catalytic synthesis of, from its elements (Brients and Woog), A., ii, 34; (Wolterbeck), A., ii, 174.

Production of, by bacteria (Berghaus), A., ii, 413.

Chemical action of radium emanation on (Cameron and Ramsay), T., 984; P., 132.

Ammonia, electrical conductivity in systems containing zinc sulphate, water, and (Shumakoff), A., ii, 457.

Liquid, boiling point of (Franklin), A., ii, 34.

Contact oxidation of (Orloff), A., ii, 582.

The unimolecular course of the decomposition of, by the silent discharge (Le Blanc and Davies), A., ii, 653; (Pohl; Le Blanc), A., ii, 819.

Temperature of dissociation of (Wolterbeck), A., ii, 820.

Distillation of, in presence of magnesium or calcium salts (Kober), A., ii, 593.

Apparatus for the quantitative distillation of (Kober), A., ii, 776.

Equilibrium of, under pressure (Jost), A., ii, 362, 761; (Haber and Le Rossignol), A., ii, 362, 819.

Action of, on phosphorus (Stock and Jahnnsen), A., ii, 583.

Action of, on phosphorus chloronitrile (Besson and Rossset), A., ii, 583.

Microbiochemical formation of, in soil (Perotti), A., ii, 124.

And metals, formation of compounds between (Kraus), A., ii, 486.

And urea, Spiro's and Folin's methods of estimating (Howe and Hawk), A., ii, 426.

Estimation of, in urine (Malfatti), A., ii, 531; (Steel and Gies), A., ii, 776; (Ronchese), A., ii, 983.

Estimation of, in water (Ronchese), A., ii, 320.

And amines, separation of, by means of boiling absolute alcohol (Berthelame), A., ii, 742.

Ammonium amalgam (Smith), A., ii, 38.

Demonstration of the formation of, by electrolysis of ammonium chloride (Schroeder), A., ii, 270.

Ammonium bases, problem of the asymmetric synthesis of (E. and O. Wedekind), A., i, 258.

Ψ-Ammonium bases, constitution of (Gadamé; Kuntze), A., i, 322.

Ammonium compounds, optically active, effect of constitution on the rotatory power of (Jones and Hill), T., 295; P., 28.

Resolution of, by means of tartaric acid (Jones), A., i, 257.

Dependence of the velocity of racemisation of, on the nature of the anion (E. and O. Wedekind and Paschke), A., i, 394.
Ammonium compounds, optically active, autaracemisation of (v. Halban), A., i, 627.
mechanism of the autaracemisation of (Wedekind and Paschke), A., i, 722.
quaternary, double dissociation of (v. Braun), A., i, 627.

Ammonium salts, Cain's theory of (Hantzsch), A., i, 1021.
quaternary, state of, in solution (Wedekind and Paschke), A., i, 722.
experiment with, on soils (Ehrenberg), A., ii, 60, 1068.
calcium cyanamide, and sodium nitrate, manural experiments with (Wagner, Hamann, and Münzinger), A., ii, 622.

Ammonium rhodium bromide and chloride (Gutbier and Hüttlingr), A., ii, 200.
chloride (sal ammoniac), preparation of pure (Hinrichsen), A., ii, 494.
vapour pressure of (Johnson), A., ii, 157; (van Laar), A., ii, 353, 569; (Abegg), A., ii, 466, 812.
mercuric chloride, and water at 30°, in equilibrium (Meerbarg), A., ii, 676.
and dimercuriammonium chloride, double, dissociation of, by water (Gaudencon), A., ii, 188.
influence of, on the solubility of barium carbonate, and vice versa (Kernot, D'Agostino, and Pellegrino), A., ii, 503.
mercuric chloride (white precipitate), reactions of (Schmidt and Krauss), A., i, 139.
acidimetric assay of (Rupp and Lehmann), A., ii, 70.
chromate, dichromate, and trichromate, slow decomposition of, by heat (Ball), P., 136.
dichromate, decomposition of, by heat (Hooton), P., 27.
chromates, double (Gööer), A., ii, 690.
peridate, specific gravity and solubility of (Barker), T., 17.
molybdate, hydrolysis of, in presence of iodates and iodides (Moody), A., ii, 197.
cero- and lanthanio-molybdates (Barker), A., ii, 595.
phosphomolybdate, variations in the composition of (Chesneau), A., ii, 427.
nitrate, utilisation of nitrog. in the form of (Preiffer, Heppner, and Frank), A., ii, 980.

Ammonium nitrite (Meyer and Trützer), A., ii, 181; (Weigheider), A., ii, 265.
sulphate as manure. See under Manure.
calcium sulphate, double. See Ammonium syngenite.
copper calcium sulphates (D'Ans), A., ii, 590.
manganous sulphates (Lang), A., i, 350.
persulphate, electrolytic production of (Consoritium für Elektrochemische Industrie), A., ii, 690.
action of, on metals (Turamentine), A., ii, 104; (Levi, Migliorini, and Ercolini), A., ii, 581.
and sodium peroxide, reaction between (Kempf and Oehler), A., ii, 764.
odxidation of the ammonia in (Levi and Migliorini), A., ii, 885.
use of, in the separation of manganese from copper in acid solutions (Gottschalk), A., ii, 433.
thioantimonate (Donk), A., ii, 763.

Ammonium cyanate and carbamide, isomerism of (Patterson and McMillan), T., 1050; P., 185.
thiocyanate and thiocarbamide, isomerism of (Patterson and McMillan), T., 1049; P., 135.
hydrolysis of aqueous solutions of, in presence of metallic hydroxides (Grossmann), A., i, 512.

Ammonium radicles, chemical dissociation of polyiodides of (Dawson), T., 1308; P., 181.
electrolytic dissociation of polyiodides of (Dawson and Jackson), T., 2063; P., 213.

Ammonium syngenite (D'Ans), A., ii, 182.

Amorphous, colloidal, and crystalline states (v. Weimann), A., ii, 80.

Amygdalin (Rosenthaler), A., i, 197.
hydrolysis of, by emulsin (Auld), T., 1261, 1276; P., 97, 181; (Feist), A., i, 457, 903; (Rosenthaler), A., i, 817.

Amyl alcohol, recovery of, from the acid liquors obtained in the Gerber process (Richmond), A., i, 495.
oxidation of, by a contact process (Oloff), A., i, 306.

Amyl alcohol, sulphur derivatives of, and their optical activity (Hilditch), T., 1619; P., 195.

Amyl alcohol. See also Dimethylcarbinol.

isoAmyl arsenite (Lang, Mackey, and Gortner), T., 1367; P., 150.
Amyl ether, preparation of (SCHROETER and SONDAG), A., i, 497.

Amyl nitrate, effect of, on red blood corpuscles (SLAVU), A., ii, 767.

Amylamine, preparation of (CHEMISCHE WERKE VORM. HEINRICH BYK), A., i, 395.

Amylaminoacetal and its derivatives (PAAL and VAN GEMBER), A., i, 511.

Amylase, physicochemical investigation of (PHILOCHE), A., i, 712; ii, 470.

Amyl glycerol ester, action of pancreatic juice, action of, and its activation by gastric juice (BIERRY), A., ii, 305.

Amyloid degeneration, the chemistry of (HANSSSEN), A., ii, 968.

Amyl piperidine, γ-amino- and its additive salts, carbamide, phenyl-carbamide, and oxamide (BLAISE and MAIRE), A., i, 398.

Amylglycerol and its triacetate (REIF), A., i, 847.

Amyloid degeneration, the chemistry of (HANSSSEN), A., ii, 968.

α-Amynoxy styrene (TIFFENKAU), A., i, 10.

1-Amylpiperidine, γ-amino- and its additive salts, carbamide, phenyl-carbamide, and oxamide (BLAISE and MAIRE), A., i, 398.

α-Amyrin, identity of, with ilicyl alcohol (JUNGFLEISCH and LEROUX), A., i, 1000.

Cinnamic ester of (WINDAUS and WELSCH), A., i, 903.

Anæmia, experimental, blood formation in spleen and liver in (V. DOMARIUS), A., ii, 509.

Anæsthesia, increase in osmotic concentration of the blood during (CARTSON and LUCKHART), A., ii, 304.

Anæsthetics, local, colour test for (LEMAIRE), A., ii, 784.

Analysis, isolation of traces of mineral substances from saline mixtures in (MEILLERE), A., ii, 62.

Analysis, absorption bulbs for use with bottles containing standard solutions, &c. (POZZI-ESCOT), A., ii, 729.

new form of potash bulb for (HILL), P., 182.

apparatus for testing burettes, pipettes, and mercury measuring tubes (v. SPINDLER), A., ii, 625.

gas-generating apparatus for use in (MÜLLER), A., ii, 129.

apparatus for estimations involving distillation (MORGAN and COOK), A., ii, 424.

use of certain organic acids and acid anhydrides for the standardisation of acid and alkali solutions (PHELPS and WEED), A., ii, 730.

comparison between succinic acid, arsenious oxide, and silver chloride for the standardisation of solutions (PHELPS and WEED), A., ii, 750.

preparation of alcoholic potassium hydroxide solution and apparatus for storing the same (SCHOLL), A., ii, 425.

Analysis, adsorption. See Adsorption analysis.

new capillary and capillary-analytical investigations (GOFFELSSROEDER), A., ii, 529.

centrifugal qualitative (JANSEN), A., ii, 891.

chemical, microchemical, and microscopic, use of chloral alcoholate, chloral hydrate, and bromal hydrate solutions in (SCHAER), A., ii, 52.

electrolytic (CLASSSEN), A., ii, 226, 432, 529; (FISCHER), A., ii, 226; (FOERSTER), A., ii, 322, 529; (PERKIN), A., ii, 432.

use of the filtering crucible in (GOOC and BEYER), A., ii, 529.

rapid, of metals (SAND), T., 1572; P., 189.

microchemical (SCHOORL), A., ii, 432, 777; (BOLLAND), A., ii, 1080.

organic, soda-lime apparatus for (DENNSTEDT), A., ii, 225.

organic elementary, new experiences in the simplified method of (DENNSTEDT), A., ii, 321.

of organic compounds (DENNSTEDT and HASSLER), A., ii, 984.

qualitative, rapid method of (POLLARD), A., ii, 1069.

of the common elements (NOYES, BRAY, and SPEAR), A., ii, 533.

of metals of the second group without using hydrogen sulphide or ammonium sulphide (SELVATICI), A., ii, 322.
Analysis, qualitative, of group III. (Caron and Raquet), A., ii, 630. use of sodium dioxide in (Caron and Raquet), A., ii, 630; (Calkhane), A., ii, 635. quantitative, use of sodium peroxide in (Parek), A., ii, 623. refractometric, of organic mixtures (Beythienen and Hennicke), A., ii, 72; (Sundvik), A., ii, 990. spectrum. See under Photochemistry. thermal, quartz protecting tubes in (Schoen), A., ii, 1015. volumetric, preparation of normal hydrochloric acid (Rebenschoff), A., ii, 221. titration of permanganate in presence of hydrochloric acid (Harrison and Perkin), A., ii, 223. use of sodium hyposulphite in (Bollenbach), A., ii, 229. use of thiosulphuric acid in (Casolari), A., ii, 173, 222. Anethole, synthesis of (Behal and Tiffeneau), A., i, 260. methyl iodohydrin (Tiffeneau), A., i, 165. Anglesite, barytes, and celestine, artificial reproduction of, and isomorphous mixtures of these substances (Gaubert), A., ii, 38. Angocopaloric acid and α- and β-Angocopaloresens from Angola copal (Tschirch and Rackwitz), A., i, 96. Anhydride, C₉H₈O₃, from agaricic anhydride (Thoms and Vogelsang), A., i, 5. Anhydrides of α-amino-γ-carboxylic acids and of α-amino-acids (Leuchs and Geiger), A., i, 541. of monobasic acids, action of zinc allyl iodide on (Saytzefl), A., i, 73. acid, mixed organic, new method of preparing (Bougauf), A., i, 791. colour reactions during the hydrolysis of (Stobbe), A., i, 955. ester, of saturated dibasic acids (Mol), A., i, 76. See also Dicarboxylic anhydrides. Anhydrobisphenacylamine and its nitrate and benzylidene derivative (Gabriel and Liec), A., i, 465. Anhydrobrazilinic acid, synthesis of (Perkin and Robinson), T., 489; P., 54. Anhydro-αα'-dimethylhydrophthalide (Mermod and Simonis), A., i, 342. Anhydroglutaric acid, ethyl ester (Mol), A., i, 77. Anhydrohaemaric acid, esters (Küster), A., i, 303. Anhydrohydroxydihydroxydrosorobic acid and its salts (Riedel), A., i, 501. Anhydrolinaric phenol and its acetate and benzolate (Klobb), A., i, 904. Anhydromethylenelectrysalicylic acid, quinine salts (Santi), A., i, 451. Anhydro-o-naphthaquinonesorcinol. See Brazaquinones, 2-hydroxy-. Anhydro-oxalic acid, ethyl ester (Mol), A., i, 76. Anhydro-oxythymenediposphoric acid, decomposition of, by phytase (Suzuki, Yoshimura, and Takaishi), A., i, 235. salts, occurrence of, in plants (Suzuki and Yoshimura), A., ii, 124. calcium magnesium salt. See Phytin. Anhydro-S-phenethyl-3,3'-dinitrophenazothenium (Smiles and Hilditch), T., 150. Anhydrohapontigemin (Hesse), A., ii, 419. Anhydrosoecic acid, ethyl ester (Mol), A., i, 76. Anil, chloro-. See p-Benzoquinone, tetra-chloro-. hydrochloro-. See Quinol, tetrachloro-. Anilhameric acid and its methyl ester (Küster), A., i, 304. Anilides, formation of, from benzhydroxamic acid (Ponzio and Giovetti), A., i, 726. p-toluidides, and α-naphthaldies of normal fatty acids, melting points of (Robertson), T., 1033; P., 120. of certain polybasic aliphatie and aromatic acids, nitration of N-acyl compounds of (Tingle and Blanck), A., i, 778, 893. Anilides, halogenated, preparation of (Mannino and Donato), A., i, 826. ψ-Anilides, acid anilides, and anilo-acids (Meyer), A., i, 25. Aniline and its derivatives, nitration of (Tingle and Blanck), A., i, 778; (Witt and Witte), A., i, 874. action of, on benzoylebenzoic acids (Meyer), A., i, 25. action of dichloroacetic acid on (v. Ostromisslensky), A., i, 82, 888. and its homologues, action of dichloroacetic acid on (Heller and Leyden), A., i, 216. formaldehyde, and sodium hyposulphite, interaction of (Gesellschaft für Chemische Industrie in Basel), A., i, 151. and its homologues, action of glyoxylic acid and of diacetylglucoxal acid on (v. Ostromisslensky), A., i, 889.
Aniline, oxidation of, by halogen acids (OSTROGOVICH and SILBERMANN), A., i, 373.
indulines from (BACOVESCU), A., i, 825.
acetyl derivative. See Acetanilide.
calcium derivative (ERDMANN AND VAN DER SMISSEN), A., ii, 588.
di-o-substituted, preparation of mono-
acetyl derivatives of (SMITH and ORTON), T., 1249; P., 132.
picrate (SUIDA), A., i, 533.
and o-nitro- (VIGNON and ÉVIEUX), A., ii, 664.
m-nitro- (GIBSON), T., 2100; P., 241.
styphnate, m-nitro- (GIBSON), T., 2100; P., 241.
Aniline, 2:6-dibromo-, preparation of (ORTON and PEARSON), T., 735.
2:5-dichloro-, reactivity of diazo-salts of (ROHNER), A., i, 482.
chloronitro-, new (V. OSTROMISLANSKY), A., i, 886.
2:6-diamino-, and 2:3:6- and 2:4:5-tri-
iodo- (KÖRNER and BELASIO), A., i, 779.
m-nitro-, action of bromine or of sodium hypobromite on, and some of
its halogen derivatives (KÖRNER and CONTA RDI), A., i, 523.
iodination of (KÖRNER and BELASIO),
A., i, 779.
p-nitro-, chlorination of (FLÜRS CHEIM),
T., 1772; P., 211.
o- and p-nitro-, melting points of mix-
tures of (TINGLE and ROLKER), A., i, 974.
o-, m-, and p-nitro-, melting point
curves of binary mixtures of, and a new method of determining the
composition of such mixtures (TINGLE and ROLKER), A., i, 408.
solubility of, in alcohol (TINGLE and
ROLKER), A., i, 974.
reactions of, with phenylcarbimide
(MICHAEL and COBB), A., i, 949.
synthesis of piperazine and pyrrole
derivatives from (BORSCH and TITSINGH), A., i, 103.
mercury salts of (JACKSON and
PEAKES), A., i, 523.
2:4:6-trinitro- (WITT and WIT TE), A., i, 875.
Aniline-black, constitution of (MARS-
DEN), A., i, 226.
Aniline colours, absorption of light in
solutions of, from the standpoint of
optical resonance (KALANDER), A., ii, 139.
Anilines, bromo-, substituted, orientation of
a series of (HILL), A., i, 256.
XCIV. ii.
Aniline-p-sulphonic acid (sulphanilic
acid), amides of (GELMO), A., i, 409.
Anilinoacetal (WOHL and LANGE), A., i, 17.
γ-Anilinocetoacetic acid, a-cyano-, ethyl ester, and its hydrochloride
(HENK), A., i, 601.
Anilinoaceto-γ-hydroxyaniline, p-hy-
droxy-, and its hydrochloride (HINS-
berg), A., i, 453.
Anilinobenzoxazole and its acetyl deriv-
ative (YOUNG and DUNSTAN), T., 1052;
P., 136.
Anilinodihydrobenzoxazole. See s-Di-
phenylcarbamide.
β-Anilinodihydropyridazine, 1:3-dinitro-
N-dinitro- (LEEMANN and GRAND-
MOUGIN), A., i, 478.
4-Anilinodiphenyl, 3-amino-, and its
derivatives (DZIURZYŃSKI), A., i, 696.
β-Anilinoethyl ethyl ketone and its
semicarbazone and phenylcarbamide
(BLAISE and MAIRE), A., i, 566.
β-Anilinoethyl propyl ketone and its
phenylcarbamide (BLAISE and MAIRE),
A., i, 566.
3-Anilino-6-hydroxyphenylsulphonapth-
ephonazonium chloride (KEHRMANN
and BRUNEL), A., i, 579.
4-Anilino-1-indoxylbenzene (FRIED-
LÄNDER and SCHULOFF), A., i, 675.
Anilinomethylcarbinol and its hydro-
chloride and picrate (FARBWERKE
VORM. MEISTER, LUCIUS, & BRÜN-
ING), A., i, 415.
Anilinomethyleneomphalthalamic acid,
ethyl ester (DIECKMANN and MEISER),
A., i, 895.
β-Anilinophenosaframine, phenylated,
synthesis of, and its additive salts
(BARBIER and SISLEY), A., i, 64.
Anilinoquinoline, nitro- and nitroamino-
derivatives and their additive salts and
acetyl derivatives (MEIGEN, GARRS,
MERKELBACH, and WICHERN), A., i,
580.
3-Anilinotoluene, 4-nitro- (BORSCH,
WITTE, and BOTHE), A., i, 367.
6-Anilino-2-α- and p-toluidinopyrimid-
ines (JOHNSTON, STOREY, and MCCOL-
LUM), A., i, 838.
6-Anilino-2-p-tolyl-4-methylpyrimidine
(JOHNSTON, STOREY, and MCCOLLUM),
A., i, 838.
Anilinotriphenylamine and p-amino- and
p-chloro- and their acetyl derivatives,
and p-nitro- (GAMBHALIAN), A., i, 1016.
Anilin-acids, acid anilides, and ψ-anilides
(MEYER), A., i, 25.
ψ-Anilopyrine, 4-nitroso-, and its hydro-
chloride (MICHAELIS and MIELECKE),
A., i, 61.
Animal fibres, reducing action of (Ulrich and Schmidt), A., i, 377.

fluids, chemico-physical studies of (Bottazzi), A., ii, 869; (Bottazzi, Buglia, and Jappelli), A., ii, 870.

inose in (Rosenberger), A., ii, 873.

estimation of lactic acid in (Jerusalem), A., ii, 905.

metabolism. See under Metabolism. tissues. See Tissues.

Animals, effects of variations in inorganic salts and reaction on (Moore, Roaf, and Knowles), A., ii, 768.

origin and destiny of cholesterol in (Doree and Gardner), A., ii, 514.

nucleic acids in (Schmirleberg), A., ii, 70.

protein synthesis in (Henriques), A., ii, 207.

growing, calcium foods in (Aron and Sebauer), A., ii, 208; (Aron and Frese), A., ii, 405; (Orgler), A., ii, 606, 872.

Anions. See under Electrochemistry.

Anisaldehyde, hydrogen persulphide (Brunner and Vuilleumier), A., i, 900.

p-Anisic acid (p-methoxybenzoic acid), e-bromoamyl ester (Merck), A., i, 419.

p-Anisic acid, chloroimino- and imino-esters (Hilpert), A., i, 831.

o-Anisidine, 3-nitro-, and its acetyl derivative (Blanksma), A., i, 978.

p-Anisidinesulphonic acid, chloro-, azo-derivative of (Aktien-Gesellschaft für Anilin-Fabrikation), A., i, 1023.

Anisine, re-solution of the iminoazole ring in (Fischer and Prause), A., i, 219.

Anisoin, alkylation of (Irving and McNicoll), T., 1605; P., 191.

Anisole, sulphination of (Smiles and Le Rossignol), T., 755.

Anisole, o-bromodinitro-, o-chlorodinitro-, and o-dinitro-, and its phenylhydrazine salt (Ponzio and Charrrier), A., i, 522.

2-cyano-, nitro- and nitroamino-derivatives of (Blanksma), A., i, 271.

3- and 4-nitro-2-cyano-, and 4:6-dinitro-2-cyano- (Blanksma), A., i, 978.

Anisolesulphinic acid, preparation of (Knovenagel and Kenner), A., i, 971.

α-Anisoyl-β-phenylhydrazine, α-nitro-β-nitroso- (Ponzio and Charrrier), A., i, 582.

AnisyI sulfoxide (Smiles and Le Rossignol), T., 755.

Anisylacetone, isonitroso- (Ponzio and Giovetti), A., i, 895.

γ-Anisylbutyric acid, α-hydroxy- and β-iodo-α-δ-hydroxy-, lactone of (Bougault), A., i, 539.

Anisychloro-isopropyl alcohol, preparation of (Fourneau and Tiffeneau), A., i, 163.

β-Anisycinolinic acids, stereoisomeric, and their esters and salts (Stoerner and Friderici), A., i, 179.

γ-Anisylocrotonic acid, α-hydroxy- (Bougault), A., i, 269, 539.

α-Anisylethylamine and its salts (Busch and Leefhelm), A., i, 153.

Anisylidene chloride (Schmidt), A., i, 654.

Anisylideneacetone hydrochlorides (Francesconi and Cusmano), A., i, 803.

Anisylideneacetyl-1-naphthol. See Methoxybenzylideneacetyl-1-naphthol.

p-Anisylidenemaminodimethylaniline and its hydrochlorides (Moore and Gale), A., i, 369.

Anisylideneaniline hydrochloride (Pope and Fleming), T., 1916.

Anisylideneaminomylideneacetone and its hydrochlorides and bromides (Francesconi and Cusmano), A., i, 802.

Anisylidinemethylhydrazine, benzoyl derivative of (Michaelis and Hadanck), A., i, 1020.

Anisylidenepruvic acid (Bougault), A., i, 269.

iodo-lactone from (Bougault), A., i, 539.

1-Anisyl-2-methylbenziminozoles,o-, m-, and p-, 4:7-dinitro-6-hydroxy, and their salts and derivatives (Meldola and Hay), T., 1674.

β-o-Anisyl-α-methylinamic acids, stereoisomeric (Stoerner and Friderici), A., i, 181.

Anisymethylfurazan, chloro- (Wieland and Semper), A., i, 108.

β-Anisyl-α-methyl-β-phenylhydracrylic acid, ethyl ester (Stoerner and Friderici), A., 181.

Anisyl-o-oxaline, isonitroso-, and its benzoyl and methyl derivatives (Wieland and Semper), A., i, 109.
INDEX OF SUBJECTS.

1243

1. Anisylpiperidine and its picroate (Koenig and Bernhart), A., i, 285.

α-Anisylpropylamine and its derivatives (Busch and Leefheim), A., i, 153.

Anisylsulphone (Smiles and Le Rossignol), T., 755.

γ-Anisylvaleric acid, β-iodo-γ-hydroxy-, lactone of (Bougault), A., i, 538.

Anisyl- See also Methoxyphenyl-

Anode. See under Electrochemistry.

Anode rays. See under Photochemistry.

Annual General Meeting, T., 763; P., 81.

Anthocyanins, formation and chemistry of (V. Portheim and Scholl), A., i, 905.

Anthophyllite from Canada (Evans and Bancroft), A., ii, 604.

Anthoza, skeletal substances in (Mörner), A., ii, 517.

the organic substance of the skeletal tissues of (Mörner), A., ii, 310.

Anthracene from rhin (Oesterle and Tisza), A., i, 905.

oxidation of (Law and Perkin), T., 1637; P., 195.

reduction of, in presence of nickel oxide (Ipatieff, Jakowleff, and Rakitin), A., i, 380.

derivatives, new synthesis of (v. Liebig), A., i, 727.

preparation of, from α-dianthraquinonyl (Scholl), A., i, 428.

complex, preparation of (Badische Anilin & Soda-Fabrik), A., i, 999.

containing nitrogen, preparation of (Farbenfabriken vorm. F. Bayer & Co.), A., i, 699, 1010.

4-Anthraceneazo-1-anthranime (Pisovschii), A., i, 481.

Anthachysone, amino-derivatives (Farbenwerke vorm. Meister, Lucius, & Brünning), A., i, 192.

1:4-Anthradiamine and its salts and diaecetyl derivative (Pisovschii), A., i, 481.

Anthraflavic acid, dichloro-, and its diaacetate and dibenzoate (Wedekind & Co.), A., i, 192.

1-Anthranil and its derivatives (Pisovschii), A., i, 481.

Anthranil, preparation of (Kalle & Co.), A., i, 786, 828.

constitution of, and its nitrosoamine (Heller and Nötzel), A., i, 267.

Anthranilic acid (α-aminobenzoic acid), characteristic reaction of (Pawlewski), A., i, 638.

pirates of (Suida), A., i, 523.

Anthranilic acid, brucine and cinchonine salts, and their optical activity (Hilditch), T., 1390; P., 186.

Anthrancilic acid, 3-hydroxy-, and its hydrochloride (Keller), A., i, 284.

Anthraron, 1:2-dihydroxy-. See Leuco-

Anthrquinone, direct product of alizarin from (Badische Anilin- & Soda-Fabrik), A., i, 191.

antimony pentachloride (Meyer), A., i, 731.

derivatives, colour and affinity for mordants of (Heller), A., i, 995.

containing nitrogen, preparation of (Farbenfabriken vorm. F. Bayer & Co.), A., i, 456.

Anthrquinone, chloroamino-derivatives, and their N-acyl derivatives, preparation of (Badische Anilin- & Soda-Fabrik), A., i, 994.

1:2-dihydroxy-. See Alizarin.

1:4-dihydroxy-. See Quinizarin.

1:8-dihydroxy-. See Chrysazin.

2:6-dihydroxy-. See Anthraflavic acid.

tri-hydroxy-, monomethyl ether from Mortina citrifolia (Oesterle and Tisza), A., ii, 527.

1:2:5-trihydroxy-. See Anthranufin, hydroxy-

1:2:8-trihydroxy-. See Chrysazin, hydroxy-

1:3:5:7-tetrahydroxy-. See Anthra-

chrysone.

thio-derivatives (Farbwerke vorm. Meister, Lucius, & Brünning), A., i, 192.

Anthrquinonecarboxylic acid, β-chloro-

(Heller and Schülke), A., i, 995.

Anthrquinonesulphonic acid, cerium salt (Erdmann and Nieszytka), A., i, 622.

Anthrquinonesulphonic acid, αβ-

hydroxy-, preparation of (Wedekind & Co.), A., i, 661.

Anthrquinone-α-sulphonic acid and its derivatives, replacement of a sulphonic group by hydroxy in (Farben- fabriken vorm. F. Bayer & Co.), A., i, 807.

Anthrquinones, researches on the (Bentley and Weizmann) T., 435; P., 52.

Anthrquinonyl-1-quinoline and -1:5-

diquinoline (Farbwerke vorm. Meister, Lucius, & Brünning), A., i, 365.
2-Anthraquinoylurethane, 1-chloro-, and 1:5-Anthraquinonylurethane, 4:8-dichloro- (Badische Anilin- & Soda-Fabrik), A., i, 994.

Antiaris, hydroxy-, and its triacetetyl derivative, preparation of (Farbwerke vorm. Meister, Lucius, & Brüning), A., i, 897.

Antiaris and its preparation (Kalle & Co.), A., i, 421, 646.

Anti-amylase, serum containing (Gessard and Wolff), A., i, 379.

Antiaris toxica, resin from (Windaus and Welsch), A., i, 903.

Anticatalase, can the existence of an, be demonstrated? (de Waele and Vandevenelde), A., i, 491; (Battelli and Stern), A., i, 589.

Antiferments and enzymes (Jacoby), A., i, 236; ii, 748.

Antimonic acid. See under Antimony.

Antimony, the electro-analytical deposition of (Sand), T., 1572; P., 189.

the ultimate rays of (de Gramont), A., ii, 645.

so-called amorphous (Cohen and Olie), A., ii, 198.

Antimony compounds, oxidised, analysis of (Jacobsen), A., ii, 989.

with chlorine and sulphur (Taverne), A., ii, 198.

Antimony alloys with bismuth, hardness of (Saposnikoff), A., ii, 600.

with cadmium and with iron (Kunakoff and Konstantinoff), A., ii, 390.

with calcium (Donski), A., ii, 280.

with cobalt (Lewkonja), A., ii, 853.

with lead, estimation of arsenic in (Howard), A., ii, 429.

Antimony trichloride as ionising solvent (Klemensiewicz), A., ii, 1043.

chlorofluoride (Ruff, Stäuber, and Graf), A., ii, 585.

pentfluoride, compound of, with nitrosyl fluoride (Ruff, Stäuber, and Graf), A., ii, 584.

trihydride, heat of formation of (Stock and Wrede), A., ii, 257.

decomposition of (Stock, Echenandia, and Voigt), A., ii, 503.

iodide-sulphur (Auger), A., i, 242.

tetraoxide, dissociation pressure of (Foote and Smith), A., ii, 847.

Antimony:—

Antimonic acid, action of potassium iodide and hydrochloric acid on (Kolb and Formhals), A., ii, 599.

Thioantimonic acid, alkali salts (Donk), A., ii, 763, 859.

Antimony selenide, and arsenic and bismuth selenides, compounds of, with silver selenide (Pélabon), A., ii, 587.

sulphate, compounds of, with metallic sulphates (Gutmann), A., ii, 508.

sulphide, purity and volatility of (Youtz), A., ii, 780.

pentasulphide, rapid preparation of (Saktorius), A., ii, 859.

Antimony organic compounds (Kaufmann), A., i, 1031.

Antimony, arsenic, and phosphorus, microchemical detection of traces of (Sjollema), A., ii, 224.

arsenic, and tin, microchemical analysis of (Schoord), A., ii, 777.

estimation of, electrolytically (Scheen; Cohen), A., ii, 636.

estimation of, volumetrically (Kolb and Formhals), A., ii, 636.

estimation of, in alloys and slags (Namiš), A., ii, 326.

and arsenic, iodometric estimation of, in presence of copper (Heath), A., ii, 734.

Antipyrine (1-phenyl-2:3-dimethyl-5-pyrazolone) arsenate and phos-phate (Auroy), A., i, 370.

Apiphylla punctata, spectroscopic and chemical behaviour of the pigment secretion of (Paladingo), A., ii, 53.

Apo-. See under the substance to which apo is affixed.

Apocynin (acetovanillone), isolation and constitution of and its derivatives (Finnemore), T., 1513; P., 171.

new synthesis of, and its benzoyl derivative (Finnemore), T., 1520; P., 171.

Apocynol and its benzoyl derivative (Finnemore), T., 1521; P., 171.

Apocynum cannabinum, constituents of (Finnemore), T., 1513; P., 171.

Appendicitis, microchemical changes occurring in (Williams), A., ii, 1057.

Apples, effect of temperature on the respiration of (Morse), A., ii, 616.

Arabinose, oxidation of (Nef), A., i, 5.
INDEX OF SUBJECTS.

1245

\textit{1-Arabinose}, preparation of, by means of mercuric gluconate (Guérbet), A., i, 123.

\textit{Arabinose-\textit{o-nitrophenyldrazone} (Reclaire)}, A., i, 1014.

\textit{1-Arabinonic acid}, alkaloidal salts (NEF), A., i, 6.

\textit{Arbutin} and some of its derivatives considered with regard to their rotatory power and their hydrolysis by emulsin (Bourquelot and Hérissé), A., i, 356.

and quinol, differentiation between (Lemaire), A., ii, 328.

detection of, in plants (Fichtenholz), A., ii, 995.

\textit{Arc} and \textit{Arc light}. See under Electrochemistry.

\textit{Arc spectra}. See under Photochemistry.

\textit{Arceaidine}, synthesis of, and its constitution (WohI and Johnson), A., i, 199; (Meyer), A., i, 202.

\textit{Arecaidinealdehyde} (1-methyl-A5-tetrahydropropidine-3-aldehyde) (Wohl and Grossé), A., i, 49.

and its oxime, hydrochlorides of (Wohl and Johnson), A., i, 49.

\textit{Arecoline}, synthesis of, and its additive salts, and its constitution (Wohl and Johnson), A., i, 49; (Meyer), A., i, 202.

\textit{Argentite} from Colorado (Van Horn), A., ii, 603.

\textit{Arginine}, histidine, and lysine, amount of, in the hydrolytic products of various animal tissues (Wakeman), A., ii, 209.

experiments on the decomposition of (Ackermann), A., i, 774.

\textit{Argoi}, estimation of tartaric acid in (Puzzi-Escor), A., ii, 740.

\textit{Argon} in radioactive zirconium minerals (V. Anthropoff), A., ii, 943.

preparation of, from air by means of calcium carbide (Fischer and Kinke), A., ii, 688.

refractive index and dispersion of light in (Burton), A., ii, 545.

and helium, thermal conductivity of mixtures of (Wachsmuth), A., ii, 351.

helium, and atmospheric air, magnetic behaviour of, in relation to oxygen (Tanzler), A., ii, 152.

liquid, products of the arc and spark electric discharge in (Fischer and Ilovici), A., ii, 1034.

generation of ions by collision of positive and negative ions in (Gill and Pinduck), A., ii, 798.

\textit{Argyrodité}, an old occurrence of, at Freiberg (Kolbeck), A., ii, 703.

\textbf{Aromatic compounds}, formation of, from hydroaromatic compounds (Körz and Görtz), A., i, 173.

discontinuous cathode luminescence spectra of some (Fischer), A., ii, 909.

calculation of the thermal constants of (Redgrove), A., ii, 812.

polymorphic modifications of (v. Ostromiissensky), A., i, 868.

solid, and the corresponding hexahydro-compounds, mutual solubility of (Mascarelli and Pestalozza), A., i, 527.

\textbf{Aromatic substances}, degradation of, in the human organism (Blum), A., ii, 1052.

\textbf{Arrow poison}, Munchi, and strophanthin (Mines), A., ii, 522.

\textbf{Arsanilic acid}. See under Arsenic.

\textbf{Arsenic}, the ultimate rays of (De Gramont), A., ii, 645.

metallic, polymeric forms of (Erdmann and Reppert), A., ii, 584.

yellow (Linck), A., ii, 176; (Erdmann), A., ii, 275.

and platinum, and arsenic and bismuth, freezing-point diagrams of the binary systems (Friedrich and Leroux), A., ii, 300.

sublimation of (Jonker), A., ii, 1033.

removal of, from liquids and gases (Chemische Fabrik Griesheim-Elektron), A., ii, 656.

and arsenic chloride, action of, on cobalt (Ducelliez), A., ii, 853.

and trypanosomes (Pyman and Reynolds), T., 1180; P., 143; (Barrowcliff, Pyman, and Rempfl), T., 1893; P., 229.

mechanism of the action of, on trypanosomes in the organism (Jacoby and Schütze), A., ii, 771, 973.

action of, on autolysis (Hess and Saxl), A., ii, 986.

in wines from vines which have been treated with arsenical washes (Breteau), A., ii, 887; (Mestrezat), A., ii, 1069.

\textbf{Arsenic alloys} with cobalt, freezing-point curve of (Friedrich), A., ii, 357.

\textbf{Arsenic trichloride}, action of, on nickel (Viguéroux), A., ii, 855.

ammoniacal (Besson and Rosset), A., ii, 686.

\textit{Pentachloride}, compound of, with nitrosyl fluoride (Ruff, Stauber, and Graf), A., ii, 584.

\textit{Trichloride} (arsine), action of, on solutions of halogens, halogen acids, and other oxidising agents (Reckleben and Lockemann), A., ii, 176.
Arsenic trihydride (arsine), action of, on solutions of some metallic salts (Reckleben, Lockemann, and Eckardt), A., ii, 36.
decomposition of (Stock, Echirandia, and Voigt), A., ii, 488.
estimation of, in gaseous mixtures (Reckleben and Lockemann), A., ii, 224.
Arsenious hydroxide, amphoteric character of (Wood), T., 412; P., 15.
ioide-sulphur (Auger), A., i, 242.
oxide (arsenious anhydride), action of, on germanium compounds on (Sachs and Kantonowicz), A., i, 1031.
is, introduced into the organism, eliminated unchanged or as arsenic acid? (Tonegutti), A., ii, 214.
sulphide, colloidal, coagulation of, by barium chloride (Duclaux), A., ii, 942.
Arsenic acid, hydrates of (Auger), A., ii, 483.
Arsenious acid, theory and practice of the iodometric estimation of (Washburn), A., i, 363.
physiological action of (Salkowski), A., ii, 973.
esters (Lang, Mackey, and Gortner), T., 1364; P., 150.
Arsenites, action of, on thiosulphonates (Gutmann), A., i, 972.
Arsenic selenide and antimony and bismuth selenides, compounds of, with silver selenide (Pélamon), A., ii, 587.
sulphates, compounds of, with calcium, lead, and potassium sulphates (Kühl), A., ii, 36.
telluride (Pélamon), A., ii, 687.
Arsenic organic compounds (Pyman and Reynolds), T., 1180; P., 143; (Barrowcliff, Pyman, and Remfry), T., 1893; P., 229; (Morgan and Micklethwait), T., 2144; P., 268; (Auger), A., i, 13, 516; (O. and R. Adler), A., i, 492; (Michaelis), A., i, 590; (Bertheim), A., i, 590, 591; (Benda and Kahn), A., i, 592; (Dehn and Williams), A., i, 721; (Kuratorium der Georg & Franziska Speyerschen Studienstiftung), A., i, 747; (Benda), A., i, 747; (Blumenthal and Herschmann), A., i, 878.
Arsinic acids, aromatic (Pyman and Reynolds), T., 1180; P., 143; (Benda), A., i, 747.
Arsenic organic compounds:—
Arsenic acids, aromatic, and their physiological action (Barrowcliff, Pyman, and Remfry), T., 1893; P., 229.
primary aromatic (O. and R. Adler), A., i, 492.
Arsanlic acid (p-aminoethylarsinic acid), acyl derivatives of (Kuratorium der Georg & Franziska Speyerschen Studienstiftung), A., i, 591.
homologues and derivatives of (Benda and Kahn), A., i, 591.
Atoxyl, stability of (Yakimoff), A., i, 492.
diazo-reaction of (Covelli), A., ii, 1000.
action of, in the organism (Igersheimer), A., ii, 1061.
Cacodylic acid, tetraiodo-, and its sodium salt (Auger), A., i, 14.
Arsines, reactions of (Dehn, Wilcox, and Williams), A., i, 720.
Arsenic, micro-chemical reactions of, applicable to medical-legal investigations (Deniges), A., ii, 1070.
mercurous nitrate as a microchemical reagent for (Deniges), A., ii, 1070.
antimony, and tin, microchemical analysis of (Schoorl), A., ii, 777.
antimony, and phosphorus, microchemical detection of traces of (Sjollema), A., ii, 224.
detection of, by means of mercuric chloride solution (Lochmann), A., ii, 532.
detection of, by means of the Marsh apparatus (Struve), A., ii, 131.
detection of traces of, in various substances, and the sensibility of the usual methods (Nieuwland), A., ii, 896.
detection of, in fabrics (Behre), A., ii, 533.
detection of, in sulphur (Brand), A., ii, 532.
detection of, in urine (Salkowski), A., ii, 734.
estimation of (Jannasch and Heinmann), A., ii, 490.
estimation of, by the Gutzeit method (Sanger and Black), A., ii, 64.
and antimony, iodometric estimation of, in presence of copper (Heath), A., ii, 734.
estimation of, in antimony lead alloys (Howard), A., ii, 429.
Arsenic, estimation of, in iron ores (GUEDRAS), A., ii, 984.
estimation of, in urine (SANGER and BLACK), A., ii, 65.
Arsenic phosphorus group, allotropic modifications of the elements of the
(LINCK), A., ii, 176, 373; (ERDMANN), A., ii, 275.
Arsenicous acid and compounds and Arseneites. See under Arsenic.
Arsenophananeic acid, iron salt, and arsenious acid, behaviour of, in the
organism (SALKOWSKI), A., ii, 973.
Arsine. See Arsenic trihydride.
Arsenic acids. See under Arsenic.
Artamisin, new reduction products of (BERTOLO), A., i, 560.
Aryl halides, interaction of, with magnesium (SPENCER and STOKES),
T., 68.
Arylazaoacetacetic acids, ethyl esters, acylhydrzones of, and their conversion
to derivatives of 4-arylazo-3-methyl-5-pyrazolones with an acid radicle
attached to the primary nitrogen atom (BULOW and SCHAUB), A., i, 704.
4-Arylazo-3-methyl-5-pyrazolones, derivatives of, with an acid radicle
attached to the primary nitrogen atom, formation of, from ethyl aryl-
zoacetacetateacetylhydrazones (BULOW and SCHAUB), A., i, 704.
8-Arylaminic acids, stereoisomeric (STORMER and FRIDERICI), A., i, 179.
Arylsulphon-ethenylamidines and -thio-
acetamides, action of alkyl haloids on
(TRÖGER and LINDBERG), A., i, 633.
Arylsulphonylbenzidines and their
diazonium salts (MORGAN and BICKLETHWAIT), T., 614.; P., 51.
Arylsulphonyl-α-naphthylamines, con-
densation of, with p-aminophenols
(HEMISCHE FABRIK GRIESEMANN,
ELEKTRON), A., i, 209.
Arylthioacetic acids (arylthioglycollic
acids), preparation of (KALLE & CO.),
A., i, 605, 940, 983.
Asaryaldehyde, compound of, with
aniline hydrochloride, synthesis of
(GATTERMANN), A., i, 34.
Ascaridol (SCHIMMEL & CO.), A., i, 667.
Aseptic liquids, reservoir for storing
(GAUCHE), A., ii, 613.
Ash analysis, estimation of phosphorus in
(LEAVITT and LECLERC), A., ii, 428, 531.
Asparagine and other amides, nutritive
value of (SCHULZE), A., ii, 960.
hydrogen peroxide (TANATAR), A., i, 400.

Aspartic acid, condensation of, with
aminopinenedicarboxylic acid (GOD-
DEN), T., 1173.; P., 144.
and glutamic acid as food-stuffs
Aspergillus niger, influence of potassium
cyanide on the respiration of
(SCHROEDER), A., ii, 413.
Favourable influence of small quantities
of zinc on the growth of (JAVIL-
LER), A., ii, 124.
Fixation of zinc by (JAVILIER), A., ii, 317.
Atacamite, synthesis of (SKINDER), A.,
i, 381.
Atmospheric air, presence of rare gases
in, at different heights (TEISSERENC
DE BORT), A., ii, 783.
Heavy constituents of (RAMSAY; MOORE), A., ii, 840.
Percentage of the inactive gases in; a
Correction (RAMSAY), A., ii, 688.
Spectrum of the lighter constituents
of (WATSON), A., ii, 786.
Argon, and helium, magnetic behaviour
of, in relation to oxygen (TANZLER),
A., ii, 152.
Which has been passed between spark-
ing electrodes, condition of (DE
BROGLIE), A., ii, 341.
Origin of ozone in, and the causes of
the variation of carbon dioxide in
(HENRIET and BONYSSY), A., ii,
578.
Of Cambridge, amount of radium
eemanation in the (SATTERLY), A.,
ii, 918.
Of Chicago, estimation of radium
eemanation in the (ASHMAN), A., ii,
918.
Of Montreal, amount of radium emanation
in the (EVE), A., ii, 7, 919.
Of New Haven and of Rome, consti-
ituents of the radioactivity of the
(DADOURIAN), A., ii, 453.
Relative quantities of ions produced
in, at Rome by the solid transforma-
tion products of radium and of
Thorium (BLANC), A., ii, 452.
Over the open sea, radioactivity of
(KRUNGE), A., ii, 80.
Amount of radioactive emanation in,
from the soil (GOCKEL), A., ii, 452.
Analysis of the gases non-liquefiable in
liquid air in (BORDAS and TOUFLAIN), A., ii, 943.
Detection of small quantities of carbon
Monoxide in (OUIER and KOHN-
ABREY), A., ii, 631, 632.
estimation of carbon monoxide in
(MORGAN and MCWHORTER), A., ii,
66.
Atmospheric air, volumetric estimation of carbon dioxide and other acids in (HENRIET and BONYSSY), A., ii, 734.

new method of estimating mercury vapour in (MÉNIÈRE), A., ii, 433.

Atom, number of corpuscles in the (BOSLER), A., ii, 367.

Atoms, demonstration of a natural relation between the volumes of, in compounds under corresponding conditions and that of combined hydrogen (Le BAS), A., ii, 667.

Atomic decomposition and spectral series (BERNOULLI), A., ii, 1001.

Atomic heats. See under Thermochemistry.

Atomic hypothesis, significance of the (KURBATOFF), A., ii, 97.

and the energetic theory of the universe (PISSARJEWSKY), A., ii, 478.

are the stoicheiometrical laws intelligible without the? (WALD), A., ii, 367; (KUHN), A., ii, 826.

Atomic volume, atomic heat, compressibility, and thermal expansion of metals, relation between (GRÜNEISEN), A., ii, 563.

Atomic weight, choice of the most probable value for an (NOYES), A., ii, 367.

of the simplest ponderable substance, pantogen, determination of the (HINRICHS), A., ii, 1027.

of bismuth (GUTBIER and BIRCKENBACH), A., ii, 600.

of carbon, nitrogen, and oxygen (LEDUC), A., ii, 271.

of chlorine (NOYES and WEBER), A., ii, 371; (EDGAR), A., ii, 577.

relative, of chlorine and hydrogen (GRAY and BURT), P., 215.

of columbium (BALKE and SMITH), A., ii, 1044.

of europium (JANTSCH), A., ii, 282.

of hydrogen (NOYES and WEBER), A., ii, 100, 367.

of lead (BAXTER and WILSON), A., ii, 281.

of nitrogen, application of the method of limiting densities to the (GUYYE), A., ii, 17.

of nitrogen, oxygen, and carbon (LEDUC), A., ii, 271.

of palladium (KEMMERER), A., ii, 1046.

of radium (WILDE), A., ii, 141, 1027; (THORPE), A., ii, 448.

of tellurium (MARKWALD), A., ii, 33; (BAKER), A., ii, 483.

Atomic weights, report of the International Committee on, P., 2.

table of, P., 5.

Atomic weights, the so-called physicochemical, and the calculation of the weight of a normal litre of gases (HINRICHS), A., ii, 98.

commensurability of (HINRICHS), A., ii, 573.

symmetry in the law of (DELAUNAY), A., ii, 269.

indestructibility of matter and the absence of exact relations among the (COMSTOCK), A., ii, 477.

method of calculating (DUBREUIL), A., ii, 936.

of the elements (WILDE), A., ii, 1027.

certain relations between the (DELAUNAY), A., ii, 97.

observations and deductions obtained from a consideration of the numbers given for the, by the International Committee (1905), which lead to a rational determination of the constitution and structure of each element (COLLINS), A., ii, 170.

of sixteen elements, calculation of the (HINRICHS), A., ii, 574.

Atoxyl. See under Arsenic.

Atoxyl poisoning. See under Poisoning.

Atrolactic acid and p-methoxyatrolactic acid, comparative study of the dehydration of (BOUGAULT), A., i, 340.

Atropine and its derivatives (WOLFFENSTEIN and MAMLOCK), A., i, 281.

and allied alkaloids, physiological action of (WEBSTER), A., ii, 412.

behaviour of, in various animals (CLOETTA), A., ii, 1061.

Aurin dimethyl ether and its hydrate (HERZIG), A., i, 880.

Austenite (MAUREK), A., ii, 489; (LE CHATELIER), A., ii, 490.

Autolysator, an apparatus for the automatic estimation of carbon dioxide (KEANE and BURROWS), A., ii, 735.

Autolysis, action of arsenic on (HESS and SAXL), A., ii, 968.

behaviour of creatine in (STANGASINGER; GOTTLIER and STANGASINGER), A., ii, 515; (ROTHMANN), A., ii, 967.

influence of inorganic colloids on (ASCOLI and IZAR), A., ii, 121, 713.

action of certain gases on (BELLAZZI), A., ii, 1055.

post-mortem (JACKSON), A., ii, 407.

Autoracemisation of optically active ammonium salts (V. HALBAN), A., i, 627.

of optically active ammonium salts, mechanism of the (WEDEKIND and PASCHKE), A., i, 722.
Autoxidation, a visible (lecture experiment) (Knecht), A., ii, 270.

Auroxochromic actions, characterisation of (Hantzsch and Staiger), A., ii, 447.

Avogadro-Guldberg law, the (Kurbatoff), A., ii, 812.

Ayapana oil (Semmler), A., i, 279.

Azelaic acid, calcium salt, distillation of (Harries and Tank), A., i, 85.

Azelaone, formation of (Harries and Tank), A., i, 35.

Azine, C₆H₂₅O₄N₂, and its salts, from the oxidation of p-dianisylamine (Wieland), A., i, 1016.

Azines, preparation of certain (Ponzio and Giovetti), A., i, 834.

from 7-hydroxy-β-naphthaquinone (Kehrmann and Brunel), A., i, 579.

relation of, to quinoxalines (Fischer and Schindler), A., ii, 221.

m-Azoanisole (Rotański), A., i, 374.

Azobenzene, measurement of the effect of certain hyposochrome and bathochrome groups on the colour of (Gorke, Köppe, and Staiger), A., i, 477.

action of mercuric acetate on (Smith and Mitchell), T., 847.

hydrolzoride (Weinland and Reichsle), A., i, 974.

Azobenzene, p-amino-, and its N-acyl derivatives, coloured salts of (Hantzsch and Hilscher), A., i, 484.

2:2'-dichloro-4:6':6'-tetronitro (Leemann and Grandmougin), A., i, 479.

p-hydroxy-, See Benzeneazophenol.

2:4:2':4'-pentanitro-, and its potassium salts (Leemann and Grandmougin), A., i, 478.

s-hexonitro-, and its additive compounds with hydrocarbons, and reactions with primary amines (Leemann and Grandmougin), A., i, 478.

Azobenzene-4'-arsonic acid, 4-hydroxy-, and its sodium salts (Barrowcliffe, Pyman, and Rempfy), T., 1896.

Azobenzene-p-hydrazinesulphonic acid and its condensation with aldehydes and ketones (Tröger and Müller), A., i, 1025.

Azobenzensulphonic acids, amino-, constitution of (Hantzsch and Hilscher), A., i, 469; (Hewitt), A., i, 581; ii, 269.

4-Azo-1-p-bromophenyl-5-methyl-3-pyr-azolone (Michaelis and Stiegler), A., i, 211.

Azo-o-carboxylic acids, supposed molecular transposition in (Tiffeneau), A., i, 227; (Freundler), A., i, 228.

4-Azo-3-chloro-1-p-bromophenyl-5-methylpyrazole (Michaelis and Stiegler), A., i, 212.

Azo-compounds, constitution of (Tiffeneau), A., i, 227; (Freundler), A., i, 228.

constitution and colour of (Fox and Hewitt), T., 333; P., 6.

reduction of, by means of sodium hyposulphite (Franzen and Stieldorf), A., i, 113.

replacement of the sulphonate by the cyan- and carboxyl-groups in (Lange), A., i, 300.

from the o-aminophenols and 2-8-dihydroxynaphthalene-6-sulphonic acid (Chemische Fabrik Griesheim-Elektron), A., i, 480.

Azo-compounds, amino- (Hantzsch and Hilscher), A., i, 469; (Hewitt), A., i, 581; (Hantzsch), A., i, 706.

yellow azo- and violet quinonoid salts of (Hantzsch and Hilscher), A., i, 469, 484.

hydroxy- (Auwers and Eisenlohr), A., i, 229.

constitution of (Auwers), A., i, 477.

constitution of, and the action of diazomethane and of mercuric acetate on (Smith and Mitchell), T., 842; P., 70.

transformation of (Auwers and Eckardt), A., i, 480.

p-hydroxy-, relation between quinone-hydrazones and (Borsche), A., i, 66.

salts of, with acids, colour and constitution of (Fox and Hewitt), T., 333; P., 6.

Azo-coupling, influence of hydroxyl ions on (Heller), A., i, 300.

Azo-derivatives of naphthalenoid triazines (Cassella & Co.), A., i, 482.

5-Azodiethylphthalide (Bauer), A., i, 274.

Azo-dyes, position of entrance of the diazo-group in the formation of (Scharlin and Kaljanoff), A., i, 704.

reaction of, with diazo-salts (Lwoff; Grandmougin), A., i, 483.

from the aminonitrides of the higher fatty acids (Sulzberger), A., i, 226.

5-Azoeugenol derivatives (Auwers), A., i, 228.

Azoidime (hydrazoic acid, hydronitrile acid), preparation of (Stolle), A., i, 917; (Thiele), A., ii, 940.
**Azoimideaeptic acid and its ethyl ester and salts (CURTIUS, DARAPSKY, and Bockmühl), A., i, 145.**

**Azoimideacetylaizomide (Curtius, Darapsky, and Bockmühl), A., i, 145.**

**Azoimideacetylyhydrizide and its benzylidene derivative and hydrochloride (Curtius, Darapsky, and Bockmühl), A., i, 144.**

**Azoimides, preparation of (Darapsky), A., i, 106.**

**Azomethine compounds, colour and constitution of (Pope), T., 552; P., 24; (Pope and Fleming), T., 1914; P., 228.**

**Azonium compound from 7-hydroxy-β-naphthaquinone (Kehrmann and Brunel), A., i, 579.**

**p-Azophenyl mercaptan, 4:4'-dinitro-diphenyl ether of (Fromm and Wittmann), A., i, 632.**

**IsoAzoAtates. See iso Diazocompounds.**

**Azotobacter and radiobacter, the chemical changes involved in the assimilation of free nitrogen by (Stöklasa), A., ii, 880; (Stöklasa, Ernest, Sraňák, and Vítek), A., ii, 975.**

**Azotobacter, fixation of atmospheric nitrogen by pure cultures of (Beyerinck), A., ii, 975.**

**Azotobater and radiobacter, inoculation experiments with (Lipman and Brown), A., ii, 615.**

**p-Azoxy-a-alkylcinnamic acids, esters, and their liquid crystals (Vorlander and Kasten), A., i, 642.**

**m-Azoxyanisole (Rotarski), A., i, 374.**

**Azoxybenzene, products of reduction of (Berry), P., 211.**

**Azoxybenzene, bromo dinitro (Flurscheid and Simon), T., 1480.**

**Azoxy-compounds (Rotarski), A., i, 374.**

**preparation of (Dieffenbach), A., i, 541.**

**aromatic, formation of, from nitro-derivatives (Flurscheid and Simon), T., 1463.**

**Azoxystilbenedicarboxylic anhydrides, 2:2' and 3:3' (Heller), A., i, 217.**

**Azoxy-xylene, dinitro (Flurscheid and Simon), T., 1480.**

**B.**

**Bacillo-casein (Auclair and Paris), A., ii, 315.**

**Bacillus coli communis, chemistry of the (Leach), A., ii, 56.**

**diphtheria, formation of acid by the (Lubenau), A., ii, 722.**

**Bacillius, Koch's, chemical constitution and biological properties of the protoplasm of (Auclair and Paris), A., ii, 315.**

**Bacillus vulguris, decomposition of amino-acids by (Nawiasky), A., ii, 614.**

**tuberclose, composition, digestion, and absorption of (London and Riw-kind), A., ii, 870.**

**action of chlorine in the (Mouss and Gouf), A., ii, 123.**

**typhosus, action of heavy metals on (Moore and Hawkes), A., ii, 772.**

**survival of, in soil (Mair), A., ii, 315.**

**Bacteria, galvanotropism in (Abbott and Life), A., ii, 614.**

**part played by, in the formation of higher alcohols during fermentation (Pringsheim), A., ii, 723.**

**as agents in the oxidation of amorphous carbon (Potter), A., ii, 524.**

**fixation of nitrogen in soil by free, and its importance for the nutrition of plants (Koch, Litzendorf, Krull, and Alves), A., ii, 56.**

**formation of sulphates by, in sewage purification (Rouchy), A., ii, 1063.**

**production of ammonia by (Berghaus), A., ii, 413.**

**the catalases of (Jorns), A., ii, 880.**

**which oxidise hydrogen, assimilation of carbon in (Ledeoff), A., ii, 56.**

**nitrogen-fixing (Löhnis and Pillai), A., ii, 522.**

**nitrogenous, nutrition of (Krzemieniewska), A., ii, 722.**

**See also Nitrification.**

**soil, relation of, to the decomposition of nitrogenous organic matter (Hoffmann), A., ii, 414.**

**solvent action of, on the insoluble phosphates of raw bone-meal and natural raw rock phosphates (Sackett, Patten, and Brown), A., ii, 415.**

**estimation of the reducing power of (Wichern), A., ii, 1063.**

**See also Bacillus, Fermentation, Microbe, Micro-organisms, and Yeast.**

**Bakankosin (Bourquelot and Hérissey), A., i, 1001.**

**β-Balaban, from balata (Cohen), A., i, 883.**

**Balance Sheets of the Chemical Society and of the Research Fund. See Annual General Meeting, T., 769.**

**Balances with non-metallic pans (Bornemann), A., ii, 171.**
INDEX OF SUBJECTS.

Balata, phytosterols from (COHEN), A., i, 883.

Band spectra. See under Photochemistry.

β-Baptigcin, ψ-Baptigenin, and ψ-Baptigenin (GORTER), A., i, 98.

β-Barbaloin, formation of, from barbaloin, and its existence in several aloes, and its chloro- and bromo-derivatives (LÉGER), A., i, 40.

Barbituric acid, preparation of (BOEHNINGER & SÖHNE), A., i, 464.

derivatives, liberation of iodine from hydriodic acid by (WHITELEY), P., 288.

Barium, the long wave-length portion of the spectrum of (HOELLER), A., ii, 546.

Barium arsenate and arsenite (ROSENTHALER), A., ii, 522.

carbonate, influence of ammonium chloride on the solubility of, and vice versa (KERNOT, D’AGOSTINO, and PELLEGRINO), A., ii, 508.

influence of addition of chloride on the reaction between, carbon, and nitrogen (KÜHLING, and BERKHOLD), A., i, 143.

See also Witherite.

hydrogen carbonate (KEISER and LEAVITT), A., ii, 1036; (KEISER and MCMASTER), A., ii, 1037.

chloride, and copper and sodium chlorides and water, the system (SCHREINEMAKERS and DE BAAT), A., ii, 1020.

and sodium sulphate, antagonistic action of, on the heart action (SCAFFIDI), A., ii, 520.

separation of lithium chloride from KAHLENBERG and KRAUSKOFF), A., ii, 777.

ammonium chromate (GRÖGER), A., ii, 690.

nitrate, polymorphism of (BARLOW and POPE), T., 1532.

nitrite, molecular volumes of (RAY), P., 240.

oxide (baryte), anhydrous, heat of formation of (DE FORCRAND), A., ii, 155.

hydrates of (DE FORCRAND), A., ii, 764.

dioxyde or peroxyde, action of, on gold (MEYER), A., ii, 47.

evaluation of (CHIWAŁA), A., ii, 431.

dioxyde carbonate (WOLFFENSTEIN and PETNIEK), A., ii, 183.

iron silicate. See Taramellite.

silicate, preparation of (GOLDSCHMIDT), A., ii, 1037.

sulphate, colloidal (RECOURA), A., ii, 692.

Barium sulphate. See also Barytes.

sulphide, compound of, with nickel sulphide (I. and L. BELUCCI), A., ii, 196.

Barium cyanide, preparation of, from barium cyanamidites (BADISCHEN ANILIN- UND SODAFABRIK), A., i, 770.

platinocyanide (LEVY), A., i, 252.

Barium, detection of, in strontium salts (CARON and RUAUET), A., ii, 535.

estimation of small amounts of, in rocks (LANGLEY), A., ii, 985.

quantitative separation of, from strontium (KAHAN), A., ii, 133.

Barley, bio-chemistry of (FORD and GUTHRIE), A., ii, 218.

translocation of nitrogen compounds into the embryo of, from the endosperm and from artificial culture solutions (BROWN), A., ii, 882.

phosphoric acid in (WINDISCH), A., ii, 528.

water-soluble polysaccharides of (BROWN), A., ii, 978.

manorial experiments on (DAIKUHARA), A., ii, 128.

Barometer, a sensitive temperature compensated (GREEN), A., ii, 826.

Baryta. See Barium oxide.

Barytes, specific heat of (LATSCHENKO), A., ii, 758.

celestine, and anglesite, artificial reproduction of, and isomorphous mixtures of these substances (GAUBERT), A., ii, 33.

from the Binnenthal, Switzerland (BAUMHAUER and TRECHMANN), A., ii, 508.

Basalt, nephelitic, new vein of, containing nosite (nosean) in Vincentino (MADDALENA) A., ii, 864.

Base, C_{2}H_{2}O_{3}N_{2}, and its picrolonate, from urine (ENGELAND), A., ii, 1036.

C_{2}H_{11}N, and its platinichloride, from mistletoe (LEPRINCE), A., ii, 53.

C_{2}H_{17}N, from the dioxime of the ketone, C_{2}H_{14}O_{2} (SEMMLER and BARTELT), A., i, 335.

C_{2}H_{11}N, and its salts, from the hydrolysis of ψ-phenaliminobutyric acid (GABRIEL and COLMAN), A., i, 275.

C_{2}H_{10}O_{2}N_{2}, secondary, and its hydrochloride, from chlorodimethylethylcarbinol and ammonia (RIEDEL), A., i, 769.

C_{2}H_{11}O_{2}N_{2} and its hydrochloride, from cyclobutahone nitrosate (DEMjanosoff), A., i, 329.

C_{10}H_{26}O_{2}N_{2} from urine (ENGELAND), A., ii, 1056.
Base, \( \text{C}_6\text{H}_{15}\text{ON} \), hydriodide of, from bisanhydrophenacylamine (Gabriel and Lieck), A., i, 465.

\( \text{C}_6\text{H}_{12}\text{N}_2\text{S} \), and its salts, from the reduction of tetraethylthionine (Gnehm and Schindler), A., i, 111.

\( \text{C}_6\text{H}_{12}\text{O}_4\text{N} \), secondary, from phenyl-chlorodimethylcarbinol and ammonia (Riedel), A., i, 769.

\( \text{C}_6\text{H}_{12}\text{O}_4\text{N} \), and its hydrochloride, from tetramethyl-2:4-diaminobenzaldehyde and phloroglucinol (Sach and Appenzeller), A., i, 187.

Bases, affinity constants of, as determined by the aid of methyl-orange (Veley), T., 652, 2122; P., 50, 238.

conductive and ionisation of, in aqueous solutions at high temperatures (Noyes, Melcher, Cooper, Eastman, and Kato), A., ii, 347.

and acids, diagrammatic representation of equilibria between, in solution (Henderson), A., ii, 675.

rongalite, and formaldehyde, reaction of (Binz and Isaac), A., i, 940.

aromatic, condensation products of dibromo-\( \rho \)-hydroxybenzyl bromide with (Auwers and Dombrowski), A., i, 333.

organic, contact oxidation of (Orloff), A., ii, 582.

hydrofluorides of (Weinland and Reischle), A., i, 974.

detection of, in urine (Engeland), A., ii, 1056.

primary, secondary, and tertiary, characterisation of, by the use of \( \alpha \)-dibromo-\( \gamma \)-pentane (V. Braun), A., i, 677.

tertiary, addition of bromoaconitriile to (V. Braun), A., i, 675.

weak, hydrolysis of, and its variation with temperature (Lundén), A., ii, 164.

See also Amines.

Basic slag. See Slag, basic.

Basilicum oils from Mayotte (Schimmel & Co.), A., i, 667.

Baths, safety apparatus for (De Koninck), A., ii, 681.

Bauxium, Bayer's (Griner and Urbain), A., ii, 105.

Beans, the protein changes taking place in, when kept in the dark (Butkewitsch), A., ii, 884.

Beer, origin and variations of sulphates in (Münz and Trillat), A., ii, 782.

sarcine causing disease in (Miskovsky), A., ii, 526.

Beer yeast. See Yeast.

Beeswax. See under Wax.

Beet (sugar), amount of nutrients utilised by, in the first year and its relation to the amount of sugar in the roots (Andrlik and Urban), A., ii, 1066.

a levorotatory substance found in altered (Weisberg), A., i, 505.

peroxydases from (Ernest and Berger), A., i, 72.

carbohydrate metabolism of the (Strakosch), A., ii, 125.

cultivation of (Saillard), A., ii, 618.

action of manganese compounds on (Grégoire, Hendrick, and Carpiaux), A., ii, 529.

the storage and transportation of sucrose in the (Strohmer), A., ii, 726.

Beet juice, darkening of (Gonnermann), A., ii, 126.

optically active non-saccharine substances in, which are eliminated by the action of lime, and their polarimetric estimation (Herles), A., ii, 1077.

Behenic acid, bromo-, calcium, magnesium, and strontium salts (Farbenfabriken vorm. F. Bayer & Co.), A., i, 122.

\( \beta \)-bromo-, and \( \beta \)-hydroxy-, and its acetyl and iodo-derivatives, and sodium salts (Epiphanno), A., i, 244.

iodo-, calcium salt (saiodin), behaviour of, in the organism (Basch), A., ii, 521; (Abderhalden and Kautzsch), A., ii, 611.

ethyl ester (Farbenfabriken vorm. F. Bayer & Co.), A., i, 310.

\( \gamma \)-Behenolactone (Shukoff and Schestakoff), A., i, 755.

Bengu-copalic acid, -copalonic acid, and -copaloresens from Benguela-copal (Engel), A., i, 559.

Benzo-. See Benzo-, Benzoyl-, and under the parent Substance.

Benzoaldehyde, reduction of, in presence of iron (Ipatieff), A., i, 347.

condensation of, with cyclic acetone bases (Pauly and Richter), A., i, 285.

velocity of the reaction between bromine and (Herz and Dick), A., ii, 762.

condensation of, with cyclopentanone (Kaufmann), A., i, 986.

action of, on pyridine magnesium organic compounds (Oddo), A., i, 27.

Benzaldehyde, diacetate from (Law), A., i, 321.
hydrogen persulphide (Brunner and Vuilleumier), A., i, 900.

Benzaldehyde, 2-bromo-4-hydroxy-, 2-chloro-4-hydroxy-, and 3:5-di-nitro-2:4-dihydroxy-, and their derivatives, synthesis of (Gattermann), A., i, 30.
o-, m-, and p-chloro-, and m- and p-nitro-, semicarbazones of (Law and Perkin), T., 1635; P., 195.
chloro-o-nitro-, preparation of the three (Schwalbe and Jochheim), A., i, 1019.
4-hydroxy-, ethylene and trimethylene ethers of, and their derivatives, synthesis of (Gattermann), A., i, 34.
dihydroxy-, methyl ether of, and its oxime, phenylhydrazone, and sodium derivative from the root of a species of Chlorocodon (Goulding and Pelly), P., 62.
o-nitro-, condensation of, with aromatic hydrocarbons in presence of concentrated sulphuric acid (Kliegl), A., i, 549.
condensation of, with γ-picoline (Löwensohn), A., i, 51.
reaction of, with potassium cyanide (Ekecrantz and Ahlqvist), A., i, 347; (Topovici), A., i, 550.
diethylacetol of (Kliegl), A., i, 82.
2:4-dinitro-, 2:4-bisdimethylaminonil of (Sachs and Appenzeller), A., i, 227.

Benzaldehydecyanohydrin from amygdalin (Feist), A., i, 437, 903; (Rosenthaler), A., i, 817.

Benzaldehydehydraldehydrazone, action of nitrobenzene on, in the light (Ciussa), A., i, 400.

Benzysaladoxine, p-iodo-, velocity of rearrangement of, in n-propyl tartrate (Patterson and McMillan), T., 1047; P., 135.

Benzamide, condensation of, with salicylaldehyde (Titherley and Marples), T., 1983; P., 229.

Benzamide, 2:4:6-tribromo-, crystallography of (Jaeger), A., i, 988.

Benzamidina (Ekecrantz and Ahlqvist), A., i, 993.

Benzanthrone, an old derivative of (Liebemann and Roka), A., i, 427.
alkyl derivatives, preparation of (Badische Anilin- & Soda-Fabrik), A., i, 993.

Benzanthrone, bromo- and chloro-, preparation of (Badische Anilin- & Soda-Fabrik), A., i, 661.
1- and 2-hydroxy-, preparation of (Badische Anilin- & Soda-Fabrik), A., i, 193.

Benzanthronequinoline, bromo-, preparation of (Badische Anilin- & Soda-Fabrik), A., i, 661.

Benzene, structure of (V. Ostromisslensky), A., i, 868.
and its homologues, absorption spectra of the vapours of, and of solutions of benzene (Hartley), A., ii, 243.
toluene, and acetone, dispersion in, electric spectra of (Colley), A., ii, 909.
action of aluminium chloride and hydrogen chloride on (Gustavson), A., i, 328.
aluminium bromide, electrolysis of (Neminsky and Plotnikoff), A., i, 407.
iodechlorides and iodoxy- and iodonium compounds of, preparation of (lecture experiment) (Willgerodt), A., i, 408.
disulphoxide, p-bromo-(Knoevenagel and Polack), A., i, 971.
isomeric substitution products, simultaneous formation of (Hollemann), A., i, 985.

Benzene, structure of (V. Ostromisslensky), A., i, 868.
detection and estimation of small quantities of, in alcohol (Holde and Winterfeld), A., ii, 435.
estimation of, in illuminating gas (Dennis and McCarthy), A., ii, 435.
estimation of carbon disulphide in (Bay), A., ii, 226.
Benzene, bromo-, poisoning by. See under Poisoning.
1:2:3-tribromo-, 1:3-dibromo-2:4-dinitro-, 2-chloro-1:3-dibromo-, 1-chloro-3-bromo-6-nitro-, and 2-iodo-1:3-dibromo- (Körner and Contard), A., i, 524.
1:2-dibromo-3-nitro- and 1:2-dibromo-4-nitro- (Holleman and Ewus), A., i, 521.
s-m-dibromonitro- and - dichloronitro-, nitration of (Blanksma), A., ii, 147. bromonitroanilino-derivatives, the wandering of bromine in, and their reduction (Orton and Pearson), T., 725; P., 62.
chloro-, freezing-point surfaces of the system, naphthalene, phenol, and (Hirobe), A., ii, 928.
o-chloronitro-, products of the nitration of (V. Ostromisslensky), A., i, 867.
1-chloro-2:4-dinitro-, condensation of, with aminooquinolines (Meigen, Garis, Merkellbach, and Wichern), A., i, 580.
dihalogen derivatives, condensation of, with acetyl and benzoyl chlorides under the influence of aluminium chloride (Boekeken), A., i, 189.
1:2-dihydroxy- See Catechol.
1:3-dihydroxy- See Resorcinol.
1:4-dihydroxy- See Quinol.
1:2:3-trihydroxy- See Pyrogallol.
1:3:5-trihydroxy- See Phloroglucinol.
nitro-, magnetic and electric double refraction of (Cotton and Mouton), A., ii, 745.
action of, on aldehydepheyhydrarzones in the light (Ciusa), A., i, 460.
4:6-dinitro-1:3-diamino-2-cyano- (Blanksma), A., i, 271.
nitroso-, electrolytic production of (Diefennbach), A., i, 409.
Benzeneazoacetamidocyananilide. See Chrysoidine, cyano-, acetyl derivative of.
Benzeneazoaniline. See Azobenzene, p-amino-.
Benzeneazo-1-anthramine and its hydrochloride (Pisovschii), A., i, 481.

Benzeneazo-2- and -4-benzeneazophenols, 4- and 2-, p-nitro- and their acetyl derivatives (Grandmougin and Freimann), A., i, 1023.
Benzeneazo-benzil- and -benzenophenone- p-hydrazones and their hydrochlorides (Tröger and Müller), A., i, 1025.
Benzeneazo-benzoylacetic acid and p-nitro-, and their methyl esters (Wahl and Yoshisaka), A., i, 647.
Benzeneazo-benzylidene-p-hydrazone and its derivatives (Tröger and Müller), A., i, 1025.
Benzeneazo-2:6-dibromoaniline and its coloured salts (Hantzsch and Hilscher), A., i, 485; (Hewitt), A., i, 582.
Benzeneazo-m-bromo-p-cresol, action of mercuric acetate on (Smith and Mitchell), T., 851.
4-Benzeneazo-1-p-bromophenyl-5-methyl-3-pyrazolone (Michaelis and Stieglcr), A., i, 210.
Benzeneazo-o-chlorophenol and its sulphate and benzoate (McPherson and Dubois), A., i, 462.
Benzeneazo-o-cresol, o-nitro- (Borsche), A., i, 66.
4-Benzeneazo-o-cresol, 2:4'-dinitro- (Borsche), A., i, 67.
Benzeneazo-p-cresol, acyl derivatives of, and their transformation products (Auwers and Eckhardt), A., i, 480.
and m-bromo-, action of mercuric acetate on (Smith and Mitchell), T., 851.
and p-chloro-, action of diazomethane on (Smith and Mitchell), T., 846.
mercuri-acetate and -chloride (Smith and Mitchell), T., 851; P., 71.
Benzeneazo-p-cresyl methyl ether, p-chloro- (Smith and Mitchell), T., 846.
Benzeneazoacuminyldene-p-hydrazone and its hydrochloride (Tröger and Müller), A., i, 1025.
Benzeneazo-p-cyanoanilide, benzoyl derivative, melting point of (Pierron), A., i, 925.
Benzeneazo-p-cyano-o-ethoxyanilide, melting point of (Pierron), A., i, 925.
Benzeneazo-3-cyano-β-naphthol-6-sulphonic acid, p-nitro-, sodium salt (Lange), A., i, 300.
Benzeneazo(dimethylanilinium, p-mono- and tri-bromo-, coloured salts of (Hantzsch and Hilscher), A., i, 485.
Benzeneazo-$\beta$-dinaphthylamine and $p$-chloro- (FISCHER and STRAUS), A., i, 222.

4-Benzeneazo-1-3-diphenylpyrazole and its 5-chloro- and 1-$m$-nitro-derivatives (MICHAELIS and WILLERT), A., i, 215.

Benzeneazo-$m$-ethoxyanilide (PIERON), A., i, 925.

Benzeneazoengeny1 ethyl ether, $p$-bromo- (AUWERS), A., i, 229.

Benzeneazofurfurilidene-$p$-hydrazine and its hydrochloride (TROGER and MÜLLER), A., i, 1025.

Benzeneazo-guaiacol and its ethyl ether, and acetyl and $\alpha$-, $m$-, and $p$-nitro-derivatives (COLOMBO and LEONARDI), A., i, 68.

Benzeneazonaphthol and its ethyl ether. See Phthalic anhydride phenylhydrazone.

Benzeneazo-$m$-hydroxybenzoic acid and its methyl ester (GRANDMOUGIN and FREIMANN), A., i, 1024.

Benzeneazo-$p$-hydroxybenzoic acid and ethyl ester, and their acetyl derivatives (GRANDMOUGIN and FREIMANN), A., i, 1024.

Benzeneazo-$m$-hydroxyypyridine (MILLS and WIDDOWS), T., 1378; P., 174.

$\omega$-Benzeneazo-$m$-methoxytoluene, $\omega$-dinitro- (PONZIO and CHARRIER), A., i, 583.

Benzeneazo-$\omega$-naphthol and tetramethyldiaminobenzylidene, constitution of the acetylated condensation products from (Auwers and EISENLOHR), A., i, 229; (MÖHLAU), A., i, 374.

Benzeneazo-$\beta$-naphtol, 2:4:6-tribromo- (ORTON and EVERATT), T., 1020.

$\beta$-Benzeneazo-$\beta$-naphtol, acetyl derivatives of, and their transformation products (Auwers and ECKART), A., i, 480.

Benzeneazo-$\beta$-naphtol, $p$-chloro- (ORTON and EVERATT), T., 1020.

Benzeneazo-$\alpha$-naphthols, $\alpha$- and $\beta$-, action of diazomethane on (SMITH and MITCHELL), T., 845; P., 71.

Benzeneazo-$\omega$-nitrophenol mercuriacetate and -bromide (SMITH and MITCHELL), T., 850.

$\omega$-Benzeneazo-$\omega$-dinitrotoluene (PONZIO), A., i, 483.

Benzeneazo-ornicin, $p$-mono- and $s$-tribromo-(ORTON and EVERATT), T., 1019.

Benzeneazoophenol and its bromo-derivatives, mercuri-salts of (SMITH and MITCHELL), T., 847; P., 71.

action of diazomethane and of mercuric acetate on (SMITH and MITCHELL), T., 845.

Benzeneazo-phenol, benzenesulphonyl ester of, and aminonitro-, and its $N$-acetyl derivative (GRANDMOUGIN and FREIMANN), A., i, 1023.

Benzeneazo-phenol, $o$-nitro- (BORSCH), A., i, 66.

Benzeneazo-$p$-phenol, and its acyl and alky1 derivatives, colour intensity of (GÖRKE, KöPPE, and STAIGER), A., i, 477.

4-Benzeneazo-phenol, 2$':4'$-dinitro- (BORSCH), A., i, 67.

Benzeneazo-$m$-phenylene-dicyanoamide and -dicarbazide (PIERON), A., i, 925.

Benzeneazo-$m$-phenylenetetrachloride-amide, $m$-nitro-, and its hydrochloride (SACHS and APPENZELLER), A., i, 227.

4-Benzeneazo-3-phenyl-$m$-nitrophenyl-5-pyrazolone (MICHAELIS and WILLERT), A., i, 215.

5-Benzeneazo-1-phenyltriazole, 3-thiol- (FROMM and BAUMHAUER), A., i, 702.

5-Benzeneazo-2-pyridone, synthesis and reduction of, and its chloro-derivative (MILLS and WIDDOWS), T., 1372; P., 174.

Benzene-$4$-azoresorcinol, $p$-mono- and $s$-triacetone- and $p$-nitro-, and their salts (ORTON and EVERATT), T., 1017.

Benzeneazo-salicilaldehyde, $o$-nitro-, and its phenylhydrazone (GRANDMOUGIN and FREIMANN), A., i, 1024.

Benzeneazo-salicilic acid, phenyl ester, acetyl derivative of, and $p$-nitro-, esters, and their acetyl derivatives (GRANDMOUGIN and FREIMANN), A., i, 1024.

Benzeneazo-tetramethyl-2:4-diamino-benzaldehyde, $m$-nitro- (SACHS and APPENZELLER), A., i, 188.

Benzeneazo-thymol, $p$-nitro- and 2$':4'$-dinitro- (BORSCH), A., i, 66.

3-Benzeneazo-toluene, 2$':4'$-di- and 4$':2'$-tri-nitro- (BORSCH), A., i, 67.

2$'$-Benzeneazo-toluene-$5'$-arsonic acid, 4-hydroxy-, and its sodium salts (BARRICLIF, PYMAN, and REMFRY), T., 1898.

Benzeneazo-$m$-tolylcarbamide, melting point of (PIERON), A., i, 925.

Benzeneazo-$p$-tolylidene-$p$-hydrazine and its hydrochloride (TROGER and MÜLLER), A., i, 1025.

$\omega$-Benzeneazo-$p$-xylene, $\omega$-dinitro- (PONZIO and CHARRIER), A., i, 582.
5-Benzeneazo-2-xylenol (Auwers and v. Markovits), A., i, 630.

Benzeneazo. See also Phenylazo.

Benzenediazonium salts. See Diazobenzene salts.

Benzenedisulphonylic acids, \( m \)- and \( p \)-ammonium and silver salts (Suzuki), A., i, 871.

Benzenedisulphonimides, \( m \)-, \( p \)-, and \( p \)-bromo- of the \( o \)-imide (Suzuki), A., i, 871.

Benzenedisulphonylhydroxylic acids. See Benzenedisulphonylhydroxylamines.

Benzenedisulphonylhydroxylamines, \( o \)-, \( m \)-, and \( p \)-bromo- of the \( o \)-compound (Suzuki), A., i, 871.

Benzene formula, nature of the (Vidal), A., i, 902.

Benzenehexacarboxylic acid. See Mcllittic acid.

Benzenehydrazo-\( p \)-cresol, acetyl derivatives of (Auwers and Eckardt), A., i, 480.

Benzenehydrazo- \( \text{eugenyl} \) acetate and \( p \)-chloro- (Auwers), A., i, 228.

Benzene nucleus, influences governing orientation in the (Obermiller), A., i, 146.

displacement of alkyloxy-groups in the, by hydrogen (Semmler), A., i, 557.

Benzenepentacarboxylic acid. See Rhizocholic acid.

Benzene rings, formation of (Meerwein), A., i, 89.

Benzenesulphonic acid and \( p \)-bromo- and \( p \)-chloro-, preparation of (Knoevenagel and Kenner), A., i, 971.

Benzenesulphonic acid, alkaloidal salts, and their rotatory power (Hilditch), T., 1621.

Aniline salt (Vallée), A., i, 976.

Benzenesulphinic anhydride and \( p \)-bromo- and \( p \)-iodo-, preparation of (Knoevenagel and Polack), A., i, 971.

Benzenesulphonic acid, study of isomorphous derivatives of (British Association Reports), A., i, 330.

Benzenesulphonic acid, alkaloidal salts, and their rotatory power (Hilditch), T., 1621.

Benzenesulphonyltrytophans (Ellinger and Flamand), A., i, 378.

Benzene-1:2:4-tricarboxylic acid. See Trimellitic acid.

Benzhydrol (diphenylcarbinol), tetra-bromo-\( p \)-dihydroxy- and its triacetate and tetramorphodihydroxy-, and their transformation products (Zincke and Bushchel), A., i, 781.

Benzhydroxyamic acid, transformation of, into anilides (Ponzio and Giovetti), A., i, 726.

Benzhydryl-acetyl- and \( \text{benzoylacetones} \) (Fosse), A., i, 86.

Benzhydrylamine nitrate and sulphate and its acyl derivatives (Busch and Leefhelm), A., i, 152.

Benzhydrylbenzoylacetic acid, ethyl ester (Fosse), A., i, 86.

\( p \)-Benzhydryldiphenyl- \( n \)-napthylmethyl chloride and \( \text{p-} \text{tolylmethyl} \) bromide (Tsichtschirabin), A., i, 872.

Benzhydryltriphenylmethane and its derivatives (Tsichtschirabin), A., i, 624.

\( p \)-Benzhydryltriphenylcarbinol and its ethyl ether, bromide, and chloride (Tsichtschirabin), A., i, 625.

Benziadine (di-\( \text{p-aminodiphenyl} \)), physiological action of (Adler), A., ii, 512.

replacement products of (Neumüller), A., i, 369.

Benzil (\( \text{dibenzoyl} \) ), action of methyl- carbamides on (Biltz, Hörmann, and Rimpel), A., i, 218; (Biltz and Rimpel), A., i, 462.

combination of, with phenol (V. Liebig and Keim), A., ii, 449.

Stannic chloride (Meyer), A., i, 731.

Benzil, \( di- \text{p-bromo-} \) and its diacyl derivative (Biltz and Rimpel), A., i, 574; (Biltz), A., i, 575.

4:3:4’-tetrahydroxy-, and its tetra-benzoyl derivative (Barger and Ewins), T., 737; P., 60.

2:2’-dinitro-, Popović’s (Ekecrantz and Ahlqvist), A., i, 348.

Benzilic acid (diphenylglycollic acid, \( \text{hexamethyleneacetic acid} \)), preparation of (V. Liebig), A., i, 540.

combination of, with amines (V. Liebig), A., i, 646.

Benzilosazone, alkaline reduction of (Schlenk), A., ii, 738.

Benziminoazopiperidine, \( n \)-nitro-, and its dibenzoyl derivative (Spiegel and Kaufmann), A., i, 293.

Benzo-. See also Benz-, Benzoyl-, and under the parent Substance.

Benzonic acid and acetic acid, heat of neutralisation of, by aniline in benzene solution (Vignon and Évieux), A., ii, 604.

esterification of (I. K. and M. A. Phelps and Osborne), A., i, 166.
Benzoic acid, acyl derivatives, preparation of (Heller), A., i, 648.
detection of, in butter (Halkphen), A., ii, 906; (Robin), A., ii, 1078.
and glycine, detection of, in urine (Seo), A., ii, 518.
detection and estimation of, in ketchups, fruits, and ciders (Reed), A., ii, 74.
estimation of, in ketchup (La Wall and Bradshaw), A., ii, 438.
and cinnamic acid, separation of (de Jong), A., ii, 993.

Benzoic acid, brucine and echinonine salts, and their optical activity (Hilditch), T., 1390.
glucinum salt (Tanatar and Kurovski), A., i, 759.
glucinum and zirconium salts (Tanatar and Kurovski), A., i, 166.
lithium salt, compound of, with caffeine (Bergelli), A., i, 1004.

Benzoic acid, alkylaminoalkyl esters, preparation of (Farwberke vorm. Meister, Lucius, & Brüning), A., i, 167.
benzyl ester (Bacon), A., i, 815.
e-bromoamyl and e-bromopropyl esters (Merck), A., i, 419.
ethyl ester, influence of hydrogen bromide and zinc bromide in the formation of (I. K. and M. A. Phelps and Eddy), A., i, 789.
influence of certain chlorides on the formation of (I. K. and M. A. Phelps and Eddy), A., i, 790.
influence of certain sulphates on the formation of (Phelps, Palmer, and Smillie), A., i, 790.

Benzoic acid, o-amino. See Anthranilic acid.
p-amino, and p-nitro, chloroalkyl and alkylaminoalkyl esters of, preparation of (Farwberke vorm. Meister, Lucius, & Brüning), A., i, 638.
3:4-diamino- and 3-nitro-4-amino- chloroethyl and dialkylaminoalkyl esters of, preparation of (Einhorn), A., i, 639.
3:5-diamino-4-hydroxy-, and its hydrochloride and sulphate, and 3:5-dinitro-4-hydroxy-, and its esters (Reverdin), A., i, 537.
bromoimino-m-nitro-, chloroimino-p-bromo-m-nitro-, chloroimino-m-nitro-, and imino-p-nitro-, isomeric esters of (Hilpert), A., i, 830.
bromodinitrodihydroxy-, and its methyl ester and silver salt (Dahse), A., i, 552.

Benzoic acid, hydroxy-derivatives, electrolytic oxidation of (A. G. and F. M. Perkin), T., 1188; P., 149.
copper salts of, and the action of ammonia and pyridine on (Ley and Erler), A., ii, 177.
conductivity of the sodium salts of (Ley and Erler), A., ii, 21.
O-hydroxy-. See Salicylic acid.
m- and p-hydroxy-, azo-derivatives of (Grandmougin and Freimann), A., i, 1024.
methyl esters, compounds of, with phenylcarbimide (Michael and Cobb), A., i, 949.
3:4-dihydroxy-. See Protecatechic acid.
3:4:5-trihydroxy-. See Gallic acid.
imino-, esters of, catalysis of (Derby), A., i, 419; (Stieglitz), A., ii, 167.
2-iodo-4-amino-, and its methyl ester and salts, and N-acetyl derivative, 2-iodo-4-nitro-, and its esters and salts, 2-iodo-4-nitro-, and its methyl ester and salts, 2-iodoxy-4-nitro-, and its salts, and 4-nitro-, 2iodochloride of, and its methyl ester (Wilgerodt and Gartner), A., i, 877.
p-nitro-, e-bromoamyl ester (Merck), A., i, 419.
six dinitro- (Sirks), A., i, 532.
3:5-dinitro-4-hydroxy- (Reverdin and Del Luc), A., i, 168.
m-nitroimino-, methyl ester, catalysis of (Derby), A., i, 419.
o-Benzoisop sulphide ("saccharin"), properties, detection, and estimation of (Parmeggiani), A., i, 267.
detection of, in beverages and foods (Bianchi and di Nola), A., ii, 1079.
detection of, in fatty oils (Bianchi and di Nola), A., ii, 440.

Benzoil, alkylation of (Irwin and McNicol), T., 1604; P., 191.
condensation of, with methyl alcohol (Irwin and McNicol), T., 950; P., 119.
ethyl ether, melting point of (Irwin and McNicol), T., 1601.

Benzoil, m-dibromo- and m-dichloro- (Ekecrantz and Ahlqvist), A., i, 903.
2:2'-dinitro-, Popovici’s (Ekecrantz and Ahlqvist), A., i, 347.
1-Benzoin, preparation of (McKenzie and Wren), T., 309; P., 26.

Benzoil condensation, study of the (Ekecrantz and Ahlqvist), A., i, 991.

84
Benzoinoxime, alkylation of (IRVINE and MOODIE), T., 103.

Benzonitrile, 2:4:6-tri-bromo-, crystallography of (JAEGER), A., i, 988.

Benzophenone, 2-bromo-, crystallography of (JAEGER), A., i, 988.

2:4:6-tri-bromo- (MONTAGNE) A., i, 988.

Crystallography of (JAEGER), A., i, 988.

3:3'-di-bromo-5:5'-dinitro-4:4'-dihydroxy-, and 3:5:3':5'-di-trichloro-4:4'-dihydroxy-, and their diacetates (ZINCKE and BIRSCHEL), A., i, 782.

2:4:2'-4' and 3:4:3':4'-di-trichloro- (BOESKEN), A., i, 189.

2:5-di-hydroxy- (HERZIG and HOFMANN), A., i, 190.

2-iodo-4-nitro-, and its oxime (WILLGERODT and GARTNER), A., i, 877.

thio- (BILLMANN), A., i, 143.

Benzophenoneoxime, spontaneous transformation of (KONOWALOFF and MÜLLER), A., i, 277.

o-Benzoquinhydrone, octachloro-, and its reactions (JACKSON and CARLETON), A., i, 427.

Benzquinone hydro-gren persulphide (BRUNNER and VIUIILLEUMIER), A., i, 900.

Benzquinone, tri- and tetra-chloro-, formation of, from 2:4:6-trichlorophenol (LIEBER), A., i, 335.

o-Benzoquinone, two forms of (WILLSTÄTTER and MÜLLER), A., i, 731.

o-Benzoquinone, tri-chloro-, derivatives of (JACKSON and CARLETON), A., i, 427.

m-Benzoquinone (resoquinone), tribromo- (MEYER and DESAMARI), A., i, 658.

p-Benzoquinone, constitution of (HARTLEY), P., 285.

Absorption spectra of, in a state of vapour and in solution (HARTLEY and LEONARD), P., 284.

Metallic haloids (MEYER), A., i, 731.

p-Benzoquinone, tri-bromo-hydroxy- (JACKSON and FLINT), A., i, 191.

tetrachloro- (chloroanil), preparation and purification of (BOUVEAULT), A., i, 190.

Benzoquinoneanil, bromo-derivatives (SMITH and ORTON), T., 318; P., 27.

Benzoquinonebenzoylphenylhydrazone, chloro- (MCPHERSON and DUBOIS), A., i, 462.

Benzoquinoneoximecarboxylic acid (HOUBEN and BRASSERT), A., i, 27.

o-Benzoquinonesulphonic acid, phenylhydrazone of (SCHULTZ and ICHEN-HEUSER), A., i, 230.

Benzosalin. See o-Benzoyloxybenzoic acid, methyl ester.

1.2-3-Benzotriazole, 6-amino-1-hydroxy-, and its hydrochloride and acetyl derivatives, and 6-nitro-1-hydroxy-, and its metallic and amine salts, ethers, and acyl derivatives (CURTIUS and MAYER), A., i, 53.

6-nitro-1-hydroxy- (CURTIUS and MAYER), A., i, 53; (SPIEGEL), A., i, 363.

Benzoxy-. See Benzoxyloxy-.

Benzoyl. See also Benz-, Benz-, and under the parent Substance.

Benzoyl chloride, 2:4:6-tri-bromo-, crystallography of (JAEGER), A., i, 988.

2-iido-4-nitro- (WILLGERODT and GARTNER), A., i, 877.

Benzoyl peroxyde, colour test for (GOLDETZ), A., ii, 330.

Benzoylacetic acid, esters, preparation of, and nitroso-, methyl ester of (WAHL and YOSHISAKA), A., i, 647.

Benzoylacetylasetone and the action of phenylhydrazine on (RUHEMMANN), T., 1283; P., 178.

γ-Benzoyl-a-acetyl-β-diphenylbutyric acid, ethyl ester, transformation of, into a cyclic keto-alcohol (RABE and EHRENSTEIN), A., i, 553.

Benzoylacrylic acid, preparation of (BOUGAULT), A., i, 179, 269.

fixation of acetoephene (BOUGAULT), A., i, 796.

Fixation of hydrogen cyanide by (BOUGAULT), A., i, 422.

Benzoylacrylic benzolic, benzoylpropionic, cinnamic, and phenylacetic anhydrades (BOUGAULT), A., i, 791.

Benzoylgiacric acid, methyl ester (THOMS and VOGELSANG), A., i, 4.

Benzoylampyralino-alcohols, preparation of (FAHRWERKE VOM. MEISTER, LUCIUS, & BRÜNING), A., i, 167.

Benzoylisoamine (BUSCH and LEEME-L), A., i, 153.

Benzoylamino-. See under the parent Substance.

4-Benzoylanilopyrine and its phenylhydrazone and methiodide and 4-Benzoyl-α-anilopyrine (MICHAELIS and ENGELHARDT), A., i, 919.

Benzoylanthrancilic acid, brucine and cinchonine salts, and their optical activity (HILDITCH), T., 1391; P., 186.

4-Benzoylantrypyrine and its oxime and hydrazones (MICHAELIS and ENGELHARDT), A., i, 918.
Benzoylation, rule in, of aromatic hydroxy-acids and their esters (Lassar-Cohn and Löwenstein), A., i, 984.
of aminohydroxy- and diamino-acids (Sörensen and Andersen), A., i, 651.

2-Benzoylbenzoic acid, 5-amino-, and its silver salt, and 5-nitro-, and its esters, silver salt, and chloride (Rainer), A., i, 648.
4- and 5-nitro-derivatives (Rainer), A., i, 539, 647.

4-Benzoylbenzoic acid, 2'-nitro- (Kliegl), A., i, 550.

Benzoylbenzoic acids, action of aniline on (Meyer), A., i, 25.

γ-Benzylal-α-isobutyryl-β-phenylbutyric acid, ethyl ester (Dieckmann and Kron), A., i, 389.

Benzoylcarbinol, m-nitro-, and its oxidation (Evans and Brooks), A., i, 338.

1-Benzoylcumarone, p-hydroxy-, and its acetate (Zwayer and V. Kostanecki), A., i, 444.

Benzoyldiglycinimide (Bergell and Feigl), A., i, 140.

5-Benzyl-1:3-diphenylbarbituric acid, 5-bromo-, preparation of, and the estimation of bromine in (Whiteley), P., 288.

α-Benzylal-α-β-diphenylpropiionic acid, and its methyl ester (Reimer and Reynolds), A., i, 889.

α-Benzylal-ββ-diphenylthiocarbamide (Dixon and Taylor), T., 693; P., 74.

Benzoylenebarbamide. See 2:4-Dioxo-1:3-quinazoline.

Benzoylformamidoxime (Dielis and Pillow), A., i, 535.

Benzoylformic acid, velocity of esterification of, by means of alcoholic hydrogen chloride (Kailan), A., ii, 28.

Benzoylhydrazide, action of sodium hypochlorite on (Darapsky), A., i, 106.

4-Benzoyliminopryrine (Michaelis and Englandhart), A., i, 919.

Benzoyl lactamidine (Einhorn), A., i, 611.

4-Benzoyl-1-methylandino-1-phenyl-3-methylpyrazole. See 4-Benzoyl-phenylpyrazole.

β-Benzylal-α-1-methyl-γ-4-cyclohexene-propionic acid, ethyl ester (Harding, Haworth, and Perkin), T., 1966.

α-Benzylal-2:4-dimethylphenylhydrazide (Curtil and Mayer), A., i, 53.

Benzoyloxybenzene-β-sulphonic acid, ethyl ester (Lassar-Cohn and Löwenstein), A., i, 985.

α-Benzoyloxybenzoic acid (benzoylalicylic acid) and its ethyl ester (Lassar-Cohn and Löwenstein), A., i, 985.
brucine and cinchonine salts, and their optical activity (Hilditch), T., 1931; P., 186.
methyl ester (benzosalin), therapeutic value of (Varanini), A., ii, 520.

Benzoyloxydiphenylamine, bromo-derivatives (Smith and Orton), T., 318; P., 27.

Benzoyloxyethylamine, p-amino-, and its hydrochloride, picate, and dibenzoyl derivative (Forster and Fierz), T., 1869; P., 227.

β-Benzoyloxy-β-3:4-methylenedioxyphenylethylidimethylamine and its additive salts and physiological action (Pyman), T., 1796; P., 208.

β-Benzoyloxyanaphthoic acid, ethyl ester (Lassar-Cohn and Löwenstein), A., i, 985.

α-Benzoyloxyalicylic anhydride (Farbenfabriken Vorm. F. Bayer & Co.), A., i, 984.

Benzoylphenylbutyramide (Busch and Leefhelm), A., i, 152.

α-Benzoylphenylhydrazine, action of, on halogen derivatives of quinones (McPherson and Dubois), A., i, 401.

α-Benzylal-phenylhydrazine, α-nitro-β-nitros- (Ponzio), A., i, 483; (Ponzio and Charriere), A., i, 522.

4-Benzylal-1-phenyl-2-methylidihydropyrazole, 2:5-imino-.- See 4-Benzoyliminopryrine.

4-Benzylal-1-phenyl-3-methylpyrazole, 5-amino-, methiodide and methochloride of, and 5-chloro-, methiodide of (Michaelis and Englandhart), A., i, 918.

5-thiol-, and its alkyl and acyl ethers (Michaelis and Lehmann), A., i, 691.

4-Benzylal-1-phenyl-3-methylpyrazole-5-sulphonic acid (Michaelis and Lehmann), A., i, 691.

4-Benzylal-1-phenyl-3-methylpyrazole-one, preparation and isomeric modifications of (Michaelis and Englandhart), A., i, 918.

4-Benzylal-1-phenyl-3-methylpyrazole-one, 5-thio-, and its derivatives (Michaelis and Lehmann), A., i, 690.

β-Benzoylpropionic acid, α-cyano- (Boucalt), A., i, 422.
INDEX OF SUBJECTS.

4-Benzoylquinoline. See Phenyl γ-
quinonyl ketone.

Benzylosalicylic acid. See α-Benzoyl-
oxybenzoic acid.

Benzylosemicarbazide, preparation and
reactions of (Daratsky), A., i, 106.

β-Benzylisouccinic acid. See α-Carb-
oxy-β-benzoylpropionic acid.

Benzyloctetramethylidiaminopentanol
hydrochloride. See Alypine.

Benzylothiocarbimide.

Benzoyltetramethylidiaminopentanol
hydrochloride. See Alypine.

Benzoylthiourea, preparation and reac-
tions of (Dixon and Taylor), T., 692; P.,
74.

4-Benzoylthiopyrine and its phenyl-
hydrazone and methiodide (Michaelis
and Engelhardt), A., i, 918.

4-Benzoyl-γ-thiopyrine (Michaelis and
Lehmann), A., i, 691; (Michaelis
and Engelhardt), A., i, 919.

α-Benzoyltripheny lacetic acid and its
sodium salt (Kohler), A., i, 778.

3-Benzoyl-2:4:6-triphenyl-Δ3-cyclo-
hexene-1:1-dicarboxylic acid, ethyl
ester (Dieckmann and Kron), A., i,
389.

2-Benzoylxanthene and its leuco-deriva-
tive (Heller and v. Kostanecki), A.,
i, 445.

2-Benzoylxanthone (Heller and v.
Kostanecki), A., i, 445.

Benzylic alcohol, preparation of (Meisen-
heimer), A., i, 417.

reduction of, in presence of iron
(Ipatiev), A., i, 347.

Benzylic alcohol, α-nitroso-, preparation
of (Kalle & Co.), A., i, 786.

preparation of a compound having the
composition of (Kalle & Co.),
A., i, 980.

Benzylic arsenite, preparation of (Lang,
Mackey, and Gortner), T., 1370; P.,
151.

bromide, 3:5-dibromo-(Wheeler and
Clapp), A., i, 597.

dibromo-p-hydroxy-, condensation
products of, with aromatic bases
(Auwers and Dombrowski), A.,
i, 383.

p-nitro-, interaction of, with iso-
nitrosoaniline in presence of
silver oxide (Forster and
Holmes), T., 250; P., 9.

chloride, p-nitro-, interaction of,
with isonitrosoaniline in presence of
sodium ethoxide (Forster and
Holmes), T., 248; P., 8.

ο- and p-nitro, condensation of,
with acetylaceton (Mehl), A., i,
655.

cyanide. See Phenylacetonitrile.

ether, αα-dichloro-2:2'-dinitro-
(Kliegl), A., i, 82.

methyl ether (Bacon), A., i, 815.

Benzylic disulphide, isomerism of (Hins-
berg), A., i, 257.

sodium thiosulphates, o-, m-, and p-
nitro-, and the action of alkalis on
(Price and Twiss), T., 1403; P.,
185.
sulphoxide, a possible example of
dynamic isomerism (Smythe), P.,
285.

Benzylic acid, 3:5-dibromoaminoo-
N-phthalaldehyde derivative of
(Wheeler and Clapp), A., i, 898.

α-Benzylacetone, α-amino-, and its
additive salts (SonN), A., i, 55.

Benzylic acetonaphenylhydrazone
(Schlenk), A., i, 738.

N-Benzylidoxime, molecular rearrange-
ment of (Kuhara), A., i, 900.

Benzylic aminoacetal and analogues
(Rüg-
heimer and Schöln), A., i, 153.

4-Benzylaminotoluene, 3:5-dinitro-, pre-
paration of (Ullmann), A., i, 627.

Benzylicamines, alkylated, derivatives of
(Gnehm and Schönholzer), A., i,
112.

Benzylic aminopyrines, 2- and ψ-,
and their derivatives (Michaelis,
Mielecke, and Lutze), A., i, 62.

4-Benzylantipyrine, α-hydroxy-
(Michaelis and Engelhardt), A.,
i, 918.

Benzylicarzine and its platinichloride
(Dehn and Williams), A., i, 721.

1-Benzylbenzoylcarzolone and its addi-
tive salts (Millath), A., i, 1014.

β-Benzyl-α-butyl alcohol and its acetate
(Guerbet), A., i, 636.

β-Benzylisobutylcarbinol and its acetate
(Guerbet), A., i, 636.

Benzylicchloro-isopropyl alcohol (Four-
neau and Tiffenau), A., i, 163.

Benzylicchlorosilane (Melzer), A., i,
967.

N-Benzylidacetonitrile (v. Meyer and
Schumacher), A., i, 909.

Benzylichrohydroxime, p-5-dinitro-
hydroxy- (Johnson and Derby), A.,
i, 1019.

3-Benzyl-4:7-dimethylcoumarin
(Fries and Klotermann), A., i, 822.

5-Benzylethylamino-2-benzenazo-
phenetole, -phenol, and -4-p-toluene-
azophenol (Bülow and Sproesser),
A., i, 583.

5-Benzylethylamino-2:4-bis-benzenazo-
phenol and -4-p-tolueneazophenol
(Bülow and Sproesser), A., i, 583.

7-Benzylethylamino-4-mono- and -3:4-
dimethylcoumarins (Bülow and
Sproesser), A., i, 272.

5-Benzylethylamino-2-naphthalene-
azophenol (Bülow and Sproesser),
A., i, 588.
Benzylethyl-m-aminophenol, preparation of, and its salts and ethyl ether, and condensation of, with esters of 1:3-ketocarboxylic acids (Bülow and Sprenger), A., i, 272.

primary bisazo-compounds of (Bülow and Sprenger), A., i, 583.

5-Benzylethylamino-2-p-sulphobenzeneazophenol and 2-p-tolueneazophenol (Bülow and Sprenger), A., i, 583.

Benzylethylaniline, m-amin-o, acetyl derivative of, and p-hydroxy- (Gnëhm and Schönholzer), A., i, 112.

Benzylethylaminesulphonic acid and its salts and nitroso-derivative (Gnëhm and Schönholzer), A., i, 112.

Benzylethylisobutylsilicicol and its chlorides and oxide, synthesis of (Luff and Kipping), T., 2006; P., 224.

Benzylethyldipropylsilicicolene and its sulphonation (Marsden and Kipping), T., 198; P., 12.

as-Benzylethyl-p-phenylenediamine, sulphate of (Gnëhm and Schönholzer), A., i, 112.

a-Benzyl-1-ethyl-2- and 3-pipercolinium salts (Scholtz), A., i, 679.

Benzy1ethylpropylsilicicol oxide and its sulphonation (Marsden and Kipping), T., 138; P., 12.

Benzy1ethylsilicon dichloride, preparation of (Luff and Kipping), T., 2005.

Benzy1ethylsilicone (Robison and Kipping), T., 439; P., 25.

Benzy1glycoside (Blanksm and Abeready van EKenstein), A., i, 952.

9-Benzylhexahydroanthracene, preparation of (Godchot), A., i, 16.

Benzy1hydrazine, action of nitrous esters on, in alkaline solution (Stolle), A., i, 917.

β-Benzylhydroxylamine, interaction of, with ketones (Scheiber), A., i, 763; (Scheiber and Brandt), A., i, 764.

Benzy1ideneacetone and its hydrochlorides (Francesconi and Cusmano), A., i, 803.

aminopyprylidene derivatives from (Kohn), A., i, 829.

Benzy1ideneacetophenone, 2-hydroxy-, action of hydrochloric acid on (Perkin, Robinson, and Turner), T., 1110.

Benzy1idene-α-amin-o, action of magnesium organic compounds on (Busch and Leefheim), A., i, 153.

Benzy1ideneaminoo-alky1cinnamv acids, substituted, esters, relation between constitution and capacity for forming liquid crystals (Völländer and Kästen), A., i, 641.

p-Benzylideneaminodimethylamline and its hydrochlorides (Moore and Gale), A., i, 369.

Benzy1idene-1-amino-β-naphthol, p-nitro-, hydrochloride of (Pope and Fleming), T., 1918.

Benzy1idene-4-amino-o-naphthol, p-nitro- (Pope), T., 536.

Benzy1idene-p-aminophenol hydrochloride and o- and p-nitro-, and their hydrochlorides (Pope and Fleming), T., 1915.

Benzy1idene-o- and -p-aminophenols, and m- and p-nitro- (Pope), T., 533; P., 24.

Benzy1idene-p-aminophenylarsenic acid, p-hydroxy- (Kuratorium der Georg & Franziska Speyerschen Studienstiftung), A., i, 747.

Benzy1idene-5-aminosalicylic acid, p-nitro- (Pope), T., 534.

Benzy1ideneaniline, o-hydroxy-, and its m'- and p'-nitro-derivatives (Pope), T., 535; P., 24.

trihydroxy- (Gattermann), A., i, 31.

Benzy1idene-o-ansidine, p-nitro-, and its hydrochloride (Pope and Fleming), T., 1917.

Benzy1idene-p-aminisidine hydrochloride and p-nitro-, and its hydrochloride (Pope and Fleming), T., 1915.

Benzy1idene-dicarbamidoxime and its nitro-derivatives (Conduché), A., i, 155.

Benzy1ideneaminocinnamylideneacetone and its hydrochlorides (Francesconi and Cusmano), A., i, 802.

Benzy1idenedimalonic acid and o-nitro-, methyl esters (Meerwein), A., i, 546.

Benzy1idenedimethylhydrazine, benzyol derivative of (Michaelis and Hadanck), A., i, 1020.

Benzy1idenedimethyl isopropyl ketone, reactions of, and its dibromide (Dieckmann and Kron), A., i, 389.

Benzy1idenedimethylsemicarbazide (Michaelis and Hadanck), A., i, 1020.

Benzy1idenedimethylsticol and its phenylhydrzone (Winzheim), A., i, 805.

Benzy1idene-α-naphthylamline, o-hydroxy-, and its hydrochloride (Pope and Fleming), T., 1916.

Benzy1idene-β-naphthylamline, action of ethyl oxalacetate on (Simon and Mauquin), A., i, 296.

Benzylideneacetone hydrochloride (FRANCESCONI and CUSMANO), A., i, 803.

Benzylidenequinone, tetra(bromohydrroxy- and tetrochlorohydrroxy- (ZINCK and BIRSCHL), A., i, 782.

Benzylidenepiperonylideneacetone and its hydrochloride (PAULY and RICHTER), A., i, 286.

Benzylmalonic acid, 3:5-dibromoamino-, N′-phthalyl-derivative (WHEELER and CLAPP), A., i, 898.

Benzylmethylandaniline, m-amino-, and its acetyl derivative, p-hydroxy-, and m-nitro- (GNEHM and SCHÖNHOLZER), A., i, 113.

Benzylmethylandanilinesulphonic acid and its salts and nitroso-derivative (GNEHM and SCHÖNHOLZER), A., i, 113.

1-Benzyl-2-methylbenzopyrazolone (MILLRATH), A., i, 1014.

Benzylmethyglyoxaline, 4:5- or 5:4-, and its additive salts and mercaptan (SONN), A., i, 56.

Benzylmethylene-p-nitrosoaniline and its hydrochloride (GNEHM and SCHÖNHOLZER), A., i, 112.

3-Benzyl-methyl-1-methyluracil (Johson and DERBY), A., i, 1019.

3-Benzyl-1-methyluracil and 5-bromo- (Johson and DERBY), A., i, 1018.

Benzylxybenzene-p-sulphonic acid, sodium salt (SCHULTZ and ICHENHÄUSER), A., i, 230.

Benzyl 3-phenyl-β-benzyl-γ-benzyldenepropyl ketone (REIMER and REYNOLDS), A., i, 989.

Benzylphosphonic acid, hydroxy-, aniline salt (VALLÉE), A., i, 976.

Benzylphthalimide, 3:5-dibromo- (WHEELER and CLAPP), A., i, 898.

a-Benzylpropionic acid, ethyl ester (DIECKMANN and KRON), A., i, 389.

3-Benzylrhodanic acid and its condensation with aldehydes (ANDREASCH), A., i, 683.

Benzylsulphonyl bromide (FROMM and GAUPP), A., i, 970.

Benzyltheophylline and its additive salts (SCHWARZ), A., i, 46.

Benzylsothioanilinocyanomalonic acid, ethyl ester (RUHEMANN), T., 627.

Benzylsulphonic acid, diethyl ester (RUHEMANN), T., 625; T., 53.

Benzylthymines, 1- and 3- (JOHNSON and DERBY), A., i, 1019.

1-Benzyluracil (JOHNSON and DERBY), A., i, 1018.

3-Benzyluracil and 3-bromo- and p-5-dinitro- (JOHNSON and DERBY), A., i, 1018.

Benzylvaleric acid and its salts, ethyl ester, chloride, and amide (GUERRIET), A., i, 636.

2-Benzylxanthen (HELLER and V. KOSTANEC), A., i, 445.

Beryllium. See Glucinium.

Beryl, chemical structure of (VERNADSKY), A., ii, 955.

Betaine, chemical structure of and its amide and chloride (V. BRAUN), A., i, 608.

Betaine, chemical structure of and its amides (V. BRAUN), A., i, 607.

Betaines, new, of the pyridine series (KIRPAL), A., i, 679.

Beukoss Boss. See Lippia scaberrima.

Beverages, detection of "saccharin" and other artificial sweetening materials in (BIANCHI and Di NOLA), A., ii, 1079.

Bile, absorption spectra of (PIETTRE), A., ii, 408.

Bile acids, alleged formation of, by the action of trypsin on haemoglobin (HOLLIS), A., ii, 408.

Bile acids, alleged formation of, by the action of trypsin on haemoglobin (HOLLIS), A., ii, 408.

Bile acids, new reaction for (JOLES), A., ii, 998.

Bile acids, colour reactions of (FLEIG), A., ii, 994.

Bile acids, colour reaction of, with vanillin and sulphuric acid (INUOE and ITO), A., ii, 999.

Bile, ox. See Ox-bile.

Bile, index of subjects, reasons of the increased rate of, in concentrated salt solutions (BAYER), A., ii, 969.

Bile pigments, alleged formation of, by the action of trypsin on haemoglobin (HOLLIS), A., ii, 408.

Bile pigments, spectra of (PIETTRE), A., ii, 408.

Bile salts, behaviour of lecithin with (LONG and GEPHART), A., ii, 872.

Bile salts, behaviour of lecithin with (LONG and GEPHART), A., ii, 872.
INDEX OF SUBJECTS.

1263

Biochemistry, colour reactions in (STEENSMA), A., ii, 442.

Biological importance, oxidations of (V. EULER and BOLIN), A., ii, 1021.

Birch leaf oil (HAENSEL), A., i, 665.

Birds, leucoprotease and anti-leucoprotease of (OPIE and BARKER), A., ii, 117.

Brain of. See Brain.

Liver of. See Liver.

Muscle of. See Muscle.

Bis-p-acetylamino phenylarsinic acid and its sodium salt (PYMAN and REYNOLDS), T., 1185; P., 144.

Bis-2-acetylamino tolyl-5-arsinic acid and its sodium salt (PYMAN and REYNOLDS), T., 1183; P., 143.

Bis 4-amino 2:5-dimethylphenylacetic acid and its derivatives (HELLER and LEYDEN), A., i, 218.

s-Bis-m-aminophenylaminoethane and its tetracetyl derivative (BORSCH and FITSINGI), A., i, 104.

Bis-p-aminophenylarsinic acid and its sodium and barium salts (PYMAN and REYNOLDS), T., 1184; P., 144.

Bis 2-aminotolyl-5-arsinic acid and its sodium salt (PYMAN and REYNOLDS), T., 1181; P., 143.

Bisanhydrophenacylamide and its additive salts and benzoyl and benzylidene derivatives (GABRIEL and LIECK), A., i, 465.

Bisazo-compounds (DUVAL), A., i, 706.

Bisazo-diphenylmethane and 4:4'-dimino- and their 4:4'-diacetyl derivatives, and 4:4'-dicyano- (DUVAL), A., i, 706.

Bisazo-diphenylmethane 4:4'-dicarboxylic acid (DUVAL), A., i, 706.

Bisazo-dyes from phenol and cresols (SCHULTZ and ICHENHAEUSER), A., i, 229.

Bisbenzeneazo-m-hydroxybenzoic acids, a- and ß- and the methyl ester of the ß-acid (GRANDMOUGIN and FREIMANN), A., i, 1024.

Bisbenzeneazophenol, acetyl derivative and benzene sulphonyl ester (GRANDMOUGIN and FREIMANN), A., i, 1023.

Bisbenzeneazosalicylic acid, methyl ester, and its acetyl derivative (GRANDMOUGIN and FREIMANN), A., i, 1024.

Bisbenzoyl cyanide and its derivatives (DIELS and PILLOW), A., i, 535.

Biscyanodimethylaminophenylmethane and its dicarboxylic acid (V. BRAUN), A., i, 628.

Bis 1-cyano 2-hydroxyindene and its salts (MOORE and THORPE), T., 178.

Bisdiazoacetic acid, ethyl ester, action of hydrazine hydrate on, and its salts (CURTIUS and RIMELE), A., i, 921.

Bisdiazoacetic acid, ethyl ester, hydrazide, and its acetyl and aldehyde derivatives, and methyl ester (CURTIUS and RIMELE), A., i, 921.

Bisdiethylmalonyl tetraacetoaminethane (EINHORN and v. DIESBACH), A., i, 110; (EINHORN), A., i, 315.

2:4-Bisdimethylaminophenyl £-cyano 4'-nitrophenylazomethine (SACHS and APPENZELLER), A., i, 227.

Bisdimethylisoxazylcarbinol, imino- (RIEDEL), A., i, 251.

Bisdimethylethylcarbinol, imino-, and its hydrochloride (RIEDEL), A., i, 251.

Bishydroxypridylcarbamide (MILLS AND WIDDOWS), T., 1582; P., 174.

ß-Bisketo-2-phenylbenzotriazine (PIERRON), A., i, 925.

Bis-p-methoxytriazine acid (BOUGAULT), A., i, 341.

Bismethyloami nothiotoxiccarbamide (MICHAELIS and HADANCK), A., i, 1020.

Bismethylcarbamidothiocarbamide (MICHAELIS and HADANCK), A., i, 1020.

4:4'-Bismethylhydrazinophenylmethane. See Diphenylmethanedicarbomethyldiazine.

Bismuth, atomic weight of (GUTHIER and BIRKENBACH), A., ii, 600.

so-called amorphous (COHEN and OLE), A., ii, 199.

and arsenic, freezing-point diagrams of the system (FRIEDRICH and LEBOUX), A., ii, 300.

equilibrium in the system nickel and (POTREVIN), A., ii, 45.

reaction of, with nitric acid (STANSBIE), A., ii, 497.

Bismuth alloys with antimony, hardness of (SAPSCHNIKOFF), A., ii, 600.

with calcium (DONSKI), A., ii, 280.

with cobalt (LEWKONJA), A., ii, 853.

with nickel (VOS), A., ii, 195.

Bismuth compounds, with fatty hydroxy acids (TELLE), A., i, 851.

Bismuth salt solutions, electrolysis of (GUTHIER, BIRKENBACH, and BÜNZ), A., ii, 600.

Bismuth bromide and chloride, melting-point curves of (EGON), A., ii, 1043.

fluorides and oxides of quinquevalent (RUFF, Knoch, and ZEDNER), A., ii, 298.

subnitrate (BROWN), A., ii, 391.

nitrite poisoning after the internal administration of (BÖHME), A., ii, 55.

oxides of quinquevalent (GUTHIER and MICHELER), A., ii, 701.
Bismuth oxide, preparation of (Gutbier and Birkpenbach), A., ii, 600.

velocity of reduction of, by carbon monoxide, and the existence of the suboxide (Brissler), T., 154.

selenide, and antimony and arsenic selenides, compounds of, with silver selenide (Pélabon), A., ii, 587.

telluride (Pélabon), A., ii, 687.

Bismuthous bromide, chloride, and iodide (Herz and Guttmann), A., ii, 199; (Éggink), A., ii, 1043.

Bismuth, estimation of small quantities of (Rowell), A., ii, 325.

estimation of, electrolytically (Metzger and Beans), A., ii, 541; (Feset), A., ii, 780.

estimation of, volumetrically (Éhrenfeld), A., ii, 72; (Balavoine), A., ii, 990.

estimation of, in alloys and slags (Namias), A., ii, 326.

Bismuth ion, bivalent, existence in aqueous solutions of a (Denham), T., 833; P., 76.

Bismuthous bromide, chloride, and iodide. See under Bismuth.

4:4'-Bis-o-nitrobenzeneazoazoxybenzene (Borsche), A., i, 67.

Bis-o-nitrobenzeneazo-o-cresol (Borsche), A., i, 66.

2:4-Bis-o-nitrobenzenoazaphenol (Borsche), A., i, 66.

s-Bis-m-and p-nitrophenylnamioethanes (Borsche and Titsingh), A., i, 104.

Bis-2:4:6-trinitrophenyl-p-phenylenediamine (Morgan and Micklethwait), T., 609.

Bis-m-and p-nitrosocetamidines (Cain), T., 682.

2:3'-Bisoxothyphosphaphthen (2:3-bisethio- naphtenemimidogelin) (Friedländer), A., i, 673.

Bisphenylmethylcarbinol, imino (Riedel), A., i, 251.

Bisphenylmalononitrile and its silver salt and alkyl derivatives (Hessler), A., i, 182.

s-Bistetrahydroquinolylpentamethylenediamine and its piperate (V. Braun), A., i, 678.

Bis-o-thioacetophenone (Farwerke vorm. Meister, Lucius, & Bruning), A., i, 987.

Bis-5-thio-1-phenyl-3-methylpyrazolone and its methiodide (Michaelis and Pander), A., i, 690.

Bis-o-, m-, and p-tolueneazosalicylic acids (Grandmougin and Freimann), A., i, 1024.

Bistriazoaetic acid, ethylester (Forster, Fierz, and Joshua), T., 1073; P., 102.

1,2-Bistriazaethene and the action of magnesium phenyl bromide on (Forster, Fierz, and Joshua), T., 1071; P., 102.

Bityrite occurring with tourmaline in Madagascar (Lacroix), A., ii, 705.

Biurets, 6thio-, new, and their derivatives (Fromm and Weller), A., i, 703.

Blackberry-seed oil (Králzán), A., ii, 239.

Bludite from Chile (Palache and Warren), A., ii, 1047.

regulation of the physico-chemical properties of, after injection of different solutions (Buglia), A., ii, 955.

alkalescence and acidosis of (Landau), A., ii, 304.

influence of alkalis on the alkalescence of normal, and of blood in cases of endogenous acidosis (Landau), A., ii, 304.

coagulation, decomposition of blood platelets, and muscle coagulation (Bürker), A., ii, 510.

influence of alkaline ferro- and ferricyanides on the coagulation of (Larguier des Bancels), A., ii, 955.

coagulation, influence of intestinal extract on (Czubalski), A., ii, 304.

coagulation time (Golla), A., ii, 766.

fatty degeneration in (Shattuck and Dudgeon), A., ii, 958.

issuing from the dog's suprarenal (Young and Lehmann), A., ii, 767.

increase in osmotic concentration of the, during anaesthesia (Carlson and Luckhardt), A., ii, 304.

spectrophotographic investigations on the action of hydrocyanic acid on (Levin), A., ii, 1048.

action of oxidising salts on (Cushny), A., ii, 1049.

albumose in (Abderhalden), A., ii, 605.

amount of albumose in (Freund), A., ii, 117, 512; (Abderhalden), A., ii, 305.
Blood, nature of the combination of gases in, and its constituents (Ostwald), A., ii, 509; (Findlay and Harry), A., ii, 1024.

heats of solution of gases in (Camis), A., ii, 1047.
glycine in normal (Bingel), A., ii, 1048.

the residual nitrogen of (Hohlweg and Meyer), A., ii, 707.
poisonous substances in (Leffmann), A., ii, 522.
proteic acids in (Browniski), A., ii, 205.

occurrence of proteosein (Borchardt), A., ii, 957.
proteases in (Freund), A., ii, 117; (Abderhalden), A., ii, 305.
sugar in (Rona and Michaelis), A., ii, 117; (Michaelis and Rona), A., ii, 329.

the total sugar of (Lepine and Boulud), A., ii, 957.

sugar of, behaviour of, after bleeding (Andersson), A., ii, 767.
detection of (Buckmaster), A., ii, 643.

reaction of, after intravenous injection of acid and alkali (Van Westenrck), A., ii, 1048.

the guanacum reaction of (Senter), A., ii, 305; (Altsberg), A., ii, 999.
estimation of catalases and oxydases in (Löb and Mulzer), A., ii, 958; (Löb), A., ii, 999.

human, estimation of gases in, by the chemical method (Bancroft and Morawitz), A., ii, 319.
estimation of the respiratory capacity of small quantities of (Dreser), A., ii, 1048.
estimation of sugar in (Bang), A., ii, 235.

Blood corpuscles, red, of the ox, behaviour of certain polypeptides towards (Abderhalden and Manwaring), A., ii, 510.

Blood-disk, lysingen of (Takaki), A., ii, 512.

Blood gases, effect of birudin on (Barcroft and Mines), A., ii, 117.

Blood pigment (Marchlewski and Rettinger), A., i, 2022; (Marchlewski), A., i, 843.

Blood pigments, action of certain oxidising agents on (MacWilliam), A., i, 585.

Blood plasma of oxen, behaviour of certain polypeptides towards (Abderhalden and Mclester), A., ii, 511.

Blood platelets, decomposition of, blood coagulation, and muscle coagulation (Bürker), A., ii, 510.

of the ox, behaviour of certain polypeptides towards (Abderhalden and Manwaring), A., ii, 510.

Blood pressure, duration of effect of pituitary extract on (Mummery and Symes), A., ii, 767.

Blood-serum, hemosozic value of (McCay), A., ii, 403.

action of resorbed salicylic acid in (Jacob), A., ii, 512.

of different marine and terrestrial animals, viscosity of (Bottazzi), A., ii, 869.

variations of electrical conductivity, viscosity, and surface tension of, during dialysis (Bottazzi, Buglia, and Jappelli), A., ii, 870.

of various animals, content of protein nitrogen in the (Bottazzi), A., ii, 869.

See also Serum.

Boat funnel. See Funnel.

Body, animal, are there reducing ferments in the? (Hefftner), A., ii, 1054.

Boiling point method, sources of error in the, and attempts to remove them (Beckmann, Lischke, and Klopper), A., ii, 663; (Beckmann), A., ii, 1014.

Boiling points and freezing points of concentrated aqueous solutions and the question of the hydration of the solute (Johnston), A., ii, 661.

and melting points of aromatic sulphides, sclerides, and tellurides, and their halogen additive compounds (Lyons and Bush), A., i, 417.

Boletus edulis, preparation of pure chitin from (Scholl), A., ii, 1065.
Bom, Berthelot-Mahler, modification of the platinum vessel of the (Tóth), A., ii, 664.

Bombycicostero! from chrysalidene oil (Menozzi and Moreschi), A., i, 241.

Bombycx Mori, and its esters and dibromo-derivative from the chrysalis of Bombyx Mori (Menozzi and Moreschi), A., i, 265.

Bone, influence of strontium on the growth and composition of (Storlitzner), A., ii, 769.

Bone dust, manuring with (Uchiyama), A., ii, 128.

Bone marrow, chemistry of (NerKING), A., ii, 516.

Bone phosphates, behaviour of, in soil (Montanari), A., ii, 128.

Boric acid and anhydride. See under Boron.

Borides. See under the various metals.

Borenol, new (Aschan), A., i, 428.

Borenol, direct transformation of, into campholic and isocampholic acids (Guercert), A., i, 661.

Bornyl borate, preparation of (Vereinigte Chininfabriken Zimmer & Co.), A., i, 351.

ethoxyacetate (FABENFABRIKEN Vorm. F. BAYER & Co.), A., i, 429.

palmitate (v. Sorbe), A., i, 555.

isoBornyl acetate, preparation of (Chemische Fabrik von Heyden), A., i, 351.

esters of fatty acids, preparation of (Chemische Fabrik von Heyden), A., i, 351, 809.

oxalate, preparation of (Basler & Co.), A., i, 429.

Boron, so-called crystalline (Biltz), A., ii, 762.

the ultimate rays of (de Gramont), A., ii, 645.

Boron nitride, preparation of (Stock and Holle), A., ii, 687.

triroxide (boric anhydride), action of aluminium powder on (Wesnon and Ellis), A., ii, 385.

Boric acid, origin of the, in the soffioni of Tuscauy (Nasini), A., ii, 862; (D'Achilardi), A., ii, 955.

in the fumaroles of Vesuvius (Lacroix), A., ii, 766.

detection of, in foods (Mannich and Priess), A., ii, 429.

detection of, in foods by means of turmeric paper (Lavalle), A., ii, 596.

Boron:—

Boric acid, detection and estimation of, in foods (v. Genersich), A., ii, 906.

Boron sulphide, synthesis of (Hoffmann), A., ii, 687.

Boron thiocyanate (Cocksedge), T., 2177; P., 270.

Boron minerals, two new, of contact-metamorphic origin (Knopp and Schaller), A., ii, 507.

“Bourgu.” See Panium stagninum.

Boyle-Mariotte law, application of a deduction from the (Rebenstorff), A., ii, 565.

Brain, human, composition of, at different ages (Koch and Mann), A., ii, 307.

of birds and fishes, chemistry of the (Argiles), A., ii, 905.

material in the, which unites with tetanus toxin (Takari), A., ii, 521.

behaviour of the, towards strychnine (Sano), A., ii, 974.

Brass, analysis of (Schürmann and Arnold), A., ii, 898.

Brasses, electrolytic corrosion of, in synthetic sea-water (Lincoln and Bartells), A., ii, 1039.

Brassica Rapa var. rapifera, essential oil of (Kuntze), A., i, 196.

Brazanquinone, 2-hydroxy- (anhydro-a-naphthoquinoneresorcinol) (v. Kostaneccki and Lampe), A., i, 672.

Brazanquinones (v. Kostanecki and Lampe), A., i, 907.

Brazilin and its derivatives (Engels, Perkin, and Robinson), T., 1115; P., 148.

methylation of (Engels, Perkin, and Robinson), T., 1131.

Brazilic acid, constitution of (Perkin and Robinson), T., 502.

Brazilin and hematoxylin and their derivatives (Engels, Perkin, and Robinson), T., 1115; P., 148.

constitution of (Perkin and Robinson), T., 489; P., 54.

Brazilinic acid, synthesis of (Perkin and Robinson), T., 489; P., 54.

Bromal hydrate, use of, in chemical, microchemical, and microscopic investigations (Schaefer), A., ii, 62.

Bromates, Bromic acid, and Bromides. See under Bromine.

Bromination (Cohen and Cross), A., i, 413; (Acree, Johnson, and Nirdlinger), A., i, 413; ii, 29.

by means of diazo benzene perbromides (Bülow and Schmachtenberg), A., i, 743.
Bromine, preparation of, by Kossuth and Mehrs's method, the formation of magnesium oxychloride by electrolysis of the residual solutions from the manufacture of potassium chloride, and its importance for the (Hof), A., ii, 946.
electrolytic conductivity of, in nitrobenzene solution (Brunner), A., ii, 149.
substitution of, by chlorine in the animal body (Böninger), A., ii, 208.
physiological action of (Togami), A., ii, 872.
Hydrobromic acid (hydrogen bromide), liquid, heat of vaporisation of (Elliott and McIntosh), A., ii, 354.
Bromides, behaviour of, in the human and animal organisms (v. Wyss), A., ii, 875.
excretion of, by the kidney (Hale and Fishman), A., ii, 611.
delicate test for, alone or in solution with chlorides (Jameson), P., 144.
Bromic acid, study of the oxidation phenomena produced by (Bau-
Bigny), A., ii, 577.
and iodic acid, estimation of, by means of thiosulphuric acid (Caso-
lar), A., ii, 222.
Bromates, chlorates, iodates, and per-
iodates, estimation of, by means of formaldehyde, silver nitrate, and potassium persulphate (Brunner and Mellet), A., ii, 222.
Bromine, chlorine, and iodine, separation of, by means of hydrogen peroxide in acid solution (Jannasch), A., ii, 730.
See also Halogens.
Bromine absorption of unsaturated com-
ounds, apparatus for the determination of the (Crossley and Renouf),
T., 643.
\( \alpha \)-Bromo-fatty acids, fission of hydrogen cyanide from amides of, and formation of aldehydes or ketones from (Mossler), A., i, 133.
action of zinc or magnesium on mix-
tures of esters of oxalic acid and of (Rassow and Bauer), A., i, 316.
Bromolmino-acids, esters, stereoisomeric (Hilpert), A., i, 829.
Bromo-. See also under the parent Substance.
Bronzes, old, physico-chemical investigation of, from the excavations in Lalajants, on the S. W. shore of Lake Goutsch in the summer of 1906 (Skinder), A., ii, 381.
Bronzes, analysis of (Schürmann and Arnold), A., ii, 898.
"Brostenite," analyses of (Butureanu), A., ii, 955.
Brownian motion and osmotic pressure (Duclaux), A., ii, 760.
influence of the medium on (Henri), A., ii, 760.
Brucine, new method of oxidising (Leuchs), A., i, 563.
iode derivative of (Buraczewski and Koźniewski), A., i, 1007.
Brucinonic acid and its ethyl ester (Leuchs), A., i, 563.
Buddelia foliata, oil from the leaves and flowers of (Schimmel & Co.), A., i, 668.
Buls, absorption. See under Analysis.
Bunsen flame, internal friction and density of the (Becker), A., ii, 153.
luminosity of the (Lacy), A., ii, 1033.
apparatus for producing colorations in a (Scriba), A., ii, 647.
Burette, circulation (Müller), A., ii, 626.
antomatic safety (Müller and Berchem), A., ii, 775.
a shortened (Tschaplowitz), A., ii, 981.
Burettes, gas, a combined stopcock and capillary connecting tube for (Hill), P., 95.
Burette clamp, new (Müller), A., ii, 1069.
Burseracin and its effects (v. Bolton), A., i, 496.
\( \alpha \)-Butadiene-\( \alpha \)-dicarboxylic acid. See Muconic acid.
Butaldehyde, chloro-, palladium com-
ound (Makowka), A., i, 328.
isoButaldol, crystalline polymeride of (Mus
elius), A., i, 761.
Butane, physical properties of (Lebeau),
A., i, 749.
Butane, \( \alpha \beta \)-tribromo- (Lespieau and Pariselle), A., i, 496.
isoButane, physical properties of (Le-
beau), A., i, 749.
boiling point of (Noyes), A., i, 305.
cycloButane derivatives, transformation of, into cyclopropane derivatives (Demjanoff), A., i, 85.
cycloButanecarboxylic acid and its amide, chloride, and urethane (Zelinsky and Gutt), A., i, 14.
hydrogenation of (Kijner), A., i, 532.
Butanedicarboxylic acids. See Adipic acid and isoPropyimalonic acid.
Butane-\( \alpha \gamma \)-tetraCarboxylic acid, 5-
hydroxy- (Simonsen), T., 1781.
cyclo-Butanol and its reactions (Zelinsky and Gutt), A., i, 14.
some transformations of (Demjanoff and Dojarenko), A., i, 156.
Butanone. See Methyl ethyl ketone.
cyclo-Butanone and its nitrosite (Demjanoff), A., i, 329.
cyclo-Butene, constitution of (Zelinsky and Gutt), A., i, 14; (Willstätter and Bürck), A., i, 402.
Butenoic acid. See Crotonic acid.
$\Delta^a$-Butenoic acid, $\alpha\beta$-dibromo-$\gamma$-hydroxy- (Lespieau and Viguié), A., i, 125.
$\Delta^a$-Buten-3-ol, $\beta$-bromo-, and its acetin, and $\alpha\beta$-triiodo- and its acetate (Lespieau and Pariselle), A., i, 496.
$\Delta^a$-Buten-$\gamma$-ol ($\alpha$-methylallyl alcohol) (Wohl and Losanitsch), A., i, 394.
Butinol and its phenylurethane (Lespieau and Pariselle), A., i, 496.
Butenyl alcohols. See $\Delta^a$-Butenols.
Butter, detection of benzoic acid in (Halphen), A., ii, 906; (Robin), A., ii, 1078.
detection of the unsaponifiable ingredients of cacao-butter in (Mathies and Ackermann), A., i, 637.
Butter-fat, estimation of the caprylic (octoic) acid value of (Dons), A., ii, 238.
Butterfly pupae, influence of the amount of carbon dioxide in the inspired air on the changes in weight of (V. Linden), A., ii, 605.
Butyl alcohol. See Trimethylcarbinol.
isoo-Butyl alcohol, isomeric change of, effected by nitrons acid (Henry), A., i, 2.
thermodynamics of mixtures of water and (Bose and Clark), A., ii, 84.
oxidation of, by a contact process (Orloff), A., i, 306.
isoo-Butyl arsenite (Lang, Mackey, and Gortner), T., 1367; P., 150.
cuburocyanide (Guillemand), A., i, 720.
sec.-Butylacetoacetic acid, ethyl ester (Clarke), A., i, 593.
cyclo-Butylamine (Zelinsky and Gutt), A., i, 14.
$\alpha$-Butylaminocetanal and its derivatives (Paal and van Gember), A., i, 511.
$\beta$-Butyl-$\alpha$-camphoramic acid (FreyIon), A., i, 861.
isoo-Butylcarbimide and its metallic salts (Anschütz), A., i, 327.
cyclo-Butylcarbinol and its isomerisation to pentamethylene derivatives (Demjanoff), A., i, 85.
isoo-Butylcarbylamine (Guillemand), A., i, 719.
$\beta$-n-Butylicinnamic acid (Schroeter and Buchholz), A., i, 170.
cyclo-Butylimethylcarbinol, transformations of (Kijner), A., i, 530.
isomeric changes in the transformations of (Kijner), A., i, 864.
Butylene, dibromo- (Lespieau and Pariselle), A., i, 496.
isoo-Butylene $\alpha\beta$-oxide (Riedel), A., i, 956.
sec.-Butylidenequinone, penta- and hexabromo- (Zincke and Goldemann), A., i, 781.
$\alpha$-Butylinaphthalenes, $\alpha$- and $\beta$-, and their piorates (Bargellini and Melacini), A., i, 775.
isoo-Butylinaphthalenes, $\alpha$- and $\beta$-, preparation of (Daizens and Rost), A., i, 411.
p-sec.-Butylphenol, $\psi$-bromides and quinones of (Zincke and Goldemann), A., i, 780.
isoo-Butyliolcarbamic acid, derivatives and salts of (Anschütz), A., i, 327.
isoo-Butyramide, $\alpha$-amino- (Framchon and Friedmann), A., i, 509.
isoo-Butyranilide, inside chloride of (Staudinger), A., i, 654.
$\nu$-Butyric acid, formation of, from glutamic acid (Braschi and Neuberg), A., i, 860.
oxidation of, by hydrogen peroxide (Dakin), A., i, 74.
Butyric acid, $\alpha$-amino-, synthesis of (Zelinsky and Stadnikoff), A., i, 607.
$\beta$-amino-, derivatives of (Kay), A., i, 773.
$\gamma$-amino-, derivatives of (Gabriel and Colman), A., i, 274.
$\alpha$-amino-$\gamma$-hydroxy-, synthesis of, and its dibenzoyl derivative (Sorensen and Andersen), A., i, 650.
$\alpha$-bromo-, ethyl ester, condensation of, with cyclohexanones (Wallach, Churchhill, and Rentschler), A., i, 404.
$\beta$-hydroxy-, detection and estimation of, in urine (Shaffer; Black), A., ii, 992.
$\beta\gamma$-dihydroxy-, lactone of, and its benzoyl derivative (Carre), A., i, 501.
isoo-Butyric acid, $\alpha$-amino-, $N$-benzoyl derivative, and its amide and lactimone (Mohr and Geis), A., i, 339.
$\beta$-amino-$\alpha$-hydroxy-, ethyl ester, and its hydrochloride and urethane (Les Etablissements Pouleanc Frères & Ernest Fourneau), A., i, 938.
1269

C.

Cacao butter, unsaponifiable ingredients of, and their detection in butter (Matthes and Rohdich), A., i, 199, 532; (Matthes and Ackermann), A., i, 637.

Cacao fibre, crude, estimation of (König; Matthes), A., ii, 236.

Cacodylic acid. See under Arsenic.

Cadinine, isomerisation phenomena during the preparation of (Lefeschkin), A., i, 557.

dihydrobromide and dihydrochloride, action of bromine and chlorine on (Deussen and Lewinson), A., i, 354.

Cadmium, electrolytic valve action of (Schulze), A., ii, 560.

Cadmium alloys with aluminium (Gwyer), A., ii, 286.

with calcium (Doński), A., ii, 279.

with nickel (Voss), A., ii, 196.

Cadmium antimonides (Kurnakoff and Konstantinoff), A., ii, 390.

chloride, specific gravity of aqueous solutions of (V. Birou), A., ii, 185.

Cadmium chloride, alkali double salts of (V. Birou and Aphanassieff), A., ii, 249.

ammonium chromates (Gröger), A., ii, 691.

oxide, velocity of reduction of, by carbon monoxide and the existence of a suboxide (Beislee), T., 154.

potassium calcium sulphate (D'Ans), A., ii, 590.

Cadmium ion, univalent, existence in aqueous solutions of a (Denham), T., 383; P., 76.

Cesium rhodium bromide and chloride (Guthier and Hütlinger), A., ii, 200.

iodate and periodate, specific gravity and solubility of (Barker), T., 16.

polyiodides (Foot and Chalker), A., ii, 586.

nitrate, crystallisation of (Jones), T., 1743; P., 196.

indium selenate (Mathers and Schlüderberg), A., ii, 386.

dicalcium sulphate (D'Ans), A., ii, 590.

trithionate and its monohydrate (Mackenzie and Marshall), T., 1738; P., 199.

Caffeine, decomposition of, by extract of ox-liver (Kotake), A., ii, 1055.

physiological action of (Sano), A., ii, 974.

action of, on frogs (Jacob and Golowinski), A., ii, 1061.

compound of, with lithium benzoate (Bergell), A., i, 1004.

alkali metaphosphates, preparation of (Hoffmann La Roche & Cie.), A., i, 825.

Calcium, chemical properties of (Erdmann and van der Smissen), A., ii, 587.

spectrum of the flame of (Hemsalech and de Watteville), A., ii, 336, 745.

metallic, action of, on metallic oxides, sulphides, and halogen salts (Perkin and Pratt), A., ii, 379.

and magnesium, antagonistic action of (Meltzer and Auer), A., ii, 312, 519.

action of phosphorus on the circulation of, in normal and rachitic children (Flamini), A., ii, 406.

metabolism of. See under Metabolism.

function of, in plants (Grape and V. Portheim), A., ii, 884.

Cadmium alloys (Doński), A., ii, 278.
Calcium amalgam, behaviour of, as electrodes in solutions of neutral salts (Byers), A., ii, 926.

Calcium compounds, colloidal and gelatinous (Neuberg and Rewald), A., ii, 486.

Calcium salts, importance of, for the growing organism (Aron and Sebauer), A., ii, 208; (Aron and Frese), A., ii, 405; (Orgler), A., ii, 606, 872.

Calcium boride, preparation of (Stock and Holle), A., ii, 687.

carbide, synthesis of (lecture experiment) (Knecht), A., ii, 270.

action of, on some ketones (Bodroux and Taboury), A., i, 854.

combination of nitrogen with (Polasci), A., ii, 836.

carbides, estimation of phosphorus in (Hinrichsen), A., ii, 131.

carbonate, polymorphism of (Barlow and Pope), T., 1528; P. 193.

solubility of, in aqueous solutions of potassium chloride and potassium sulphate at 25° (Cameron and Robinson), A., ii, 105.

reaction of, with chlorine water (Richardson), T., 280.

chemical precipitation of, from sea water (Philippi), A., ii, 302.

hydrogen carbonate, preparation and composition of (Keiser and Leavitt), A., ii, 1036; (Keiser and McMaster), A., ii, 1037.

chloride are spectrum, the red portion of the (Meisenbach), A., ii, 645.

decomposition tension of fused (Arndt and Willner), A., ii, 457.

potassium chromate, dimorphism of (Rakowsky), A., ii, 674.

fluoride, band spectrum of (Walter), A., ii, 336.

hydride, action of, on metallic oxides, sulphides, and halogen salts (Perkin and Pratt), A., ii, 379.

hypochlorite, preparation of dry (Chemische Fabrik Griesheim-Elektron), A., ii, 280.

hypochlorites, preparation of (Chemische Fabrik Griesheim-Elektron), A., ii, 692.

hydroxide, action of, on lactose (Kilian), A., i, 128, 715.

influence of potassium chloride on the solubility of, and vice versa (Kernot, D'Agostino, and Pellegrino), A., ii, 568.

hydroxylamite (Ebler and Schott), A., ii, 1030.

Calcium nitrate as manure. See Manurial experiments.

nitrite, molecular volumes of (Rày), P., 240.

oxide (lime), fused, specific heat of (Latschenko), A., ii, 758.

crystallisation of, from its nitrate (Brügelmann), A., ii, 842.

solubility of, in water (Moody and Leyson), T., 1767; P., 202.

reaction of, with sulphur (Thatcher), A., ii, 380.

action of, in excess on copper sulphate solutions (Bell and Taber), A., ii, 107.

as manure. See Manurial experiments.

phosphate, action of ammonium citrate on (Barille), A., ii, 496.

precipitated, manurial trials with (Söderbaum), A., ii, 423.

modification of Petermann's method for estimating citrate-soluble phosphoric acid in precipitated (Fingerling and Grombach), A., ii, 131.

phosphates—the system, CaO—P₂O₅—H₂O (Bassett), A., ii, 675.

Tricalcium phosphate, natural factors in the dissolution of, in soil (Perotti), A., ii, 527.

Calcium silicate and manganese silicate, isomorphism of (Ginsberg), A., ii, 842.

silicide, Ca₃Si₂(Hackspill), A., ii, 559.

preparation of (Goldschmidt), A., ii, 1037.

sulphate, relation of changes of solubility of, and its rate of hydration (Rohland), A., ii, 842.

compound of, with arsenic sulphate (Kühl), A., ii, 36.

See also Gypsum.

sulphates, neutral triple (D'Ans), A., ii, 590.

ammonium sulphate, double. See Ammonium syngenite.

Dicalcium cesium sulphate (D'Ans), A., ii, 590.

Calcium rubidium sulphates (D'Ans and Zeh), A., ii, 104.

sulphide, changes in the colour of, under the influence of light (Mourelo), A., ii, 140.

Calcium cyanamide, influence of sterilisation on (Kappen), A., ii, 424.

decomposition of (Kappen), A., ii, 414.

action of sulphuric acid on (Jona), A., i, 143.

See also under Manurial experiments and Soils.
INDEX OF SUBJECTS.

Calcium foods in growing animals. See Calcium salts.

Calculi, renal. See Renal calculi.

Caliches, Chilian, composition of certain (Dafert, Halla, and Waschata), A., ii, 603.

Calorimeter and Calorimetric study. See under Thermochmistry.

Calumba root, alkaloids and bitter principles of (Feist), A., i, 100.

Camellia oil, Japanese (Kametaka), A., i, 851.

Cameroocopaloresen, from Cameroon copal (Tschorch and Rackwitz), A., i, 96.

Camphene, synthesis of, from nopinone (Wallach), A., i, 997.

oxylene derivatives of (Milobendski), A., i, 92.

hydrate (Aschan), A., i, 428.

Camphenilone, constitution and derivatives of (Bouveault and Blanc), A., i, 134.

Camphocarboxylic acid and its esters and amides and the N-methylol compound of the amide (Einhorn), A., i, 612.

Camphoformeneamine derivatives (Tingle and Williams), A., i, 125, 126, 127.

Camphoformaminoacarbocxylic acid derivatives (Tingle and Williams), A., i, 127.

Camphoformaminoacarbocxylic acid, N-dialkyl derivatives of (Tingle and Williams), A., i, 125.

β-Campholenolactone, synthesis of (Blanc), A., i, 20, 171.

Campholic acid and isocampholic acid, direct formation of, from borneol (Guerrbet), A., i, 661.

Camphor, synthesis of, from nopinone (Wallach), A., i, 997.

absorption spectrum of (Hartley), T., 961; P., 120.

and turpentine oil, connexion of cholic acid and cholesterol with (Schröter, Weitzenböck, and Witt), A., i, 532; (Schröter and Weitzenböck), A., i, 636, 900.

mercury derivatives (Marsh and Struthers), P., 267.

double salts of, with potassium iodide and mercuric iodide (Marsh and Struthers), P., 266.

physiological action of optical antipodes of, on higher organisms (Bruni), A., ii, 876.

separation of, from fenchone (Semmler), A., i, 37.

Camphor, α-bromo-, action of amyl nitrite on, in presence of sodium ethoxide (Clarke, Lapworth, and Wechsler), T., 40.

imino-, action of formaldehyde on (Forster and Holmes), T., 250; P., 9.

nitro-, influence of impurities on the mutorotation of (Lowry and Magson), T., 107.

action of carboxyl chloride in arresting isomeric change in (Lowry and Magson), T., 119.

isonitroso-, action of diazomethane on the two modifications of (Forster and Holmes), T., 242; P., 8.

interaction of, with p-nitrobenzyl bromide and chloride (Forster and Holmes), T., 248; P., 8.

N-ethyl ether of (Forster and Holmes), T., 251; P., 9.

d-Camphor, sulphur derivatives of, and their rotatory power (Hilditch), T., 1619; P., 195.

Camphoracetal (Arbusoff), A., i, 555.

α-Camphoramic acids (Freylon), A., i, 860.

Camphorcarboxylic acid, kinetics of the elimination of carbon dioxide from (Bredig and Balcom), A., ii, 263.

amino salts, state of, in solution as revealed by the rotatory power (Minguin), A., ii, 137.

Camphor group, synthesis in the (Blanc), A., i, 20, 171.

d-Camphoric acid, normal alkyl esters, preparation of (Riedel), A., i, 352.

dl-Camphoric acid, esters (Riedel), A., i, 809.

Camphoroxalic acid, action of primary and tertiary amines on (Tingle and Williams), A., i, 126.

action of certain secondary amines on (Tingle and Williams), A., i, 125.

Camphorquinone, action of hydrogen peroxide on (Forster and Holmes), T., 252; P., 9.

Camphor and terpene series, investigations in the (Tschohageff), A., i, 93.

Camphylamine, benzenesulphonate (V. Braun), A., i, 677.

Camphylpiperidine and its picrate (V. Braun), A., i, 677.

Canal rays. See under Photochemistry.

Cane sugar. See Sucrose.

Gaoutouche (indiarubber), action of nitrous acid on (Gottlob), A., i, 96.

action of nitrogen trioxide on (Harrison), A., i, 39.

oxydases in (Spence), A., ii, 616.

African oxonides of (Gottlob), A., i, 436.
INDEX OF SUBJECTS.

Caoutchouc, vulcanised, theory of (ERDMANN), A., ii, 853.
See also Rubber.

Capillarity, theory of (WHITTAKER), A., ii, 817.

Capillary investigations, new (GOPPELSROEDER), A., ii, 529.
properties of aqueous solutions of fatty acids (v. SZYSZKOWSKI), A., ii, 1018.
polarimeter tube for small amounts of substances (FISCHER), A., i, 545.
use of liquids, time-law of the, and the relationship of velocity to the chemical constitution (OSTWALD and GOPPELSROEDER), A., ii, 263.
tubes, new method for calibrating (v. SZYSZKOWSKI), A., i, 827.

Capparis spinosa, rutin from (WUNDERLICH), A., i, 559.

Caprylic acid. See Octoic acid.

Carbamic acid, dithio-. See Dithiocarbamic acid.

Carbamide and ammonium cyanate, isomerism of (PATTERSON and MC-MILLAN), T., 1050; P., 135.
condensation of β-diketones with (DE HAAN), A., i, 577.
action of secondary as-hydrazines on (MILRATH), A., i, 1014.
action of as-phenylbenzylhydrazone on (MILRATH), A., i, 581.
hydrogen peroxide (TANATAR), A., i, 400.
methylol compounds of (EINHORN and HAMMBERGER), A., i, 141.
organic salts of (BAUM), A., i, 252.

Carbamide, hydroxy- (CONDUCHE), A., i, 12.
N-hydroxy-, constitution of, and its condensation with aldehydes (CONDUCHE), A., i, 12, 154.
thio-. See Thiocarbamide.
See also Urea.

Carbamides, hydroxy-, and carbamidoximes (CONDUCHE), A., i, 12, 154.
thio-. See Thiocarbamides.

Carbamidoacetic acid. See Hydantoic acid.

Carbamido-acids and their salts (LIPPICH), A., i, 861.

Carbamidobis-4:5:6-trimethyl-2-pyrimidone (DE HAAN), A., i, 578.

Carbamidodiacetonitrile and its isomeride (v. MEYER and LEHMAN), A., i, 910.

Carbamidoguanazide and its hydrobromide (FELLIZZARI and REPETTO), A., i, 65.

Carbamido-6-hydroxy-4:5-dimethyl-, -4- and -5-methyl-, -4-methyl-5-ethyl-, and -4-phenyl-pyrimidines (POHL), A., i, 577.

2-Carbamido-2-pyridone-5-carboxylic acid, 3-bromo-, and its methyl ester (BÜLOW and FILCHNER), A., i, 1017.

Carbamidoximes and hydroxy carbamides (CONDUCHE), A., i, 12, 154.
molecular refractions of some (CONDUCHE), A., i, 156.

Carbaminemethylglycollarylamides (FARRICHS and WILDT), A., i, 414.

Carbaminoacetic acid, dithio-, derivatives of (KÖRNER), A., i, 509.

1-Carbamyl-3-ethyl-, -methyl-, and -propyl-pyrazolines (MAIRE), A., i, 290.

Carbamylpyrazole and its dioxime and semicarbazone, and its isomeride (BLAISE and MAIRE), A., i, 391.

Carbanilide. See s-Diphenylcarbamide.

Carbazole, new synthesis of, and the numbering of the positions in (BORSCHT, WITTE, and BOTHE), A., i, 365.
action of finely divided metals on (PADOA and CHIAVES), A., i, 104.

Carbazoline, formation of (CARRASCO), A., i, 913.

Carbethoxy carbimide and its reactions (DIELS and JACOBY), A., i, 613.

Carbethoxydicyglycylglicine, ethyl esters, isomerism of (LEUCHS and LA FORGE), A., i, 723.

Carbethoxydicyglycimide (BERGELL and FEIGL), A., i, 140.

3-Carbethoxy-1:1-dimethylcyclopentan-2-one-3-acetic acid (BLANC), A., i, 171.

Carbethoxyglycyl-N-phenylglycine (LEUCHS and LA FORGE), A., i, 724.

Carbethoxyglycyl-N-phenylglycylglycine, ethyl ester (LEUCHS and LA FORGE), A., i, 724.

Carbethoxyglycyl-N-phenylglycylglycine, N-phenylglycine and its ethyl ester (LEUCHS and LA FORGE), A., i, 724.

Carbethoxyglycylarosine, ethyl ester (LEUCHS and LA FORGE), A., i, 724.

α-Carbethoxy-N-phenylglycylglycine and its esters (LEUCHS and LA FORGE), A., i, 723.

Carbethoxythiocarboximide and the action of diphenylamine on (DIXON and TAYLOR), T., 697; P., 74.

Carbide, apparatus for the estimation of, in iron and steel (MARS), A., ii, 429.

Carbides, formation of some (FRING), T., 2101; P., 240.
See also under the separate Metals.

Carbimides (isocyanates), new method of forming (ÄNSCHÜTZ), A., i, 326.
Carbodiphenylimide, formation of, from phenylcarbimide (Stolle), A., i, 415.

Carbohydrates, colorimetric method of determining the molecular size of (Wacker), A., ii, 135.

Carbohydrates, influence of, on protein metabolism (Marlin), A., ii, 306.

Carbohydrates, parenteral utilisation of (Mendel), A., ii, 306.

Carbon, digestion and absorption of (London and Polowzowa), A., ii, 870.

Carbon, monoxide, commercial, and disinfecting powders (Blyth), A., ii, 328.

Carbon, atomic weight of (Leduc), A., ii, 271.

Carbon alloys with iron (Charpy), A., ii, 697; (Upton), A., ii, 1042.

Carbon tetrachloride, successive substitution of the atoms of chlorine in, by aromatic groups (Boeseken), A., i, 189.

Carbon oxides, chemical action of radium emanation on (Cameron and Ramsay), T., 981; P., 132.

Carbonic acid, preparation of (Rupp), A., ii, 943.

Carbon dioxide, decomposition of, by the silent electric discharge (Holt), P., 271.

Carbon dioxide, equilibria between, at body temperature (Henderson and Black), A., ii, 467.

Carbonic acid, equilibrium between, at body temperature (Henderson and Black), A., ii, 467.

Carbon oxides, chemical action of radium emanation on (Cameron and Ramsay), T., 981; P., 132.

suboxide (Diels and Lalin), A., i, 939; (Diels and Blumberg), A., ii, 103.

Carbon, parenteral digestion and behaviour of (Fehling's solution), A., i, 5; (Kilian), A., i, 128.

Carbon, fugitive, of Colococcus and Phytelephas (Ivanoff), A., ii, 1064.

Carbon, of yeast (Meigen and Spreng), A., ii, 315.

Carbon, colour of phenylcarbimide (Fleig), A., ii, 306.

Carbon, reducibility of, apparatus for experiments at high temperatures and pressures on (Threlfall), T., 1333; P., 131.

Carbon, reducibility of, direct union of, with hydrogen (Bone and Coward), T., 1975; P., 222.

Carbon, interaction of aluminium powder and (Weston and Ellis), A., ii, 849.

Carbon, amorphous, bacteria as agents in the oxidation of (Potter), A., ii, 524.

Carbon, vegetable, absorptive power for air of certain varieties of (Piutti and Magli), A., ii, 585.

Carbon alcohols with iron (Charpy), A., ii, 697; (Upton), A., ii, 1042.

Carbon, specific heat of (Oberhofer and Meuthen), A., ii, 386.

Carbon, influence of phosphorus on (West), A., ii, 237.

Carbon, with iron and phosphorus (Goerens and Dobbstein), A., ii, 1042.

Carbon, with iron and silicon (Gontermann), A., ii, 851.

Carbon, with manganese (Stadelier), A., ii, 592.

Carbon, carbon, of yeasts (Meigen and Spreng), A., ii, 315.

Carbon, colour, of phenylcarbimide (Fleig), A., ii, 306.

Carbon, reducibility of, apparatus for experiments at high temperatures and pressures on (Threlfall), T., 1333; P., 131.

Carbon, reducibility of, direct union of, with hydrogen (Bone and Coward), T., 1975; P., 222.

Carbon, interaction of aluminium powder and (Weston and Ellis), A., ii, 849.

Carbon, amorphous, bacteria as agents in the oxidation of (Potter), A., ii, 524.

Carbon, vegetable, absorptive power for air of certain varieties of (Piutti and Magli), A., ii, 585.

Carbon, carbon, of yeasts (Meigen and Spreng), A., ii, 315.

Carbon, colour, of phenylcarbimide (Fleig), A., ii, 306.

Carbon, reducibility of, apparatus for experiments at high temperatures and pressures on (Threlfall), T., 1333; P., 131.

Carbon, reducibility of, direct union of, with hydrogen (Bone and Coward), T., 1975; P., 222.

Carbon, interaction of aluminium powder and (Weston and Ellis), A., ii, 849.

Carbon, amorphous, bacteria as agents in the oxidation of (Potter), A., ii, 524.

Carbon, vegetable, absorptive power for air of certain varieties of (Piutti and Magli), A., ii, 585.
Carbon dioxide, liberation of, by dead parts of plants (NABORICH), A., ii, 616.
photosynthesis of, by chlorophyll (Ewart), A., ii, 217; (Mameliand Pollacci), A., ii, 881.
estimation of (Jannasch), A., ii, 430.
apparatus for the estimation of (Pozzi-Escot), A., ii, 1071.
soda-lime apparatus for the estimation of (Dennstedt), A., ii, 225.
the antolyser for the automatic estimation of (Keane and Burrows), A., ii, 735.
and other acids, volumetric estimation of, in air (Henriet and Bonyssy), A., ii, 734.
estimation of, in electrolytic chloride (Philosophoff), A., ii, 376.
and oxygen, estimation of small quantities of, in small volumes of saline solutions (Brodie and Cullis), A., ii, 319.
rapid estimation of, in mineral waters (Stränsky), A., ii, 225.
disulphide, low ignition temperature of (Scriba), A., ii, 376.
synthesis of a polymeride of (Losantisch), A., ii, 32.
effect of, on plants and soils (Egorow), A., ii, 421.
estimation of, in benzene (Bay), A., ii, 226.
estimation of, in carborundum (Parr), A., ii, 628.
estimation of, in ferro-alloys, steel, and plumbago by means of an electric furnace (Johnson), A., ii, 630.
estimation of, in iron (De Koninck and v. Winianer), A., ii, 320.
apparatus for the estimation of, in iron (Widemann), A., ii, 934; (Grzeschik), A., ii, 1071.
estimation of, in pig-iron and steel (Orthey), A., ii, 131.
and hydrogen, the Carrasco-Plancher method of estimating, in organic substances (Lenz), A., ii, 65.
See also Charcoal, Diamond, and Graphite.
Carbon acids, fate of, in the dog (Friedmann), A., ii, 205.
Carbon molecule, constitution of the (Thomlinson), A., ii, 763.

Carbon molecule, constitution of the, from the standpoint of thermochemistry (Redgrove), A., ii, 177.
Carbonates, action of, on tetrathionates (Gutmann), A., ii, 173.
See also Percarbonates.
Carbonyl chloride, dissociation of (Bodenstein and Dunant), A., ii, 178.
action of, as an agent for arresting isomeric change (Lowry and Manson), T., 119.
Carbonyl compounds, reaction of, with hydroxylamine and its hydrochloride (Ackee), A., ii, 169.
Carbonyl-2-aminophenol-4-sulphonic acid, 5-nitro- (Farbwerke vorm. Meister, Lucas, & Brüning), A., i, 157.
Carbonylecyanochrysoidine. See Keto-2-phenylbenzotriazin, m-cyano-amino-
imino. See 2-Phenylbenzotriazin, imino- m-cyanoaminos.
Carbonylidimimidiacetic acid, methyl ester, amide and nitrile of (Jongkees), A., i, 960.
Carbonylidobenzene, formation of (Barger), T., 566.
3-4-Carbonylidobenzonitrile acid and its methyl, phenyl, and methoxyphenyl esters, chloride, and anilide (Barger), T., 568.
Carbonylidomethylthiophenapthen, dichloro- (Barger and Ewins), T., 2090.
a-3:4-Carbonylidobenzylthiolethane, a-\textsuperscript{8}-dichloro- (Barger), T., 2084; P., 237.
a-3:4-Carbonylidobenzylthiopropane, a-\textsuperscript{8}-dichloro- (Barger), T., 2085; P., 237.
Carbonylidothyophenapthen, 4:5(or 5:6)-, 1:2-dichloro- (Barger and Ewins), T., 2087.
Carborundum, technical assay of amorphous (Chesneau), A., ii, 328.
estimation of carbon in (Parr), A., ii, 628.
See also Silicon carbide.
a-3-Carboxyl-

Carbostyril-4-carboxylic acid and its ethyl ester (Dieckmann and Meiser), A., i, 895.
Carboxonium dyes (Kehrmann and Dengler), A., i, 1002.
Carboxy-a-acetylglitutaric acid, ethyl ester, synthesis and hydrolysis of (Simonsen), T., 1786.
3-carboxy-a-acetylglitutaric acid and its oxime and semicarbazone (Meldrum and Perkin), T., 1427.
a-3-carboxyaminod-4-piperidylacetic acid and its hydrochloride (Wohl and Losanitsch), A., i, 48.
β-2-Carboxyanilinioethy ethyl ketone (Blaise and Maire), A., i, 566.

4-Carboxybenzeneazo-3-methyl-5-pyrazolone (Bülow and Schaub), A., i, 706.

Carboxybenzeneazosalicylic acids, o- and m- (Grandmougin and Guisan), A., i, 927.

Carboxybenzoyl-α-benzoic acid, o- and p-chloro- (Heller and Schülke), A., i, 995.

α-Carboxy-β-benzoylpropionic acid (Bougault), A., i, 422.

2-Carboxy-4:5-dimethoxyphenylacetic acid, preparation of (Perkin and Robinson), T., 516.

Carboxyethyl. See Carbethoxy.

Carboxyhamoglobin, sensitive reaction for (De Dominicis), A., ii, 643.

α-Carboxy-γ-hydroxy-γ-phenylbutyric acid, lactone of (Bougault), A., i, 422.

Carboxy group, a case of the inhibiting action of (Nierenstein and Webster), A., i, 89.

replacement of the sulphonic group by the in azo-compounds (Lange), A., i, 300.

Carboxylic acids, conversion of, into their aldehydes (Merling), A., i, 653; (Staudinger), A., i, 654.

degradation of, in the animal body (Friedmann), A., i, 421; ii, 719; (Dakin), A., ii, 719; (Knopp), A., ii, 720.

aromatic, new synthesis of, from the hydrocarbons (Schorigin), A., i, 886.

primary and secondary, liberation of carbon monoxide from (Bistrzycki and v. Siemiradzki), A., i, 555.

N-Carboxylic acids, stability of (Leuchs and La Forge), A., i, 723.

Carboxymethämoglobin, influence of light on the formation of (Göber), A., i, 486.

2-Carboxy-5-methoxyphenoxyacetic acid (Engels, Perkin, and Robinson), T., 1146.

synthesis of (Perkin and Robinson), T., 504.

α-Carboxymethyl-α-β-diphenylthiocarbamide, preparation of (Dixon and Taylor), T., 697; P., 74.

Carboxymethylaminodiacetate acid and its derivatives (Jongkees), A., i, 960.

N-Carboxymethyl-leucine, phenylalanine, and 2-phenylglycine and their anhydrides (Leuchs and Geiger), A., i, 541.

3-Carboxymethylrhodonic acid. See Rhodaninaeic acid.

Carboxymethyl-o-thiobenzoic acid (Kalle & Co.), A., i, 451.

Carboxy methylthiocarbamid and the action of diphenylamine on (Dixon and Taylor), T., 696; P., 74.

8-Carboxymethylthionaphthoic acid, preparation of (Farbwerke Vorm. Meister, Lucius, & Brüning), A., i, 797.

1-Carboxyphenyl-5-arsinic acid, 2-amino-, N-acetyl derivative of, and 2-hydroxy- (O. and R. Adler), A., i, 492.

Carboxyphenylazoacetoacetic acid, ethyl ester, and its benzoylhydrazone (Bülow and Schaub), A., i, 706.

Carboxyphenyldiacetonitriles, m- and p- (V. Meyer and Schumacher), A., i, 910.

α-Carboxyphenylthioacetic acid (α-carboxyphenylthioglycolic acid), preparation of (Kalle & Co.), A., i, 605, 984.

1'-5-Carboxy-2-pyridon-2'-5'-dimethylpyrrol-3':4'-dicarboxylic acid, 3-bromo-, 5-methyl 3':4'diethyl ester (Bülow and Filchner), A., i, 1017.

Carbarylamines (isocyanides) and nitriles, character and reactions of (Gullermard), A., i, 718.

Cardamine amara, essential oil of (Kuntze), A., i, 196.

Carnaubic acid, isolation of, from ox kidney (Dunham), A., ii, 407.

Carnine and inosic acid (Hauser and Wenzl), A., i, 561.

Carnitine, constitution of (Krimberg), A., i, 41.

relation of, to oblitine (Krimberg), A., i, 842.

Carnivora, value of amides in (Völitz and Yakwua), A., ii, 207.

Carrotene from carrots and the substances which accompany it (V. Euler and Nordenson), A., ii, 724; (Marchlewski), A., ii, 886.

Carvacromethone from β-hexahydrocarvacrol (Brunel), A., i, 91.

p-Carvacraldehyde and its derivatives, synthesis of (Gattermann), A., i, 29.

Carvacryloside, synthesis of (Ryan and Ebrill), A., i, 716.

Carvenene (A^12-methadiene) (Harries and Majima), A., i, 734.

Carvenone, action of magnesium methyl iodide on (Rupe and Emmerich), A., i, 556.

hydroxylaminooxime and nitrosooxime (Harries and Majima), A., i, 734.

two oximes and imine of (Harries and Majima), A., i, 733.
INDEX OF SUBJECTS.

Carvenylamine (2-amino-Δ4-menthene) and its derivatives (Harries and Majma), A., i, 734.

Carvestrene dihydrobromide and dihydrochloride, formation of (Fisher and Perkin), T., 1888.

dihydrohaloids (Kondakoff), A., i, 195.

Carvestrene (Δ6680-m-menthadiene), synthesis of (Fisher and Perkin), T., 1876; P., 228.

Carvone, action of light on (Ciamician and Silber), A., i, 556.

action of magnesium methyl halides on (Rupe and Emmerich), A., i, 433.

d-Carvenylamine and its p-nitrophenylhydrzone (Borsche, Witte, and Bothe), A., i, 367.

α-Caryophylleine and its nitroso-bromide and its ethoxy compound (Deussen and Lewinsohn), A., i, 354.

Casein, determination of the molecular weight of, and estimation of (Matthaiopoulos), A., ii, 783.

products of hydrolysis of (Skraup), A., i, 930.

influence of temperature on the solubility of, in alkaline solutions (Robertson), A., i, 930.

behaviour of, in acid solutions (L. L. and D. D. Van Slyke), A., i, 375; (Robertson), A., ii, 89.

leucine from (Heckel), A., i, 231.

Casein ions, measurement of the molecular mass of (Sutherland), A., i, 930.

Caseinogen, polypeptidophosphoric acid from (Reh), A., i, 69.

Caseinogens, elementary composition of different (Tangl and Csökas), A., i, 302.

Caseinogenates of ammonium and sodium, dissociation of solutions of the basic (Robertson), A., i, 1027.

Cassiopeium (V. Welsbach), A., ii, 591; (Urbain), A., ii, 849.

Cast-iron. See Under Iron.

Castration, effect of, on metabolism (McCrudden), A., ii, 405.

Catalase, sensitisation of, by fluorescent substances (Zeller and Jodlbauer), A., i, 239.

in embryonic tissues (Mendel and Leavenworth), A., ii, 207.

Catalases of bacteria (Jorns), A., ii, 880.

estimation of, in blood (Löb and Mulzer), A., ii, 958; (Löb), A., ii, 999.

Catalysis and Catalytic pulsations and reactions. See under Affinity, chemical.

Catechin, iodo-, tetramethyl ether, and its acetate (v. Kostanecki and Lampe), A., i, 86.

Catechol (1,2-dihydroxybenzene, pyrocatechol), hydrogenation of (Sataier and Maille), A., i, 529.

reaction of diazonium salts with (Orton and Everatt), T., 1021; P., 118.

action of fused potassium hydroxide on (Blanesma), A., i, 262.

derivatives, methylene ethers, action of phosphorus pentachloride on (Barger), T., 2081; P., 237.

action of thionyl chloride and of phosphorus pentachloride on (Barger), T., 563; P., 50.

action of thionyl chloride on (Barger and Ewins), T., 733; P., 60.

dimethyl ether. See Veratrole.

ethylene ether (Gattermann), A., i, 34.

2-methyl ether. See Guaiaicol.

Catechualdehyde ethylene ether and its azine, synthesis of (Gattermann), A., i, 34.

Cathode. See Under Electrochemistry.

Cathode luminescence spectra. See Under Photochemistry.

Cathode rays. See Under Photochemistry.

Cat's saliva. See Under Saliva.

Caulophyllum thalictroides, fruit of (Stockton and Eldredge), A., ii, 978.

Celadonite from the Feröes (Currie), A., ii, 704.

Celandine oil (Haensel), A., i, 665.

Celastrus scandens, fruit of (Wells and Reeder), A., ii, 58.

Celeste, barytes, and anglesite, artificial production of, and isomorphous mixtures of these substances (Gaubert), A., ii, 38.

Cell and its medium (Peters), A., ii, 209.

equilibrium between the, and its environment, with special reference to red blood corpuscles (Moore and Roaf), A., ii, 204.

theory of chemical energy in the (Loew), A., ii, 710.

oxidation processes in the (Bach and Chodat), A., i, 490.

galvanic. See Under Electrochemistry.

protozoan, and its medium, inorganic salts of the (Peters), A., ii, 209.

Cellulose and its derivatives (Grandmougin), A., i, 250; (Schwalbe), A., i, 321.
INDEX OF SUBJECTS.

Cellulose, dry distillation of (Klason, v. Heidenstam, and Norlin), A., i, 717.

chemistry of the bleaching of (Schwalbe), A., i, 138.

action of ammonium persulphate solutions on (Ditz), A., i, 954.

gradual nitration of (Berl and Klaye), A., i, 504.

action of anhydrous nitric and sulphuric acids on (Rassow and V. Bonge), A., i, 994.

action of nitric acid on (Haeussermann), A., i, 768.

influence of sulphuric acid in the nitration of (Kullgren), A., i, 768.

behaviour of, with sodium hydroxide (Miller), A., i, 78; (Vieweg), A., i, 857.

preparation of alcohol from substances containing (Koerner), A., i, 955.

sulphonic esters of (Aktien-Gesellschaft für Anilin-Fabrikation), A., i, 955.

acetonitrates and nitrates (Berl and Smith), A., i, 505.

formates, preparation of (Bemberg), A., i, 521.

nitrate, deuterification of, by means of acid mixtures (Berl and Klaye), A., i, 504.

hydrocellulose, and oxycellulose, highly nitrated (Berl and Klaye), A., i, 504.

lignin, and cutin, separation of (König; Matthes), A., ii, 236.

Cellulose, nitro-, of American manufacture, decomposition curves of (Willcox), A., i, 606.

Cellulose materials, estimation of water of hydration in (Schwalbe), A., ii, 627.

Cement, micrography of (Stern), A., ii, 589.

See also Mortar.

Centrifugal analysis. See Analysis.

Century, new glucoside from the common (Hérissé and Bourdier), A., i, 903.

Cereals, relation between the effects of liming and of nutrient solutions containing different amounts of acid on the growth of (Hartwell and Pember), A., ii, 420.

influence of different manurial conditions on the assimilation of nutrients by, and the structure of plants (Wagner), A., ii, 1066.

loss of phosphoric acid in the incineration of (Leavitt and Le Clerc), A., ii, 428, 531.

Cereals, polarimetric estimation of starch in (Ewers), A., ii, 543.

Cerebro-spinal fluid (Landau and Halfern), A., ii, 406.

Cerium, arc spectrum of (Bakowski), A., ii, 243.

didymium, and lanthanum, quantitative spectra and separation of (Pollok and Leonard), A., ii, 645.

Cerium salts, abnormal behaviour of, on hydrolysis (Denham), A., ii, 380.

Cerium ammonium molybdate (Barbier), A., ii, 595.

selenates (Cingolani), A., ii, 385.

sulphides and their limits of existence (Biltz), A., ii, 1037.

Cerium, estimation of, in presence of other rare earths (Brown and Palm), A., ii, 736.

Cerium metals, nitrates of, double, with alkali nitrates (Wyrouboff), A., ii, 385.

See also Earths, rare.

Chabazite from Montresta, Sardinia (Pelcanti), A., ii, 864.

Chalcedony, quartz, and opal, relation between (Leitmeier), A., ii, 954.

Chalkone, 2':4'-dihydroxy-. See Phenyl styryl ketone, op-dihydroxy-.

Change of properties in chemistry, discussion of the gradual (Kuriloff), A., ii, 477.

Charcoal, absorption of radioactive emanations by (Boyle), A., ii, 1005.

decolorising action of (Rosenthaler), A., ii, 158; (Glassner and Suida), A., ii, 669.

use of, in vapour density determinations (Dewar and Jones), A., ii, 258.

See also Carbon.

Chavibetol, synthesis of (Béhal and Tiffeneau), A., i, 260.

Cheiroline, an alkaloid containing sulphur, and Cheirole (Wagner), A., ii, 202.

Chemical change. See under Affinity, chemical.

compounds, definite, hardness of solid solutions of (Kurnakoff and Schenckstichschny), A., ii, 832.

constitution, and absorption spectra, relation between (Baly and Desch), T., 1747; P., 173; (Baly and Schaeffer), T., 1808; P., 207; (Baly and Tuck), T., 1902; P., 223; (Baly and Marden), T., 2108; P., 255; discussion, P., 286; (Baly, Collie, and Watson), P., 288.
Chemical constitution and colour (Moore and Gale), A., ii, 368; (Willstätter and Piccard), A., i, 475; (Keirnmann), A., i, 699, 993.

relation of, to colour and fluorescence (Silberrad and Roy), P., 204.

and colour of azomethine compounds (Pope), T., 532; P., 24; (Pope and Fleming), T., 1914; P., 228.

crystalline form, hardness, and density, relation between (Pöschi), A., ii, 673.

and crystalline form of picryl derivatives (Jerusalem and Pope), A., ii, 674.

and dielectric constant, relation between (Stewart), T., 1059; P., 124.

and fluorescence (Kauffmann), A., ii, 5.

fluorescence, and luminescence (Hantsch), A., ii, 446.

and physiological action, relation between, in certain substituted aminoalkyl esters (Pyman), T., 1793; P., 208.

and rotatory power of optically active compounds, relation between (Chardin and Sikorsky), A., ii, 470; (Chardin), A., ii, 548, 912.

and viscosity, relation between (Dunstan and Thole), T., 1815; P., 213; (Dunstan and Stubbs), T., 1919; P., 224.

relationship of velocity of the capillary rise of liquids to the (Ostwald and Goppelsroeder), A., ii, 268.

effect of, on the optical activity of nitrogen compounds (Everatt), T., 1225; P., 148.

effect of, on the rotatory power of optically active ammonium compounds (Jones and Hill), T., 285; P., 28.

effect of, on the rotatory power of optically active nitrogen compounds (Everatt and Jones), T., 1789; P., 212.

dissociation and dynamics. See under Affinity, chemical.

problems, application of low temperatures to (Dewar and Jones), A., ii, 258.

processes, new views on (Wald), A., ii, 478.

reaction. See under Affinity, chemical.

Chemistry in space (Paternò), A., ii, 77; (Ciamician), A., ii, 137.

Chemistry, general and physical, development of, in the last forty years (Nernst), A., ii, 1.

inorganic, development of, in the last forty years (Landolt), A., ii, 31.

medical, isolation of traces of mineral substances from saline solutions in (Meillere), A., ii, 62.

mineral. See Mineral chemistry.

organic, development of, in the last forty years (Graebe), A., i, 1.

structural changes in (Tiffeneau), A., i, 305.

Cherry tree, Japanese. See Prunus pseudo-cerasus var. sieboldii.

Chick, assimilation of phosphorus and calcium during the embryonic life of the (Carpiou), A., ii, 963.

Chicken flesh, hydrolysis of (Osborne and Heyl), A., ii, 967.

Children, composition of gastric juice in (Sommershield), A., ii, 403.

healthy and rachitic, mineral metabolism in (Cronheim and Müller), A., ii, 405.

action of phosphorus on the circulating of calcium in (Flamini), A., ii, 406.

Chitin (Offer), A., i, 98.

preparation of pure, from Boletus edulis (Scholl), A., i, 1065.

Chloral and water, freezing and boiling points of mixtures of (van Rossem), A., i, 501.

condensation of, with primary aromatic amines (Wheeler, Dickson, Jordan, and Miller), A., i, 332.

additive compounds of, with amides (Sülberger), A., i, 961.

alcoholate, use of, in chemical, microscopic, and microchemical investigations (Schaer), A., ii, 62.

alcoholates (Kuntze), A., i, 322.

hydrate, use of, in chemical, microchemical, and microscopic investigations (Schaer), A., ii, 62.

Titration of (Garnier), A., ii, 782.

Chloral-anthranilic and -dianthranilic acids and their bromo-derivatives (Wheeler and Dickson), A., i, 333.

Chloric acid, Chlorates, and Chlorides. See under Chlorine.

Chlorination by means of phosphorus pentachloride (Hoering and Baum), A., i, 527; (Schmidt), A., i, 654.

electrolytic, of the salts of organic acids (Inglis and Wootton), T., 1592; P., 174.

Chlorine, atomic weight of (Noyes and Weber), A., ii, 371; (Edgar), A., ii, 577.
Chlorine and hydrogen, relative atomic weights of (Gray and Burt), P., 215.

changes in the properties of (V. Ferentzy), A., ii, 371.

non-existence of a polymeride of (Briner and Durand), A., ii, 940.

specific heat and dissociation of (Pier), A., ii, 352.

water, reaction of, with calcium carbonate (Richardson), T., 230.

slow combination of, with hydrogen, under the influence of heat (Sirk), A., ii, 172.

Chlorine compounds with antimony and sulphur (Taverne), A., ii, 198.

Hydrochloric acid (hydrogen chloride), preparation of normal, with gaseous hydrochloric acid (Reenstorff), A., ii, 221.

chemical action of radium emanation on (Cameron and Ramsay), T., 984; P., 192.

conductivity and viscosity of solutions of (Green), T., 2023; P., 187.

electrolysis of solutions of pure (Doumer), A., ii, 252, 349; (Guilloz), A., ii, 459.

apparatus for the quantitative electrolysis of (Lewis), A., ii, 350.

velocity of transport of the ions H, Cl, OH in the electrolysis of solutions of (Doumer), A., ii, 458.

transport number for dilute (Drucker and Kršnjavi), A., ii, 559.

liquid, heat of vaporisation of (Elliott and McIntosh), A., ii, 354.

temperatures of maximum density of aqueous solutions of, and their expansion on heating (Scher- nay), A., ii, 479.

and sodium chloride, chemical and physiological properties of a solution of (Peters), A., ii, 411.

action of, on manganese dioxide (Holmes and Manuel), A., ii, 765.

detection of free, in the stomach contents (Steensma), A., ii, 318.

Chlorides, electrolysis of (Brochet), A., ii, 491.

Chloric acid and hydrochloric acid, kinetics of the reaction between; a reaction of the eighth order (Luther and MacDougall), A., ii, 361.

Chlorates and perchlorates, behaviour of, during reduction (Venditori), A., ii, 63.

Chlorine:

Chlorates, detection and estimation of chlorites and hypochlorites in (Carlson and Gelhaar), A., ii, 731.

volumetric estimation of (Knecht), A., ii, 627.

bromates, iodates, and periodates, estimation of, by means of form-aldehyde, silver nitrate, and potassium persulphate (Brunner and Meller), A., ii, 222.

Chlorine and iodine, estimation of, in "erythrosine" (Jean), A., ii, 129.

electrolytic, estimation of carbon dioxide in (Philosophoff), A., ii, 132.

bromine, and iodine, separation of, by means of hydrogen peroxide in acid solution (Jannasch), A., ii, 730.

See also Halogens.

Chloroauric acid. See under Gold.

Chlorocodon from Uganda, a new isomeride of vanillin from (Goulding and Pelly), P., 62.

Chloro-comounds, aromatic, magnesium derivatives of (Hesse), A., i, 592.

See also under the parent Substance.

Chloroform and acetone (Dott), A., i, 306.

decomposition of, by alcoholic alkali hydroxides (Mossier), A., i, 750.

rate of elimination of (Paton; Paton and Lindsay), A., ii, 970.

balance (Waller), A., ii, 541.

Chloroform necrosis, the liver in (Wells), A., ii, 974.

Chlorogenic acid and its salts (Gorter), A., i, 186.

aniline and benzidine salts (Gorter), A., i, 341.

α-Chlorohydrin, rate of hydrolysis of, by water and by alkali, and the influence of neutral salts on the reaction velocity (Senter), P., 89.

Chlorohydrins, formation of (Fourneau and Tippenneau), A., i, 163.

Chloroimino-acids, esters, stereoisomeric (Hilpert), A., i, 829.

Chloromanganokalite, a new Vesuvian mineral (Johnston-Lewis and Spencer), A., ii, 395.

Chlorophyll (Willstätter and Pfannenstiel), A., i, 198; (Willstätter and Benz), A., i, 199; (Marchlewski), A., i, 199.

and its derivatives, absorption spectra of (Müllermeister), A., i, 197.

phosphorus an essential constituent of (Stoklasa, Birdlik, and Just), A., i, 279; (Tsvett), A., i, 440.
Chlorophyll, transformations of, under the influence of acids (Hildt, Marchlewski, and Robel), A., i, 668.

action of acids on (Hildt, Marchlewski, and Robel), A., i, 439.
supposed extracellular photosynthesis of carbon dioxide by (Ewart), A., ii, 217; (Mameli and Pollacci), A., ii, 881.
crystalline (Willstätter and Benz), A., i, 199.
so-called crystallisable (metachlorophyllin), nature of the (Tsvett), A., i, 669.
derivatives, so-called, a new system of (Tsvett), A., i, 669.

Chlorophyllan and phæophytin (Tsvett), A., i, 668.

Chlorophyllian photosynthesis, recent researches on (Mameli and Pollacci), A., ii, 881.

Chlorophyllin, acid derivatives of (Tsvett), A., i, 440; (Marchlewski), A., i, 650.

Chlorophyllite from Vizézy (Barbier), A., ii, 705.

Chloroplasmatic acid. See under Platinum.

Cholesterol, a- and b- (Diels and Linn), A., i, 264.

Cholestanol. See Dihydrocholesterol.

Cholestenone and its ozonide (Dorée and Gardner), T., 1328; P., 173.

relationship of to cholesterol (Diels and Linn), A., i, 164; (Willstätter and Mayer), A., i, 636.

Cholesterol (Diels and Linn), A., i, 164, 263; (Windaus), A., i, 264, 728; (Willstätter and Mayer), A., i, 636; (Diels), A., i, 728.
in bile, influence of tolylene-2,4-diamine on the secretion of (Kusumoto), A., ii, 970.
in ox-bile (Salkowski), A., ii, 1955.
in Ceclenterata (Dorée), A., ii, 769.
isolation of, from fats (Salkowski), A., i, 980.

and its ether and its bromides (Mino-vici), A., i, 531.

origin and formation of (Lifschütz), A., i, 263.

physico-chemical researches on (Porges and Neubauer), A., ii, 90.

double linkings in, and its ozonide (Langheld), A., i, 317; (Molinari and Fenaroli), A., i, 882.

and cholic acid, connexion of, with camphor and turpentine oil (Schrötter, Weitzenböck, and Witt), A., i, 582; (Schrötter and Weitzenböck), A., i, 636, 900.

Cholesterol, crystallisation of (Gaubert), A., ii, 475.

action of fused potassium hydroxide and of hydrogen peroxide on (Pickard and Yates), T., 1678; P., 121.

degradation product of (Schrötter, Weitzenböck, and Witt), A., i, 582; (Schrötter and Weitzenböck), A., i, 636, 900.

origin and destiny of, in animals (Dorée and Gardner), A., ii, 514.

excretion of, by the dog (Dorée and Gardner), A., ii, 514.
ozonic of (Dorée and Gardner), T., 1331; P., 173; (Langheld), A., i, 317; (Diels), A., i, 728; (Molinari and Fenaroli), A., i, 882.

new reactions for (Golodetz), A., ii, 328.

colour reaction of, on oxidation (Lifschütz), A., ii, 233.

b-cholesterol (Diels and Linn), A., i, 164.

Cholesterol group (Menozzi; Menozzi and Moreschi), A., i, 265.

contributions to the chemistry of the (Pickard and Yates), T., 1678, 1928; P., 121, 227.

Cholesteryl oleic acid ester, from pathological organs (Panzer), A., ii, 122.
salicylate (Golodetz), A., i, 20.

Cholesteryl chlorides, a- and b- (Diels and Linn), A., i, 264.

Cholic acid, behaviour of, towards ozone (Langheld), A., i, 316.

and cholesterol, connexion of, with camphor and turpentine oil, and their degradation product (Schrötter, Weitzenböck, and Witt), A., i, 532; (Schrötter and Weitzenböck), A., i, 636, 900.
bismuth salt (Wörner), A., i, 393.

Choline, preparation of, from lecithin (Riedel), A., i, 395.

amount of, in the lecithin of heart muscle (MacLean), A., ii, 967.

quantitative recovery of, from lecithin (Moruzzi), A., i, 395; (MacLean), A., i, 396.

occurrence of, in thymus, spleen, and lymph glands (Schwarz and Lederer), A., ii, 968.

the depressor substance in the thyroid (v. Fürth and Schwarz), A., ii, 968.

physiological action of (Modrakowski), A., ii, 974.

Stańek's method for estimating (Stańek), A., ii, 239.

Christianite of Simiouse, composition of (Barbier), A., ii, 956.
Chromammonium compounds. See under Chromium.

Chromate solutions, optical investigation of the condition of (HANTZSCH and CLARK), A., ii, 646.

Chromic acid and Chromates. See under Chromium.

Chromites in meteorites (TASSIN), A., ii, 956.

Chromium, stereochemistry (PFEIFFER), A., i, 79; (PFEIFFER, PRADE, and STERN), A., i, 506; (PFEIFFER, VORSTER, and STERN), A., i, 507; (PFEIFFER, GASSMANN, and PIETSCH), A., i, 508.

Chromium alloys with cobalt (LEW-KONJA), A., ii, 853.

Chromium chlorides, with manganese (HINDRICHs), A., ii, 856.

Chromium chlorides, with nickel (Voss), A., ii, 195.

Chromium salts, isomerism of (PFEIFFER), A., i, 594.

Chromium, preparation of pure, and its hydrates (RICH), P., 215.

Chromium organic compounds (WERNER, JOVANOvITS, ASCHKINASY, and POSSELT), A., i, 936.

Chromic chloride, molecular weight of the green-blue-blue hydrate of, and neutralisation of, by sodium hydroxide, and hydrolysis of, by potassium iodide and iodate (SAND and GRAMMLING), A., ii, 293, 294.

Chromous chloride, preparation of pure, and its hydrates (RICH), P., 215.

Chromium, detection of (POZZI-ESCOR), A., ii, 900.

Chromium, determination of, in presence of each other (KARSLAKE), A., ii, 635.

Chromic acid, decomposition of, by hydrogen peroxide (RIESENFELD and WESCH), A., ii, 951.

Chromite, separation of tungsten from (v. KNORRE), A., ii, 779.
Cinchonine, Cinchoninone
Cinchona
Cincholeuaponic
Cider, Chrysalis
Chrysazindisulphonic
Chrysalidene
Chromotropic
Chromophore,

bases, barks, of, acid (Roy), 808.

preparation (Hesse), A., ii, 241.

and its dimethyl ether (Farbw erke vorm. Meister, Lucius, & Brüning), A., i, 507.
p-nitro-, and its dimethyl ether (Farbw erke vorm. Meister, Lucius, & Brüning), A., i, 428.

Chrysazin, hydroxy-, and its triacetyl derivative, preparation of (Farbw erke vorm. Meister, Lucius, & Brüning), A., i, 507.

Chrysalidinsulphonic acid, dibromo-,

preparation of (Farbenfabriken vorm. F. Bayer & Co.), A., i, 508.

Chrysoidine, cyano-, and its acetyl and benzoyl derivatives (Pierron), A., i, 926.

Chrysophanic acid, constitution of (Hesse), A., i, 438.

Chrysoephoric acid, constitution of (Hesse), A., i, 438.

Chymosin. See Rennin.

Cider, detection of tartaric acid in (Le Roy), A., ii, 237.

Ciders, detection and estimation of benzoic acid in (Reed), A., ii, 74.

Cincholeuaponic acids, racemic, synthesis of, and their derivatives (Wohl and Losantisch), A., i, 47.

Cinchona alkaloids (Rabe and Buchholz), A., i, 100.
in acetic acid. See Quinatoxins.
barks, estimation of total alkaloids in (Cohen), A., ii, 986.
bases, indicators in the titration of (Rupf and Seegers), A., ii, 239.

Cincholeuaponic acids, racemic, synthesis of, and their derivatives (Wohl and Losantisch), A., i, 47.

Cinchona alkaloids (Rabe and Buchholz), A., i, 100.
in acetic acid. See Quinatoxins.
barks, estimation of total alkaloids in (Cohen), A., ii, 986.
bases, indicators in the titration of (Rupf and Seegers), A., ii, 239.

Cincholeuaponic acids, racemic, synthesis of, and their derivatives (Wohl and Losantisch), A., i, 47.

Cinchophoric acid, constitution of (Rabe and Buchholz), A., i, 100.

sulphate, acid persulphate, and picrate (Wolffenstein and Wolff), A., i, 283.

Cincholeuaponic and its methiodide, sodium salts of (Rabe and Schneider), A., i, 361.

and its oxime and their derivatives (Rabe and Buchholz), A., i, 100.

Cinenic acid, preparation of, and condensations with (Rupf and Liechtenhan), A., i, 390.

Cinnamaldehyde hydrogen persulphide (Brunner and Vuilleumier), A., i, 900.

Cinnamylacrylic acid. See Cinnamylideneacetic acid.

γ-Cinnamyl-α-oeroticonic acid and α-hydroxy- (Bougault), A., i, 538.

Cinnamic acid and its derivatives, addition of halogens to (Michael and Smith), A., i, 168.

velocity of esterification of, by means of alcoholic hydrogen chloride (Kailan), A., ii, 27.

conversion of, into styrene by means of moulds (Herzog and Ripke), A., ii, 1064.

and benzoic acid, separation of (De Jong), A., ii, 993.

Cinnamic acid, alkaloidal salts, and their optical activity (Hilditch), T., 703; P., 61.

Cinnamic acid, bornyl and menthyl esters, optical properties of (Hilditch), T., 1.

ethyl ester, action of sodium benzyl cyanide on (Avery and McDole), A., i, 343.

menthyl ester, optical rotatory power of (Hilditch), P., 286.

Cinnamic acid, amino-derivatives and p-nitro-, alkylaminoalkyl esters of (Farbw erke vorm. Meister, Lucius, & Brüning), A., i, 169.

o-, m-, and p-nitro-, velocity of esterification of, by means of alcoholic hydrogen chloride (Kailan), A., ii, 27.

αllo-Cinnamic acid, oxidation of (Rieber), A., i, 639.

Cinnamidic and o-nitro-, action of potassium hypochlorite on (Weerman), A., i, 22.

Cinnamoylsaliclyc anhydride (Farbenfabriken vorm. F. Bayer & Co.), A., i, 984.

Cinnamoyltriphenylmethane, isomeric (Schmidtlin and Hodgson), A., i, 240.

Cinnamylideneacetic acid (cinnamylideneacetic acid) and its methyl ester, action of ammonia and amines on (Riedel), A., i, 536.

Cinnamylideneacetophenone, action of hydroxylamine on (Ciusa and Terni), A., i, 763.

Cinnamylideneacetophenone-hydroxylamines and -oximes and their benzoyl derivatives, α- and β- (Ciusa and Terni), A., i, 763.
INDEX OF SUBJECTS.

1283

p-Cinnamylideneaminodimethylalaniline and its hydrochlorides (MOORE and GALE), A., i, 369.

Cinnamylidenecarbamidoxime (CON- DUCHE), A., i, 154.

Cinnamylidene esters, reactions of, with organic magnesium compounds (REIMER and REYNOLDS), A., i, 988.

Circulation and respiration, effects of excess of carbon dioxide and want of oxygen on (HILL and FLACK), A., ii, 706.

See also Heart.

 estimation of, in lemon grass oil (BLOCH), A., ii, 782.

Citral hydrate, preparation of (COULIN), A., i, 999.

condensation of, with ketones (COULIN), A., i, 1000.

isomeride of (COULIN), A., i, 1000.

Citralides, formation of, from their corresponding acids (MERLING), A., i, 653.

Citralidenemalonic acid, methyl ester (MEERWEIN), A., i, 90.

Citric acid in wine (HUBERT), A., ii, 544.

the natural, of wine (DUPONT), A., ii, 904.

new synthesis of (FERRARIO), A., i, 758.

detection of, in wine, &c. (FAVREL; ASTRUC; DENIGES), A., ii, 640.

Citric acid, ammonium salt, action of, on calcium phosphate (BARILLE), A., ii, 496.

bismuth salt (TELLE), A., i, 852.

calcium salt, hydrates of (VAN ITALLIE), A., i, 854.

glycinium salt (TANATAR and KUROY-

ski), A., i, 758.

basic ferric salt (ROSENTHALER and SIEBECK), A., ii, 246.

Citronella series, compounds of the (HARRIES and HIMMELMANN), A., i, 662.

Citronellaldehyde, ozonides of (HARRIES and HIMMELMANN), A., i, 662.

Citronelllic acid, ozonides of (HARRIES and HIMMELMANN), A., ii, 663.

Citronellol ozonide (HARRIES and HIMMELMANN), A., i, 663.

Cladoniaeae, chemical monograph of the (ZOPP), A., ii, 526.

Claisen reaction, mechanism of the (TINGLE and CORSHNE), A., i, 732.

Clay, separation of, in the estimation of humus (MOORE and HAMPTON), A., ii, 744.

Clay analysis (BLOOR), A., ii, 71.

Coagulation and agglutination (ABRE- NITUS), A., ii, 822.

process of, from colloidal solutions (WOUDSTRA), A., ii, 160; (LOTTER- MOSER), A., ii, 365.

Coagulometer, Buckmaster's, modification of (GOLLA), A., ii, 766.

Coaguloses (LAWBOFF), A., i, 844.

Coal, proximate constituents of (BEDSON), A., ii, 302.

relation between the composition of, and the amounts of carbon monoxide and dioxide contained in gas distilled from it (VIGNON), A., ii, 177.

Parr's method of estimating the heat of combustion of (PARR), A., ii, 533; (CONSTAM), A., ii, 734.

rapid estimation of sulphur in (KOMAR- ROWSKY), A., ii, 892.

Coal gas, estimation of naphthalene in (GAIR), A., ii, 135.

See also Gas, illuminating.

Coal tar, occurrence of nononaphthene in (AHREN and V. MOZDZEŃSKI), A., i, 618.

Cobalt, iron, and nickel, experiments on the passivity of (BYERS), A., ii, 1026.

Cobaltammine salts (WERNER), A., ii, 42; (WERNER, BINDSCHEIDER, and GRÜN), A., ii, 43; (SAND and BÜKMAN), A., ii, 44.

iodo- (WERNER), A., ii, 950.

Cobalt alloys with aluminium (GWIYER), A., ii, 286.

with antimony, bismuth, chromium, lead, tin, thallium, silicon, and zinc (LEWKONJA), A., ii, 853.

with arsenic, freezing point curve of (FRIEDRICH), A., ii, 387.

with copper (SAHMEN), A., ii, 186.

with lead (DUCELLIEZ), A., ii, 594.

with tin (LEWKONJA), A., ii, 853; (SCHEMTSCHUSCHNY and BELYNSKY), A., ii, 855.

Cobalt salts, abnormal behaviour of, on hydrolysis (DENHAM), A., ii, 380.

compounds of, with ethylenediamine and propylenediamine (PEIFER, GASSMANN, and PIRTSCH), A., i, 503.

Cobalt arsenides (DUCELLIEZ), A., ii, 853.

ammonium chromates (GRÖGER), A., ii, 691.

molybdate and nickel molybdate (POZZI-ESCOT), A., ii, 1042.

oxides, dissociation pressures of (FOOTE and SMITH), A., ii, 647.

sulphides (I. and L. BELLUCCI), A., ii, 196.
Cobalt sulphides, freezing point diagram of (FRIEDRICH), A., ii, 500.

Cobaltinitrites, studies on the (CUNNINGHAM and PERKIN), P., 212.

Cocos, cocoa, cocaine, cocoa, cobra, cobaltammine, and pyridine thiocyanates, action of iodine on (PFEIFFER and TILGNER), A., i, 875.

Cobalt ethylenediamine and pyridine thiocyanates, detection of, action of iodine on (PFEIFFER and TILGNER), A., i, 614.

Cobalt dioximines (TSCHUGAEFF), A., i, 615.

Cobaltinitritoaquodimethylglyoximine (TSCHUGAEFF), A., i, 616.

Cobaltinitritodimethylglyoximinic acid and its salts (TSCHUGAEFF), A., i, 616.

Cobalt, detection of, in presence of large quantities of nickel (POZZI-EScot), A., ii, 988.

Cobalt, detection of, in presence of nickel (POZZI-EScot), A., ii, 988.

Cobalt, simultaneous qualitative test for (GROSSMANN and HEILBORN), A., ii, 635.

Cobalt, detection and estimation of (POZZI-EScot), A., ii, 899.

Cobalt, colorimetric estimation of, in presence of each other (CHALLINOR), A., ii, 988.

Cobalt, estimation and separation of (POZZI-EScot), A., ii, 229, 539, 540.

Cobalt, separation of iron from (LABY), A., ii, 988.

Cobaltammine salts and Cobaltinitrites.

See under Cobalt.

Cobra poison. See Poison.

Coca, assay of (GRESHOFF), A., ii, 441, 997; (DE JONG), A., ii, 997.

Java, assay of ecgonine in (DE JONG), A., ii, 239.

Coca leaves, estimation of total alkaloids in (DE JONG), A., ii, 440; (GRESHOFF), A., ii, 441.

Cocaine in Java coca (DE JONG), A., ii, 825.

Cockchafer, natural melanin of the (ISHIZAKA), A., i, 280.

Cocoa, estimation of fat in (KREUTZ), A., ii, 641.

Cocoanut. See Cocos nucifera.

Cocoanut oil, new constant for the detection of (HANUS and STEKL), A., ii, 641.

Cocos nucifera, composition of the milk and ferment of the fruit of (DE KRUyFFE), A., ii, 526.

\( \psi \text{-apo} \)Codeine and apomorphine, relation between (KNORR and RAABE), A., i, 908.

IsoCodeine, relationship of, to codeine (KNORR and HöRLEIN), A., i, 42.

Codeines, four isomeric, relationship of, to the morphines (KNORR and HöRLEIN), A., i, 42.

Cod ide, \( \alpha \) and \( \beta \)-chloro, hydrolytic products of (KNORR and HöRLEIN), A., i, 361.

\( \beta \)-chloro- (KNORR and HöRLEIN), A., i, 42.

Cod liver oil, leucamines of (HAWK), A., ii, 308.

Coelenterata, cholesterol in (DORÉE), A., ii, 769.

Coelostin-blue B (correin RR), compounds of, with amino-compounds, and its picate (GRANDMOUGIN and BODMER), A., i, 290, 572.

Coelostin-blue, compound of, with aniline (GRANDMOUGIN and BODMER), A., i, 290.

Coelococcus, carbohydrates of (IVANOFF), A., ii, 1064.

Co-enzyme of expressed yeast in juice (BUCkNER and KLATTE), A., i, 350.

Coffalic acid (GORTER), A., i, 346.

Coffee (GORTER), A., i, 186, 345.

Coffee extract, Liberian (GORTER), A., i, 186.

Coke, conversion of diamond into, in high vacuum by cathode rays (PARSONS and SWINTON), A., ii, 275.

Colchicine, physiological effects of (DIXON and MALDEN), A., ii, 520.

Collidine and its hydrochloride, absorption spectra of (PURVIS), A., ii, 745.

and its nonachloro-, absorption spectra of (PURVIS and FOSTER), A., ii, 244.

Colloid producer, gelatose as (LIESENGANG), A., ii, 476.

Colloidal granules, influence of the reaction of the medium on the size of (MAYER, SCHEFFER, and TERRONE), A., ii, 24.

Colloidal solutions (Svedberg), A., ii, 25.

does Beer's law hold for? (SCARPA), A., ii, 244.

electrical nature of (DUCALUX), A., ii, 760; (PAPPADÁ), A., ii, 1024.

viscosity of (FAWSITT), T., 1004; P., 121; (WOUDSTRA), A., ii, 464.

stability of (Svedberg), A., ii, 364.
Colloidal solutions in galvanic cells, coagulation of (Biltz), A., ii, 822.
See also Hydrogels and Hydrosols.

Colloidal, amorphous, and crystalline states (v. Weimann), A., ii, 90.

Colloids and their adsorption compounds (Biltz), A., ii, 476.

System of (Ostwald), A., ii, 820.

Modification of Wolfgang Ostwald's system of (v. Weimann), A., ii, 820.

Theory of (Jordis), A., ii, 675, 820, 1023.

Investigation of, by the filtration method (Bechhold), A., ii, 24, 823.

Quantitative investigations on the electrical synthesis of (Svedberg), A., ii, 256.

Changes in the physical state of (PauU and Handovsky), A., i, 707.

Effect of electrolytes on the viscosity of (Gokun), A., ii, 821.

Diffusion of (Herzog and Kasarnowske), A., i, 707.

Influence of temperature on the coaggregation of (Buxton and Rahe), A., i, 707.

Mutual flocculation of (Teague and Buxton), A., ii, 365.

Diastatic function of (Duclaux), A., ii, 25.

Physico-chemical investigations on soaps considered as (Mayer, Schleffer, and Terroine), A., ii, 264.

Influence of, on the absorption of gases, especially of carbon dioxide in water (Findlay and Harby), A., ii, 1024.

Biochemistry of (Feigl and Rollet), A., ii, 312.

Influence of, on enzymes (Pincussohn), A., ii, 308.

Influence of, on haemolysis (Meyer), A., ii, 513.

Inorganic, electrical transport of (Meyer), A., ii, 458.

Influence of, on autolysis (Ascoli and Izar), A., ii, 121, 713.

Precipitated, nature of (Foote), A., ii, 821.

Colour and constitution (Moore and Gale), A., i, 363; (Willsstätter and Piccard), A., i, 475; (Kehrmann), A., i, 699, 993.

Of azomethine compounds (Pope), T., 532; P., 24; (Pope and Fleming), T., 1914; P., 228.

Colour and fluorescence, relation of, to constitution (Silberrad and Roy), P., 204.

Dependence of, on temperature (Kurbatoff), A., ii, 4.

In the triphenylmethane series, cause of (Green), P., 206.

Coloured flames. See Flames.

Liquids, cause of the decoloration of, by means of various charcoals (Glassner and Suida), A., ii, 669.

Sals, theory of (Fecht), A., ii, 916.

Colouring matter, red, C₃H₂O₂S₂, of the thionaphthen series, preparation of a (Kalle & Co.), A., i, 672.

C₃H₃H₂O₂N₃, and its acetyl derivative, from isatin chloride and α-naphthol (Bezdzik and Friedländer), A., i, 674.

C₃H₃H₂O₂NCl, from isatin chloride and 2-chloro-α-naphthol (Bezdzik and Friedländer), A., i, 674.

C₂₃H₂₃O₂N₂, from 2-methylquinoline and methyl salicylate (Spady), A., i, 915.

C₅H₅O₂N₅, and its salts and leuco-base, from o-dimethylaminobenzyl-diethylaminobenzoylbenzene and diethylaniline (Guyot and Pignet), A., i, 570.

Fixation of different derivatives of the same, and explanation of dyeing (Pelet-Jolivet and Andersen), A., ii, 1026.

Colouring matters, action of halogenes on aromatic amines and their use in the synthesis of certain (Ostrogoch and Silbermann), A., i, 373.

Formation of, in ultra-violet light (Schall), A., i, 289.

Study of, in solution (Pelet-Jolivet and Wild), A., ii, 1025.

Classification of solutions of (Freundlich and Neumann), A., ii, 820; (Pelet-Jolivet and Wild), A., ii, 1025.

Absorption of, by various charcoals (Glassner and Suida), A., ii, 669.

Of the stilbene group (Green and Baddiley), T., 1721; P., 201.

Acid, sals of, with guanidine, dicyanodiamide, and melamine (Radberger), A., i, 1001.
INDEX OF SUBJECTS.

Colouring matters, acidic and basic, dissociation by adsorbing substances of the compounds formed by (Pelet-Jolivet), A., ii, 18.

influence of acids and bases on the absorption of, by wool (Pelet-Jolivet and Andersen), A., ii, 89.

basic, iodometric estimation of (Pelet-Jolivet and Garuti), A., ii, 441.
sulphur, as derivatives of thiozone (Erdmann), A., ii, 831.
volumetric estimation of (Pelet-Jolivet and Garuti), A., ii, 441.
estimation of the fundamental, of urine (Browniński and Dabrowski), A., ii, 443.
See also Indicators, Pigments, and Tannins.

Colouring matters, natural vegetable. See also:—
Alizarin.
Anthocyanins.
Brazilin.
Catechin.
Curcumiu.
Dioscin.
Ellaieg acid.
Hæmatoxylin.
Indigo.
Indigotin.
Morindin.
Quercitin.
Rosocyianin.
Rottlerin.
Rutin.

Columbamine and its derivatives from calumba root (Feist), A., i, 100.

Columbium (niobium), atomic weight of, and its salts (Balke and Smith), A., ii, 1043.
spectrum of, and its pentabromide, oxybromide, and iodide (Barr), A., ii, 1045.
are spectrum of (Hildebrand), A., ii, 1045.
electrolytic valve action of, and a classification of the behaviour of electrolytic anodes (Schulze), A., ii, 350.

Columbium sulphide (Biltz and Gonder), A., ii, 114.

Coma, metabolism in a case of, under rectal feeding (Laidlaw and Ryffel), A., ii, 311.

Combustible powders, action of alkali salts of a fixed base on the combustion of (Dautriche), A., ii, 275.

Combustion without flame (Meunier), A., ii, 276, 463.
organic, a new catalyst in, according to the Carrasco-Plancher method (Carrasco and Belloni), A., ii, 631.

Combustion phenomena, simple gas burner contrivance for showing (Thorner), A., ii, 341.

Commiphoric acids, α-, β-, and γ-, and Commiphorinic acid (V. Friedrichs), A., i, 97.

Complex formation, influence of temperature on, in solution (Benrath), A., ii, 567.

Compounds, non-dissociated, spectra of (Bequehel), A., ii, 139.

Compressibility, surface tension, and other properties, relation between (Richards and Mathews), A., ii, 158.
thermal expansion, atomic volume, and atomic heat of metals, relation between (Grüneisen), A., ii, 563.

Condenser, new forms of (Stoltzenberg), A., ii, 938.
new aspirating reflux (Vigreux), A., ii, 938.
new aspirating reflux, and recuperator for rapid evaporation (Vigreux), A., ii, 938.
new reflux, for extraction apparatus (Merkel), A., ii, 478.

Congo-copalic acid, -copaloric acid, and -copaloresens from Congo-copal (Engel), A., i, 559.

Conifers, resins from (Schkateloff), A., i, 816.

Conine, new isomeride of (Guareschi), A., i, 1008; (Issoglio), A., i, 1009.

Co-ordinated compounds, constitution of (Briggs), T., 1564; F., 94.

Copals, Manila and Pontianac (Coffignon), A., i, 436.

West African (Tschirch and Rackwitz), A., i, 96.

West African, solubility of "half-hard" (Coffignon), A., i, 39.

Copper, electrolytic extraction of, from its ores (Juman), A., ii, 282.
electrolytic valve action of (Schulze), A., ii, 560.
electrolysis of solutions of (Meyer), A., ii, 803.
and selenium, freezing point diagram of (Friedrich and Leroux), A., ii, 696.
electrolytic oxidation of (Schmiedt), A., ii, 946.
reaction of, with nitric acid (Stansbie), A., ii, 497.
Copper, interaction of, with nitric acid in presence of metallic nitrates (Rennie, Higgins, and Cooke), T., 1162; P., 141.

action of oxygen on tin, zinc, and, and on its alloys with tin and zinc (Jordis), A., ii, 107.

direct action of radium on (Perman), T., 1775; P., 214.
as oxygen carrier (Cervello), A., i, 1027.

Copper alloys, colorimetric method for the estimation of small percentages of iron in (Gregory), T., 93.

with aluminium (Gwyer), A., ii, 284.
electrolytic corrosion of (Rowland), A., ii, 381.

with calcium (Donski), A., ii, 280.
with cobalt, iron, magnesium, and manganese (Sahmen), A., ii, 186.
with magnesium (Urazoff), A., ii, 186.

with nickel and zinc, constitution of (Tafel), A., ii, 846.

with phosphorus. See Phosphor-copper.

with tin (Sackur and Pick), A., ii, 496; (Giolitti and Tavanti), A., ii, 946.

with zinc, heat treatment of (Bengeough and Hudson), A., ii, 186.

Copper salts, action of radium emanation on solutions of (Curie and Giedttsch), A., ii, 793.

and iron salts in presence of alkalies and acids (Frischer), A., ii, 947.

Cuprammonium salts (Horn), A., i, 121.

See also under Copper organic compounds.

Copper carbonate, basic, solubility of precipitated, in solutions of carbon dioxide (Free), A., ii, 848.

carbonates, conditions of formation of natural (Millosevich), A., ii, 282.
chloride, and barium and sodium chlorides, and water, the system (Schreinemakers and de Baat), A., ii, 1020.
ammonium chromates (Göger), A., ii, 691.

hydroxide, heterogeneous colloidal (Schild), A., ii, 197.

oxides, dissociation pressures of (Foote and Smith), A., ii, 847.

chromium double oxides, dissociation of (L. and P. Wöhler), A., ii, 387.
sulphate, action of lime in excess on solutions of (Bell and Taber), A., ii, 107.
hydrates of (Bell and Taber), A., ii, 382.

Copper ammonium and potassium calcium sulphates (D’Ans), A., ii, 590.

Cuprous ammonia halides (Lloyd), A., ii, 847.
iovide, electrical conductivity of solid (Badeker and Pauli; Badeker), A., ii, 654.
oxide, oxidation by means of, in strongly alkaline solution (Ehrenfeld), A., ii, 848.
ammonio-sulphate (Bouzat), A., ii, 187.

Cupric salts, colour of, in aqueous solution (Sidgwick and Tizard), T., 187.
chloride, flame spectrum of (Kien), A., ii, 1001.

Copper organic compounds:—

Cuprammonium salts (Horn), A., i, 121; (Horn and Graham), A., i, 392.

Copper acetylide. See Acetylene, copper compound.
glycine sulphates, physico-chemical study of the complex (Barker), A., i, 323.

Copper, titration of, by Volhard’s method (Theodor), A., ii, 898; (Kuhn), A., ii, 1072.

and iron, detection of (Delépine), A., ii, 633.

and nickel solutions, colorimetric comparison of (Milbauer), A., ii, 71.
influence of temperature on the electrolytic precipitation of, from nitric acid (Withrow), A., ii, 432.
preservation of metallic, by titanous sulphate (lecture experiment) (Knecht), A., ii, 270.
estimation of, colorimetrically (Milbauer and Stanek), A., ii, 69.
estimation, electrolytically, of minute quantities of (Free), A., ii, 227.
estimation of, volumetrically (Jameson, Levy, and Wells), A., ii, 634.
lead, and silver, estimation of, in complicated organic salts (Rindl and Simonis), A., ii, 432.
estimation of, in pyrites (Remondini), A., ii, 323.

use of ammonium persulphate in the separation of manganese from, in acid solutions (Gottschalk), A., ii, 433.

separation of nickel from (Thiel), A., ii, 539.
electrolytic separation of silver and (Gillett), A., ii, 226.

See also White metal.

Copper mirrors, deposition of, on glass (Neogi), A., ii, 848.
Copper-plating baths, rapid analysis of (PANNAIN), A., ii, 537.

Coprostanone and its oxime, semicarbazone, and phenyllazine compound (DORÉE and GARDNER), T., 1628; P., 196.

Coprosterol (DORÉE and GARDNER), T., 1625; P., 196.

Coprosterol and its acetate and benzoate (DORÉE and GARDNER), T., 1630; P., 196.

Cordierite from Canada (EVANS and BANCROFT), A., ii, 604.

Coriander oil (HAENSEL), A., i, 665.

Coriocrinol from Anthoza (MÖRNER), A., ii, 517.

Corydalis, fruit of (STOCKTON and ELDREDGE), A., ii, 978.

Corybas, action of Röntgen rays on (BORDAS), A., ii, 9.

Corydalis roots, Japanese, protopine of (MAKOSHI), A., i, 908.

Coromandel, tubers, Chinese, the alkaloids of (MAKOSHI), A., i, 825.

Corunnum, action of Röntgen rays on (BORDAS), A., ii, 9.

Cotunnite, Vesuvian, radioactivity of (ROSSI), A., ii, 9.

Coumaralonic acid, bromo-, action of N-amino-compounds on (BÖLOW and FILCHNER), A., i, 1017.

1:2 Coumaran, attempt to synthesise (HELDIG), A., i, 357.

Coumaran group, studies in the (V. KOSTANECKI and LAMPE), A., i, 442.

o-Coumaric acid, ethyl ester, and sodium salt (FRIES and KLOSTERMANN), A., i, 822.

o-Coumaric acids, formation of, from coumarins (FRIES and KLOSTERMANN), A., i, 820.

Coumarin and thio-, and their mercurichlorides (CLAYTON), T., 525; P., 26.

pharmaco-dynamic characters of (ELINGER), A., ii, 1060.

derivatives (REYCHLER), A., i, 441.

Coumarin, 6- and 7-chloro-, formation of (CLAYTON), T., 2021.

d,l-dihydroxy-, and its diacetate (GATTERMANN), A., i, 31.

Coumarins and thio-, residual affinity of, as shown by their additive compounds (CLAYTON), T., 524; P., 26.

formation of (CLAYTON), T., 2016; P., 229.

conversion of, into coumarinic acids and o-coumaric acids (FRIES and KLOSTERMANN), A., i, 820.

reduction of, with zinc dust in alkaline solution (FRIES and FICKEWIRTH), A., i, 822.

Coumarin-3-carboxylic acid, preparation of (HAARMANN & RIEIMER), A., i, 345.

Coumarin-4-carboxylic acid and its esters (DIECKMANN and MEISER), A., i, 894.

Coumarinic acids, formation of, from coumarins (FRIES and KLOSTERMANN), A., i, 820.

Coumarone and hydrocoumarone derivatives from 4:7-dimethylcoumarin (FRIES and FICKEWIRTH), A., i, 824.

chlorohydrin and glycol (BOES), A., i, 444.

Covellite from Servia (STEVANOVIC), A., ii, 396.

synthesis of (CORNT), A., ii, 396.

Cows, protein minimum in the food of, A., ii, 607.

Crab extract (ACKERMANN and KUTSCHER), A., ii, 53.

Crangitine and its hydrochloride and aurichloride from crab extract (ACKERMANN and KUTSCHER), A., ii, 53.

Crangonine and its aurichloride from crab extract (ACKERMANN and KUTSCHER), A., ii, 53.

Crawfish, digestive gland of the (BRADLEY), A., ii, 405.

Creatine and creatinine (MELLANBY), A., ii, 308.

formation and destruction of, in perfused organs (GOTTLIEB and STANGASSINGER), A., ii, 515.

behaviour of, in autolysis (STANGASSINGER; GOTTLIEB and STANGASSINGER), A., ii, 515; (ROTHMANN), A., ii, 967.

in frog's muscle (BROWN and CATHCART), A., ii, 516.

in meat and meat extracts (EMMETT and GRINDLEY), A., ii, 53.

excretion of (VAN HOOGHENHUYTE and VERPOELGH; SHAFFER), A., ii, 971.

in hepatic disease (MELLANBY), A., ii, 54.

Creatinine and creatine (MELLANBY), A., ii, 308.

distillation of (ENGELAND), A., i, 958.

in frog's muscle (BROWN and CATHCART), A., ii, 516.

of infants' urine (FUNARO), A., ii, 716.

in meat and meat extracts (EMMETT and GRINDLEY), A., ii, 53.

excretion of (VAN HOOGHENHUYTE and VERPOELGH; SHAFFER), A., ii, 971.

excretion of, in hepatic disease (MELLANBY), A., ii, 54.

Creatinine metabolism. See Metabolism.

Cresol, poisoning by (BLUMENTHAL and JACOBY), A., ii, 55.

o-Cresol, synthesis of pulenone derivatives from (AUWERS and HESSENLAND), A., i, 550.
o-Cresol, 3-bromo-, 3-bromo-5-nitro-, and its potassium salts, and 5-bromo-3-nitro-, potassium salts of (Robertson), T., 789; P., 73.

m-Cresol, estimation of, in cresol mixtures (Raschig; Herzog), A., ii, 233.

p-Cresol, condensation of, with epichlorohydrin (Boyd and Marle), T., 839; P., 92.

action of potassium persulphate on (Kumagai and Wolffenstein), A., i, 159.

m- and p-Cresol methyl ethers, sulphination of (Smiles and Le Rossignol), T., 756.

Cresols, o-, m-, and p-, bisazo-dyes from (Schultz and Ichenhaeuser), A., i, 229.

o-Cresol-5-arsenic acid (Benda and Kahn), A., i, 592.

p-Cresol-3-sulphonic acid, 2-nitro-5-amino- and o-Cresol-5-sulphonic acid, 6-nitro-3-amino-, preparation of (Farbwerke vorm. Meister, Lucius, & Brüning), A., i, 785.

o-Cresolsulphonic acids, copper salts, and the action of ammonia and pyridine on (Levy and Erler), A., i, 177.

Cresorcino1 (2:4-dihydroxytoluene) dimethyl ether, aldehyde from, and its oxime, synthesis of (Gattermann), A., i, 34.

Cresoreylaldehyde and its azine, synthesis of (Gattermann), A., i, 30.

Critical opalescence. See Opalescence. temperatures and molecular weights of liquids, determination of, by the aid of drop weights (Morgan and Stevenson), A., ii, 356; (Morgan and Higgins), A., ii, 668.

of solutions (Centnerszwer), A., ii, 13.

Crops, influence of stimulating compounds on, under different conditions (Uchiyama), A., ii, 126.

farm, pot experiments to determine the limits of endurance of, for certain injurious substances (Guthrie and Helms), A., ii, 590.

Crotonaldehyde, condensation of, with malonic acid (Riedel), A., i, 501.

action of organo-magnesium compounds on, and the optical behaviour of the products (Reif), A., i, 847.

XCIV. ii.

Crotonic acid, stereochemical nature of the addition of chlorine to (Michael and Bunger), A., i, 848.

Crotonic acid, ethyl ester, action of semicarbazide on (Ruhe and Hinterlach), A., i, 13.

Crotonic acid, γ-chloro-β-amino-α-cyano-, ethyl ester (Benary), A., i, 600.

Crotonylideneacetone and its bromo-compound, oxime, phenylhydrazone, and semicarbazone (Meerwein), A., i, 90.

Crotonylidenemalonic acid (Riedel), A., i, 501.

methyl ester (Meerwein), A., i, 90.

Crotonyltropeine and its picrate (Wolffenstein and Rolle), A., i, 282.

Crucibles of iridium and rhodium, use of, in chemical operations (Crookes), A., ii, 702.

Cryalite, reversible alteration of (Cornu), A., ii, 955.

Cryometric measurements, practice of (Poda), A., ii, 564.

Cryoscope, a (Dekhuyzen), A., ii, 661.

Cryoscopic investigations of solutions of gases in liquids (Falciola), A., ii, 1013.

measurements, stand for apparatus for (Leespiau), A., ii, 564.

method, modification of the, for investigating small quantities of (Kinosita), A., ii, 810.

Crystalline form, chemical composition, hardness, and density, relation between (Pöschl), A., ii, 673.

and chemical constitution of picryl derivatives, relation between (Jerusalem and Pope), A., ii, 674.

of halogen derivatives of open-chain hydrocarbons with reference to the Barlow-Pope theory of structure (Jaeger), T., 517; P., 29.

Crystalline liquids, anomalous viscosity at the clearing point of so-called (Bose and Conrat), A., ii, 258; (Bose), A., ii, 1017.

amorphous, and colloidal states (v. Weimarn), A., ii, 90.

liquid state as a general property of matter (v. Weimarn), A., ii, 90, 283, 1023.

state as a general property of matter (v. Weimarn), A., ii, 263.

Crystallisation from aqueous solutions (Marc), A., ii, 160.

velocity of, of isomorphous mixtures (Padoa), A., ii, 89.

explosive (Weston), A., ii, 759.
Crystallisation, spontaneous, the temperatures of, of mixed solutions and their determination by means of the index of refraction (ISAAC), T., 384; P., 30.

of solutions of some alkali nitrates (JONES), T., 1739; P., 196.

of substances which form a continuous series of mixed crystals (Miers and ISAAC), T., 927; P., 125.

Crystallography of the monoxides and monosulphides of the elements of the second group (BEEKENKAMP), A., ii, 280.

of some cyclic organic compounds (JAEGER), A., i, 413.

See also Isomorphism and Polymorphism.

Crystal-systems and the optical interference-figures of liquid crystals (VORLÄNDER), A., ii, 88.

Crystals, orientation of, by the magnetic field; importance of optical properties of mixed liquids from the point of view of crystalline symmetry (COTTON and MOUTON), A., ii, 757.

natural and magnetic rotation of the plane of polarisation in (VOIGT and HONDA), A., ii, 912.

rate of growth and solution of (ANDREEFF), A., ii, 475.

causes modifying the dominant faces of (GAUBERT), A., ii, 933.

parallel growths of, and isomorphous miscibility (BARKER), A., ii, 366.

apparatus for the centrifugal draining of small quantities of (BAXTER), A., ii, 369.

helical structures (GAUBERT), A., ii, 475.

influence of temperature changes on the absorption in (BECQUEREL), A., ii, 78.

which are not enantiomorphous; rotatory polarisation in (SOMMERFELDT), A., ii, 339.

liquid, clear and transparent (VORLÄNDER and KASTEN), A., i, 641; (VORLÄNDER), A., ii, 675.

liquid (ROTARSKI), A., i, 640; ii, 675; (LEHMANN), A., ii, 1023.

formation of (VORLÄNDER), A., ii, 22.

relation between constitution and capacity for forming (VORLÄNDER and KASTEN), A., i, 641; (BOSE), A., ii, 1017.

optical interference-figures of (VORLÄNDER), A., ii, 89.

examination of, in convergent polarised light (SOMMERFELDT), A., ii, 338.

Crystals, liquid, and their mixtures, character of melting point and clearing point curves for (BOGOJAWLINSKY and WINOGRADOFF), A., ii, 809.

mixed, hardness of (KURNAKOFF and SCHEMTSCHUSCHNY), A., ii, 932.

mixed saturated, influence of the rate of cooling on the composition of (V. LEPKOWSKI), A., ii, 810.

Ctenophore swimming-plate, rôle of calcium salts in the mechanical inhibition of (LILLIE), A., ii, 310.

Cubeb, oil of (HAENSEL), A., i, 665.

Cultivation experiments, comparative investigation of the results of chemical soil analyses and of (OITZ), A., ii, 421.

ψ-Cumeneazo-orcinol, 6-bromo- (ORTON and EVERATT), T., 1020.

ψ-Cumene-4-azoresorcinol, 6-bromo- (ORTON and EVERATT), T., 1019.

p-Cumenesulphinic acid, preparation of (KNOEVENAGEL and KENNER), A., i, 971.

ψ-Cumenesulphinic acid preparation (KNOEVENAGEL and KENNER), A., i, 971.

p-Cumenesulphinic anhydride, preparation of (KNOEVENAGEL and POLACK), A., i, 971.

ψ-Cumenesulphinic anhydride, preparation of (KNOEVENAGEL and POLACK), A., i, 971.

ψ-Cumenol, coumarins from (CLAYTON), T., 2020.

Cuminalisoin (EKERANTZ and AHLQUIST), A., i, 993.

Cuminumisonecarbamdioxide (CONDUCHE), A., i, 155.

ψ-Cumylcyanamide and its carbamide and benzoyl derivative (FIERRON), A., i, 925.

1-ψ-Cumyl-2-methylbenzimazazole, 4:7-dinitro-6-hydroxy- (MELDOLA and HAY), T., 1677.

Cuprammonium salts. See under Copper.

Cupric and Cuprous salts. See under Copper.

Curare, action of, on nerve-endings (EDMUND and ROTH), A., ii, 966.

Curcumin methyl ether (CLARKE and JACKSON), A., i, 670.

Current. See under Electrochemistry.

Cutaneous respiration. See Respiration.

Cutin, cellulose, and lignin, separation of (KÖNIG; MATTHIES), A., ii, 236.

Cyanamide, preparation and supposed ammoniacal fermentation of (ULPIANI), A., i, 859.

constitution of (PALAZZO and SCELSI), A., i, 718.
INDEX OF SUBJECTS.

Cyanamide, preparation of derivatives of (BAUM), A., i, 252.
Cyanamides, formation of (FROMM and WELLER), A., i, 703.
  aromatic monatomic (PIERRON), A., i, 925.
isoCyanates. See Carbimides.
Cyanates, thio-. See Thiocyanates.
Cyanic acid, thio-. See Thiocyanic acid.
Cyanides. See under Cyanogen.
isoCyanides. See Carbylamines.
Cyanine dyes, constitution of (VONGERICHEN and HÖFCHEM), A., i, 914.
isoCyanine dyes, optical and sensitising properties of (SHEPPARD), P., 134.
Cyanogen bromide, action of, on aryllaminocetonitriles (V.BRAUN), A., i, 625.
  action of, on hydrazine (PELLIZZARI and REPETTO), A., i, 65.
  preparation of derivatives of (BAUM), A., i, 252.
Cyanogen compounds, constitution of certain (PALAZZO and SCELSI), A., i, 718.
tautomerism of (GUILLEMARD), A., i, 718.
Hydrocyanic acid (hydrogen cyanide), synthesis of (WOLTERECK), A., i, 400.
fission of, from amides of α-bromo- fatty acids accompanied by the formation of an aldehyde or ketone (MOSSLER), A., i, 133.
  mechanism of the action of (SCHROEDER), A., ii, 413.
spectrophotographic investigations on the action of, on blood (LEWIN), A., ii, 1048.
  action of, on protein katabolism (LOEWY, WOLF, and ÖSTERBERG), A., ii, 312.
  formation of, in green plants (RAVENNA and PELLI), A., ii, 217.
  transitory presence of, in ferns (GRESHOFF), A., ii, 725.
Cyanides, action of, on thiosulphonates (GUTMANN), A., i, 972.
  See also Metallic cyanides.
Cyano-group, replacement of the sulphonic group by the, in azo-compounds (LANGE), A., i, 300.
Cyanomercury salts. See under Mercury.
Cyano-. See also under the parent Substance.
Cyanuric acid, and thio-, constitution of (PALAZZO and SCELSI), A., i, 718.
Cyclic compounds, ultra-violet fluorescence of (LEY and V. ENGELHARDT), A., ii, 911.
  Cyclic groups, polycarbon, relative stability of (HENRY), A., i, 881.
Cystine, conversion of L-serine into the natural optically active (FISCHER and RASKE), A., i, 325.
  estimation of, in urine (GASKELL), A., ii, 75.
Cystinuria with diamines (THIELE), A., ii, 971.
  protein metabolism in (WOLF, SHAFFER, ÖSTERBERG, and SOMOGYI), A., ii, 717.
Cytisine and its derivatives (MAASS), A., i, 563.
Cytolysis and lipid liquefaction, relation between (KNAFFL-LENZ), A., ii, 610.
Cytosine (1-amino-2-oxypyrimidine), origin of, obtained by the hydrolysis of nucleic acids of animal origin (LEVENE and MANDEL), A., i, 376.
  action of diazobenzensulphonic acid on (JOHNSON and CLAPP), A., i, 931.
  N-alkyl derivatives, synthesis of (JOHNSON and CLAPP), A., i, 835.
  picrolonate of (WHEELER and JAMIESON), A., i, 253.
isoCytosine (2-amino-6-oxypyrimidine), picrolonate of (WHEELER and JAMIESON), A., i, 253.
Cytosine-5-carboxylamidine, synthesis of, and its additive salts (WHEELER and JOHNS), A., i, 838.

D.
Daidzu-abura. See Soja bean oil.
Damascenonic acid. See 2-Methylamino-3-methoxybenzoic acid.
Date, invertase of the (VINSON), A., ii, 413, 724.
Datura Meteloides, meteloidine from (PYMAN), T., 2077; P., 234.
Daucosterol (v. EULER and NORDENSON), A., ii, 724; (MARCHLEWSKI), A., ii, 886.
Deaminodesatin (TRAXL), A., i, 231.
Deaminoproteins (SKRAUP), A., i, 834.
Decahydrofurourene (SCHMIDT and MEZGER), A., i, 16.
Decane. See β-Dimethylecetane.
Decenyl alcohols. See Dimethyl-Δ-ocetols.
Decyl alcohol. See Tetrahydrodinalool.
Dehydracetic acid and its salts and phenylmethylhydrazide (HESSE), A., i, 390.
Dehydrocamphophenolic acid and its ethyl ester, salts, amide, and anilide (KOMPA and HINTIKKA), A., i, 852.
Dehydrocholestanedionol (oxyzcholestenediol), formation of (PICKARD and YATES), T., 1684; P., 121.
Dehydrocoryclicine from Chinese Corydalis tubers (MAKOSHII), A., i, 825.
Dehydrodeieugenol and its diacetyl and dibenzoyl derivates (COUSINS and HERISSY), A., i, 727.
Dehydrodioseugenol and its diacetyl and dibenzoyl derivates (COUSINS and HERISSY), A., i, 783.
Dehydroisotostanediol, Dehydroisotostanenedione and its phenylhydrzone, and Dehydroisotostanenedione and its dioxime (PICKARD and YATES), T., 1931; P., 227.
Dehydroisotostanetriol and its acyl derivatives (PICKARD and YATES), T., 1930; P., 227.
Delorenzite from Craveggia, Piedmont (ZAMBRONINI), A., ii, 604.
Denitrification, ten years’ experiments on, in arable soil (AMPOLA), A., ii, 525.
Densities, limiting, application of the method of, to organic vapours (GUYE), A., ii, 86.
Density, orthobaric, of homologous liquids (TER-GAZARIAN), A., ii, 666.
of the alkali and alkaline-earth iodides (BAXTER and BRINK), A., ii, 377.
of liquids below zero (TIMMERMANS), A., ii, 85.
of fused salts (ARNDT and GESSLER), A., ii, 923.
of some fused salts and their mixtures at various temperatures (LORENZ, FREI, and JABS), A., ii, 156.
of solids, use of the micro-balance for the measurement of (BRILL and EVANS), T., 1442; P., 185.
laboratory apparatus for the determination of (GREEN), A., ii, 826.
apparatus. See also Pyknometer.
See also Vapour density.
Deoxyxanthines, hydrolysis of (TAFEL and MAYER), A., i, 742.
Dephlegmator, new, for the fractionation of naphtha (HERR), A., ii, 232.
Desmotroposantonin. See under Santonin.
Desmotropy and merotropy (MICHAEL; MICHAEL and SMITH), A., i, 943; (MICHAEL and COBB), A., i, 947.
Deutero-albumose (HASLAM), A., i, 71.
Dextrin from honey from coniferous plants, molecular weight of (BARSCHALL), A., i, 767.

Dextrose (d-glucose), osmotic pressure of solutions of, at 10° (MORSE and HOLLAND), A., ii, 759.
the function of the phosphates in the fermentation of, by yeast-juice (HARDEN and YOUNG), A., i, 590.
oxidation of (NEEF), A., i, 7.
behaviour of, towards dilute sodium hydroxide (MEISENHEIMER), A., i, 319.
action of zinc dust on (LÖB), A., i, 764.
in cat’s saliva (CARLSON and RYAN), A., ii, 403.
consumption of, by mammalian cardiac muscle (LOCKE and KOSENHEIM), A., ii, 120.
derivatives, constitution of (IRVINE and GILMOUR), T., 1429; P., 186.
and sodium iodide, preparation of an anhydrous crystalline compound of (WÜLFING), A., i, 763.
Barfoed’s acid cupric acetate solution as a means of distinguishing, from lactose, maltose, and sucrose (HINKEL and SHERMAN), A., ii, 235.
detection of, in urine (OTTO), A., ii, 739.
comparative investigations on various reduction processes for the estimation of (KINOSHITA), A., ii, 437.
Dextrose-α- and -α-nitrophenyl-hydrzones and -osazones (RECLAIRE), A., i, 1014.
Dextrosephenylyhydrzones (BEHREND and LOHR), A., i, 765.
Dextrosephenylsazones, behaviour of, in the organism (PIGORINI), A., ii, 876.
Diabetes (glycosuria), production of, in rabbits by intravenous injection of sea water made isotonic with the blood (BURNETT), A., ii, 213.
action of radium emanations in (POULSSON), A., ii, 1057.
carbon dioxide in venous blood and alveolar air in cases of (BEDDARD, PEMBREY, and SPRIGOS), A., ii, 718.
experimental (MACLEOD), A., ii, 770.
morphine (SPITTA), A., ii, 972.
pancreatic, acidosis in (ALLARD), A., ii, 1058.
nitrogenous and inorganic metabolism in, in dogs (FALTA and WHITNEY), A., ii, 213.
influence of muscular work on the excretion of sugar in (SÉO), A., ii, 1058.
in selachian fishes (DIAMARE), A., ii, 519.
INDEX OF SUBJECTS.
1293

**Diabetes (glycosuria),** phloridzin, influence of diuretics on (LOEWI and NEUBAUER), A., i, 718.

excretion of sodium chloride in (BIBERFELD), A., ii, 972.

influence of cold and exercise on sugar excretion in (LUSK), A., ii, 612.

production of sugar from glutamic acid ingested in (LUSK), A., ii, 612.

salt, mechanism of (UNDERHILL and KLEINER), A., ii, 409.

**Diabetes mellitus,** prosecretin in relation to (BAINBRIDGE), A., ii, 213.

function of the pancreas in (LOEWI), A., ii, 712.

degradation of fatty acids in (BAER and BLUM), A., ii, 1057.

**Diacet.** See also Diacetyl, and under the parent Substance.

**Diacetanilide,** s-tribromo- and 2:6-dichloro-4-nitro (SMITH and ORTON), T., 1250.

**Diacetanilides,** formation of (SMITH and ORTON), T., 1246; P., 132.

**Diacetone alcohol,** aminolactones from (KOHN), A., i, 819.

**Diacetonitrile,** condensation of (V. MEYER and HENNING), A., i, 910.

action of arylamines and hydrazine derivatives on (V. MEYER, SCHUMACHER, and LEHMANN), A., i, 909.

**Diacetonitrile,** amino-, N-benzoyl derivative of (V. MEYER and LEHMANN), A., i, 910.

9:10-Diacetoxy-2-methoxybrazan (V. KOSTANECKI and LAMPE), A., i, 907.

**iacetoxy.** See also under the parent Substance.

**Diacetyl** (dimethyl diketone) monosemicarbazone and its sodium salt (BLITZ and HORMANN), A., i, 516.

4:4'-Diacetyldiphenylmethane (DUVAL), A., i, 277.

2:2'-diamino-, 2:4:2':4'-tetracaminoo- and 2:2'-dinitro- (DUVAL), A., i, 657.

**Diacetylglyoxylic acid,** action of, on aniline and its homologues (V. OSTROMISSLENSKY), A., i, 889.

**Diacetyleoximecarbazone** and its acetate (BLITZ and HORMANN), A., i, 516.

**Diacetyl.** See also under the parent Substance.

**Dialkylaminodimethylethylcarbinols** and their benzoyl derivatives, preparation of the alkyl halides of (RIEDEL), A., i, 607.

5:5-Dialkylbarbituric acids, preparation of (FARBENFABRIKEN VORM. F. BAYER & CO.), A., i, 292; (CHEMISCHE FABRIK AUF AKTIVEN VORM. E. SCHERING), A., i, 370, 1017; (EINHORN; BOEHINGER & SÖHNE), A., i, 484.

p-Dialkylbenzoximino-, dilydroxy-, synthesis of (FICHTER, JETZER, and WEISS), A., i, 659.

**Dialkyglycollic acids,** cyanamides and ureides of (CLEMMENSEN and HEITMAN), A., i, 771.

aa-Dialkyl-β-keto-alcohols (BLAISE and HERMAN), A., i, 596.

as-Dialkylmalic esters, new synthesis of (RASSOW and BAUER), A., i, 316.

**Dialkylxalacetic esters,** new synthesis of (RASSOW and BAUER), A., i, 316.

2:6-Dialkylpyrenols, preparation of carbamates of (BASLER CHEMISCHE FABRIK), A., i, 635.

**Dialkylphthalalides** (BAUER), A., i, 274.

**Dialysis.** See under Diffusion.

Diamide, dicyano. See Dicyanodiamide.

**Diaminodicarboxylic acids,** synthesis of (SÖRENSEN and ANDERSEN), A., i, 649.

**Diamond,** summary of information as to the artificial production of (THRELFALL), T., 1351; P., 131.

conversion of, into coke in high vacuum by cathode rays (PARSONS and SWINTON), A., ii, 275.

**Diosamyl sulphoxide,** preparation of (GAZDAR and SMILES), T., 1834; P., 216.

β-Diamylaminomethyl benzoate and its hydrochloride and oxalate (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 167.

**Diosamylaminomethyl** benzoate and hydrogen oxalate (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 266.

**Diosamylpiperidinium salts** (V. BRAUN), A., i, 678.

**Dianilinosoctic acid** and its rearrangement (V. OSTROMISSLENSKY), A., i, 899.

**Dianilindibenzy1** and its diacetyl and dibenzoyl derivatives (ANSELINO), A., i, 259.

**Dianilithiobuuret** (FROMM and BAUMHAUER), A., i, 702.

**Di-p-anisyl sulphoxide** (KNOEVENAGEL and KENNER), A., i, 971.

**Di-p-Dianisylamine** and its nitrosoamine (WIELAND), A., i, 1016, 1026.

**Di-p-Dianisylbutyric acid,** β-iodo-p-hydroxy-, lactone of (BOUGAULT), A., i, 533.

**Dianisylhydrazine** and its hydrochloride (WIELAND), A., i, 1026.
Dianthraquinonyldiaminostilbene (Fischer and Prause), A., i, 220.

α-Dianthraquinonyl, preparation of anthracene derivatives from (Scholl), A., i, 428.

Dianthraquinonyldiaminoanthraquinones, complex, preparation of (Badische Anilin- & Soda-Fabrik) A., i, 807.

Diastase in cat's saliva, the (Carlson and Ryan), A., ii, 606. in human saliva (MestreZat), A., ii, 606.

Scission of lactose, maltose, and their derivatives by (Bierry and Giaza), A., i, 1031.

Reactions of (Schneidewind, Meyer, and Münther), A., ii, 879. preparations, proposed method for the routine valuation of (Johnson), A., ii, 743.

Diastases, investigation of (Wohlgemuth), A., ii, 403.

Diazocetamide, action of hydrazine hydrate on (Curtius, Darapsky, and Bockmühl), A., i, 144.

Diazoeetic acid, ethyl ester, kinetics of, and the dilution law (Mumm), A., ii, 469.

Action of alkalis on (Curtius, Darapsky, and Müller), A., i, 924.

Action of hydrazine hydrate on (Curtius, Darapsky, and Bockmühl), A., i, 144.

Reaction of, with m-xylene (Bucher and Delbrück), A., i, 87.

isoDiazoeetic acid, ethyl ester, so-called (Curtius, Darapsky, and Müller), A., i, 923.

ψ-Diazoeetic acid and its salts (Müller), A., i, 922.

DiazocinotoluenoI cobaltinitritre (Hoffmann and Buchner), A., i, 876.

Diazobenzene, action of, on glutaric acid and its ethyl ester (Henrich and Thomas), A., i, 114.

p-amino-, bromide, N-acetyl derivative of (Bülow and Schmachtenberg), A., i, 744.

Diazobenzene (benzenediazonium) bromide, preparation of (Chattaway), T., 599.

perbromides, bromination by means of (Bülow and Schmachtenberg), A., i, 743.

Diazobenzene chloride, rate of decomposition of (Cain and Nicoll), P., 282.

isoDiazobenzene salts, preparation of (Stolle), A., i, 917; (Thiele), A., i, 927.

Diazochlorides, action of, on α- and γ-bromoacetacetic esters (Favrel), A., i, 209.

Diazocompounds, Cain's theory of (Hantzsch), A., i, 1021.

Behaviour of, with ketonic and enolic compounds (Tingle and Williams), A., i, 126.

isoDiazocompounds (isozoalates), aromatic and fatty, from hydrazines (Thiele), A., i, 927.

Diazogroup, position of entrance of the, in the formation of azo-dyes (Scharwin and Kaljanoff), A., i, 704.

p-Diazominobenzene, derivatives of (Morgan and Micklethwait), T., 602; P., 48.

Diazomethane, action of, on the two modifications of isonitrosocamphor (Forster and Holmes), T., 242; P., 8.

Action of, on hydroxyazo-compounds (Smith and Mitchell), T., 842; P., 70.

And alkyl haloids, reactions of, with tautomeric acids and salts (Cree, Johnson, Brunel, Shadinger, and Nirdlinger), A., i, 919.

1-Diazo-β-naphtholsulphonic acids, salts, preparation of (Badische Anilin- & Soda-Fabrik), A., i, 231.

Diazonium bromides, new general method of preparing (Chattaway), T., 955; P., 93.

perbromides, constitution of (Chattaway), P., 172.

Salts, quantitative conversion of aromatic hydrazines into (Chattaway), T., 852; P., 74.

Reaction of, with mono- and dihydric phenols and with naphthoI (Orton and Everett), T., 1010; P., 118.

Diazophenylarsonic acid and its products of decomposition (Bertheim), A., i, 591.

Diazoreaction, study of, in the diphenyl series (Morgan and Micklethwait), T., 614; P., 51.

Diazosalts, interaction of, with aromatic amides of the higher fatty acids (Sulzberger), A., i, 483.

Reaction of, with azo-dyes (Lwoff; Grandmougin), A., i, 483.

Action of, on primary dinitrohydrocarbons (Ponzio and Chabrier), A., i, 582.
INDEX OF SUBJECTS.

Diazo-salts, action of, on \(\omega\)-dinitrotoluene (Ponzio), A., i, 482.

Diazo-solutions, decomposition of (Hantzsch and Thompson), A., i, 1021.

Diazotoluene (toluenediazonium) bромides, \(\alpha\)- and \(\beta\)-, preparation of (Chattaway), T., 960.

Dibenzenesulphonimide and its salts (Haga), A., i, 870.

Dibenzenesulphonylhydroxamic acid. See Diphenylsulphonylhydroxylamine.

Dibenzo\(\alpha\)-propyridan (Decker and Fels,er), A., i, 906.

Dibenzo\(\alpha\)pyronium derivatives (Decker and Fels,er), A., i, 1003.

Dibenzoyl. See Benzil.

\(\alpha\)-Dibenzoylbenzene, amino-derivatives of (Guyot and Pignon), A., i, 569.

Dibenzoylecarbamide, \(3:3\)-di-\(p\)-bromomcco (Biltz and Rimpel), A., i, 574.

Dibenzo\(\alpha\)dimethylcarbamide (Biltz and Rimpel), A., i, 464.

3:6-Dibenzoyl-2:5-dimethylpyrazine and its dioxime (Sonu), A., i, 56.

3:4:5:6-Dibenzoylene-1-phenylenedihydrazide and its ethyl ester (Errera), A., i, 185.

\(\alpha\beta\)-Dibenzoxy-\(\alpha\)-methoxydibenzy1 and its reactions (Irvin and Mccnoll), T., 956; P., 119.

\(s\)-Di-\(\beta\)-benzoxoxy-1:4-diethylpiperazine and its additive salts and physiological action (Pyman), T., 1795; P., 208.

\(\beta\)-Dibenzoyloxyethylpropylamine and its additive salts and physiological action (Pyman), T., 1794; P., 208.

\(\beta\)-Dibenzo\(\alpha\)zoyloxydimethylpropylamine and its additive salts and physiological action (Pyman), T., 1794; P., 208.

\(s\beta\)-Dibenzo\(\alpha\)zoyloxymethyldiethylamine and its additive salts and physiological action (Pyman), T., 1794; P., 208.

\(\beta\)-Dibenzoyloxy-1-propylpiperidine and its additive salts and physiological action (Pyman), T., 1794; P., 208.

\(s\beta\)-Dibenzo\(\alpha\)zoyloxytriethylamine and its additive salts and physiological action (Pyman), T., 1794; P., 208.

Dibenzoyltartramide (Einhorn), A., i, 611.

Dibenzoyl. See also under the parent Substance.

Dibenzyl \(\delta\)isocyanide (Price and Jones), P., 134.

\(\delta\)isulphide, preparation of (Price and Twiss), T., 1399.

\(\delta\)isulphoxide, preparation of (Gazdar and Smiles), T., 1835; P., 216.

Dibenzylacetic acid, methyl ester (Dieckmam and Kron), A., i, 388.

Dibenzylaspartic acid, optically active, synthesis of (Lutz), A., i, 345.

\(p\)-Dibenzylbenzoquinone, \(d\)ihydroxy-, and its diacetate (Fichter and Weiss), A., i, 659.

Dibenzylcampholides, isomeric, and their separation (Houben and Hahn), A., i, 540.

Dibenzylthihibitedinsulphonphoric acid (Gnehm and Schönhölzer), A., i, 113.

9:10-Dibenzylidihydrophenanthrene, 9:10-\(d\)ihydroxy-, and its oxide (Zincke and Tropf), A., i, 787.

3:6-Dibenzyl-2:5-dimethylpyrazine and its additive salts (Sonu), A., i, 56.

Dibenzylidithihibitedinsulphonphoric acid and its salts (Gnehm and Schönhölzer), A., i, 113.

9:10-Dibenzyl-10-ethylidihydrophenanthrene, 9-\(d\)ihydroxy- (Zincke and Tropf), A., i, 787.

Dibenzylethyl-silicol and -silicyl oxide (Robison and Kipping), T., 449; P., 25.

Dibenzyhydroxyccmpohic acids, isomeric (Houben and Hahn), A., i, 540.

Dibenzyldenediaminostilbene (Fischer and Prause), A., i, 219.

Dibenzyldenedimethoxydiaminostilbene (Fischer and Prause), A., i, 220.

Dibenzyldenedicyclopetanone (Kauffmann), A., i, 986.

Dibenzyldiene-1:3-phenylenedihydrazine (Franzen and Eichler), A., i, 831.

Dibenzyldinepropiophenone (Wieland and Stenzl), A., i, 36.

Dibenzyldinenethiocarboxyhydrazide and \(\delta\)initro- (Stolle and Bowles), A., i, 474.

Dibenzylnalamic acid, synthesis of, and its silver salt (Lutz), A., i, 345.

Dibenzyolphosphonic acid, \(d\)ihydroxy-, ethyl ester, diphenylurethane of, and aniline salt (Vallee), A., i, 976.

Dibenzyrlongalite (Fromm and Gaupp), A., i, 970.

Dibenzyldilicols, \(\alpha\)- and \(\beta\)- (Robison and Kipping), T., 448; P., 25.

Dibenzyldilicon \(\delta\)ichloride (Robison and Kipping), T., 451; P., 25.

Dibenzyldilicone and its termolecular compound (Robison and Kipping), T., 439; P., 25.

Di-3:5-\(d\)ibromobenzylmalonic acid, ethyl ester (Wheeler and Clapp), A., i, 898.
INDEX OF SUBJECTS.

p- Di-n-butylbenzoquinone, dihydroxy-, and its diacetate (FICHTER and WEISS), A., i, 659.

Dicarboxylic salts. See under Calcium.

Dicamphorylsarinic acid and its cadmium and silver salts, and chloride (MORGAN and MICKLETHWAIT), T., 2144; P., 268.

3:4:3:4’-Di-carbonyldi-o-phényleneguanidine, (BARGER and EWINS), T., 737.

3:4:3:4’-Di-carbonyldioxy-aa-chloro-derivative (BARGER and EWINS), T., 736.

3:4:3:4’-Di-carbonyldioxy-aα-β-derivative (BARGER and EWINS), T., 740.

Dicarboxylic acid, organic, electrolytic decomposition of (VANZETTI), A., i, 889.

Dicarboxylic anhydrides, reactions of, with magnesium organic compounds (HOUHEN and HAHN), A., i, 859.

Disocarvustrene, synthesis of (FISHER and PERKIN), T., 1892.

Dicholesteryl ether, oxidation of (PICKARD and YATES), T., 1682; P., 121.

Dichroism, attempt to produce, by pressure in silver haloids (CORNU), A., ii, 647.

Dicyanodiamide (cyanoquinidine), preparation of (JONA), A., i, 143.

constitution and reactions of, and its dibenzoyl derivative (POHL), A., i, 575.

action of ethylenediamine on (DITTLER), A., i, 925.

salts of, with acid dyes (RADLBERGER), A., i, 1001.

Dicyanodiamidine, amino-, preparation of (JONA), A., i, 964.

Dicyclic system, saturated, formation of a new (SEMMER and BARTZELT), A., i, 38.

1:2-Di-p-dimethylamino-benzoyl-, -benzyl-, and -hydroxybenzyl-benzenes (GUYOT and PIGNET), A., i, 569.

Didymyum, cerium, and lanthanum, quantitative spectra and separation of (POLLOK and LEONARD), A., ii, 645.

Didymyum salts, variations of the absorption bands of, in a magnetic field (BECQUEREL), A., ii, 78.

influence of, on plants (KANOMATA), A., ii, 616.

Dielectric constant. See under Electrochemistry.

1:4-Diethanolpiperazine and its additive salts (PYMAN), T., 1802; P., 208.

Diethoxycetic acid, piperidide of (WOHL and LANGER), A., i, 943.

2:5-Diethoxybenzaldehyde, synthesis of (GATTERMANN), A., i, 34.

1:3-Diethoxybenzene. See Resorcinol diethyl ether.

Diethoxybenzozquinine (POLLAK and GOLDSTEIN), A., i, 554.

2:2’-Dioxydimethylphenyl and its dialdehyde, synthesis of (GATTERMANN), A., i, 35.

4:4’-Diethoxydiphenyl sulphonyde, preparation of (GARDAR and SMILES), T., 1835; P., 216.

Diethyl disulphide, preparation of (PRICE and TWISS), T., 1899.

Diethylacetamide, bromo-. See Neuronal.

p-Diethylaminoazobenzene, coloured salts of (HANTZSCH and HILSCHER), A., i, 485.

p-Diethylaminoazobenzenesulphonic acid and its salts (HANTZSCH and HILSCHER), A., i, 470.

p-Diethylamino-benzoyl-2-p-dimethylanilino-benzoylebenzene and its phenylhydrazone and phthalazine and benzylbenzene and trinitro- (GUYOT and PIGNET), A., i, 569.

1-p-Diethylaminobenzoyl-2-p-dimethylaminobenzylbenzene (GUYOT and PIGNET), A., i, 569.

o-Diethylaminobenzylphenytelethramethyldiaminodiphenylcarbinol and its salts, and its leuco-base (GUYOT and PIGNET), A., i, 570.

p-Diethylaminop-dimethylaminobenzylbenzhydrol (GUYOT and PIGNET), A., i, 569.

p-Diethylaminop-9-p-dimethylaminophenyl-anthracene and -dihydroanthracene (GUYOT and PIGNET), A., i, 569.

Diethylaminodiphénylmethane and its nitroso-derivative and phenylthiocarbamide (V. BRAUN), A., i, 685.

β-Diethylaminooethylyphenyl hydrochloride (MERCK), A., i, 266.

p-amino- and p-nitro-cinnamates (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 169.

benzoate and its hydrochloride, preparation of (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 167.

benzoate and picrate (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 266.
β-Diethyaminomethyl phthalate and its additive salts (Pyman), T., 1804; P., 208.
salicylate and its hydrochloride (Farbwerke vorn. Meister, Lucius, & Brüning), A., i, 176.
β-Diethylamino-α-hydroxyisobutyric acid and its ethyl ester (Les Établissements Poulenc Frères & Ernest Fourneau), A., i, 938.
Diethylenimethylenamelamide (Einhorn), A., i, 611.
4'-Diethylamin-9-phenylacridine (Ullmann, Bader, and Labhardt), A., i, 52.
Diethylenimopropyl benzoate and its picrate (Farbwerke vorn. Meister, Lucius, & Brüning), A., i, 266.
Diethyleniminosopropyl benzoate and its hydrochloride, oxalate, and picrate (Farbwerke vorn. Meister, Lucius, & Brüning), A., i, 167.
Diethylenimothiazine, dimetironisonitroso, and its salts (Gnehm and Schindler), A., i, 110.
Diethylaminophenolquinone (Fichter and Glaser), A., i, 660.
5:5-Diethylbarbituric acid, preparation of (Farrenfabrikken vorn. F. Bayer & Co.), A., i, 292; (Einhorn; Boehringer & Söhne), A., i, 464.
α-Diethylbenzen, di-a-hydroxy- (Nelken and Simonis), A., i, 348.
s-Diethylbenzidine, liquid crystals (Rotarski), A., i, 640.
p-Diethylbenzquinone, dihydroxy-, hydrolysis of (Fichter and Kappeler), A., i, 660.
Diethyl-a-camphoramic acid (Freylon), A., i, 861.
Diethylichloroisocyanine iodide (Vongercichten and Höfchen), A., i, 914.
Diethyl-β-chloroethylcarbinol (Maire), A., i, 247.
Diethylisocyanine iodide (ethyl-red) and its methiodide, formula of (Vongercichten and Höfchen), A., i, 914.
Diethyl-β-diethyaminomethylcarbinol (Maire), A., i, 248.
Diethylidihydroanthracene, dihydroxy- (Clarke), A., i, 331.
Diethylenediamine. See Piperazine.
Diethylyglycolcollamide (Mannich and Zernike), A., i, 399.
C-Diethylyglycollycyanamide (Clemmensen and Heitman), A., i, 772.
C-Diethylglycollyl-carbamide and its salts and -thiocarbamide (Clemmen sen and Heitman), A., i, 771.
1:3-Diethylglycolhexadiene (Blaise and Maire), A., i, 391.
2:3-Diethylindole and its picrate (Padoa and Chiaves), A., i, 165.
Diethylketen (Staudinger and Ott), A., i, 603.
Diethyl ketone, reaction of, with mercuric iodide in alkaline solution (Marsh and Struthers), P., 267.
Diethylnalonic acid (Tafel and Thompson), A., i, 58.
Diethylnalonic acid, derivatives of (Einhorn), A., i, 314; (Staudinger and Ott), A., i, 603.
Diethylnalonic anhryde and semi-chloride (Staudinger and Ott), A., i, 603, 939.
Diethylnalonylnphenyl-aminoguanidine and -guanidine (Einhorn), A., i, 315.
Diethylnalonyltetra-methyl- and -ethyl- dicarbamides (Einhorn), A., i, 464.
Diethylnalonylureide, methyl and ethyl esters (Boehringer & Söhne), A., i, 464.
9:10-Diethylphenanthrene (Zincke and Tropp), A., i, 787.
1:3-Diethyphthalan (Nelken and Simonis), A., i, 348.
Diethyphthalide, 5-amino-, and its acetyl derivative and platinichloride, 5-hydroxy-, and its benzoyl derivative and methyl ether, and 4:6-dimetro5-hydroxy-, and its methyl ether (Bauer), A., i, 274.
Diethylnipperidinum salts (v. Braun), A., i, 677.
Diethylsopropylmethane. See β-Methyl-γ-ethylpentane.
Diethylthiobarbituric acid, reduction of (Einhorn and v. Diesbach), A., i, 110.
Diethylthioglycollic acid and its amide (Clemmensen and Heitman), A., i, 772.
β-β-Diethylothiohydantoin (Clemmensen and Heitman), A., i, 771.
as-Diethylthionine and its reactions (Gnehm and Schindler), A., i, 112.
Diets, the relationship of dysoxidisable carbon and nitrogen on (Spiro), A., ii, 118.
Dioxofenchylcarbamide (Bouveault and Levallois), A., i, 193.
Diffusion, apparatus for the study of, in solid media (Yéguonoff), A., ii, 465.
Diffusion of colloids (Herzog and Kasarnowskij), A., i, 707.
of electrolytes in aqueous solutions and in gelatin (Vanzetti), A., ii, 20, 88.
of gaseous ions (Salles), A., ii, 931.
of metals in mercury (Smith), A., ii, 159.

See also Membranes.

Diffusion constants, internal friction, and electrical conductivity, relation between (Pissarjevsky and Karp), A., ii, 566.
of non-electrolytes in solution, calculation of (v. Wogau), A., ii, 817.

Osmotic pressure (Trevor), A., ii, 359; (Traube), A., ii, 565.
and Brownian motion (Duclaux), A., ii, 760.
and specific heat of solution (v. Bikon), A., ii, 459.
and vapour pressure of a volatile solute (Callendar), A., ii, 1019.
of strong solutions (Callendar), A., ii, 671.
improvement in cells for the measurement of (Morse and Mears), A., ii, 1019.
improved manometers for measurement of (Morse and Lovelace), A., ii, 1020.
of compressible solutions of any degree of concentration; cases in which both solvent and solute are volatile (Porter), A., ii, 670.
of concentrated solutions, and the laws of the perfect solution (Lewis), A., ii, 465; (van Laar), A., ii, 1018.
of concentrated solutions of non-electrolytes (Sackur), A., ii, 931.

Osmotic researches (Cohen and Commelin), A., ii, 811.

Dialysis, apparatus for continuous (Schevver), A., ii, 465.

Osmosis, passage of substances into the human system by (Kahlenberg), A., ii, 408.
of liquids, role of imbibition in the (Flusin), A., ii, 359.
electric. See under Electrochemistry.

Di-Q-fluorylthiocarbamide (Schmidt and Stützel), A., i, 415.

Diformaldehyde (Fromm and Gaupp), A., i, 970.

Digallie acid (Fischer), A., i, 893.

Digallide, tetra-acetyl derivative (Nie- renstein), A., i, 897.

Digestion, the chemistry of (London and Polowzowa), A., ii, 50, 870, 960, 1050; (London; London and Fewsner; London and Sulema; London and Sandberg; Dobrowolskaja; London and Wersilowa; London and Kivkind), A., ii, 870.

work of (Heilner), A., ii, 305.
effect of alcohol on (Zitowitsch), A., ii, 404.
gastric, importance of the blood in (Dobrowolskaja), A., ii, 870.
importance of the mouth in (London and Fewsner), A., ii, 870.
in fishes (van Herwerden), A., ii, 872.

Diglycinimide and its additive salts and benzoyl and chloroacetyl derivatives (Bergell and Feigl), A., i, 140.
hydrolysis of (Bergell and Feigl), A., i, 396.

Diglycollic acid, new homologues of (Jungfleisch and Godchot), A., i, 127.

Diglycollic acid, dithio-, and its esters (Price and Twiss), T., 1645; P., 198.
action of sodium hydroxide on derivatives of (Frechich and Wildt), A., i, 413.

Digitalin, physiological action of (Hulschinsky), A., ii, 520.

Digitalis, action of, on the vagus (Lhoták v. Lhotá), A., ii, 521.
and strophanthus, action of, on the heart (Tigerstedt), A., ii, 612.

Digitalis glucosides, toxic, colour reactions of (Garnier), A., ii, 544.

Digitalis group, action of, on the kidneys (Jonescu and Loewi), A., ii, 720.

Digitalis leaves, physiological assay of (Focke), A., ii, 332.

Digitojonic acid and its phenylhydrazide (Kilian), A., i, 245.

Diguaiacylphosphoric acid and its salts and chloride (Auger and Dupuis), A., i, 529.

Di-A, cyclohexanecacetic acid, a-cyano-, methyl ester (Harding, Haworth, and Perkin), T., 1957.

Dihydrazines (v. Braun), A., i, 700, 737.
2:5-Dihydrinotiazole, 1-amino-, and its tribenzylidene derivative (Stolle and Böwles), A., i, 475.

Dihydroanthracene, derivatives of (Clarke), A., i, 330.

Dihydrobenzenes. See cycloHexadienes.

Dihydrobrazilinic acid, lactone of, synthesis of (Perkin and Robinson), T., 489; P., 54.
INDEX OF SUBJECTS.

1299

Dihydrobrucinonic acid (Leuchs), A., i, 563.

Dihydrocamphoric acid, racemic, synthesis of (Bouvaulet and Locquin), A., i, 172.

Dihydrocarvone xanthate and its amide (Tsugaeff), A., i, 238.

Dihydroisoascarvenol (Δ\(^2\)-m-menthenol (8)) and its nitrosochloride, synthesis of (Fisher and Perkin), T., 1887; P., 223.

Dihydrocarvone, action of light on (Clamanian and Silber), A., i, 555. action of magnesium methyl halides on (Rupe and Emmerich), A., i, 433.

Dihydrocholesterol (cholestanol) and its acetate (Willstätter and Mayer), A., i, 636.

Dihydrocyclopentadiene, nitro-, nitrite of, nitrohydroxy-, and its sodium salt, and \(\psi\)-nitrol and nitroanitrososo- (Rule), T., 1561; P., 175.

Dihydrocycloleksantsalane (Semmler), A., i, 434.

Dihydrocysantsyal chloride (Semmler), A., i, 434.

Dihydroflavanthren and its hydroxy, hydrochloride, and \(\alpha\)-benzoyl derivative (Scholl and Holdemann), A., i, 696.

Dihydrohematoxylinic acid, lactone of, synthesis of (Perkin and Robinson), T., 439; P., 54.

cycleDihydromycene, synthesis and structure of (Tiffeneau), A., i, 500.

Dihydro-1′:2′-naphthaquinoxaline, 2-hydroxy (Lange), A., i, 839.

Dihydro-oeimene tetrabromide (Enklaar), A., i, 664.

Dihydrophytol (Willstätter and Mayer), A., i, 383.

1:2-Dihydroquinoxaline, 3-hydroxy-, and its derivatives (Motylewski), A., i, 370.

Dihydroquinoxalines, 2-hydroxy-, preparation of (Lange), A., i, 839.

Dihydro-4-stilbazole, 2-amino-, and its additive salts (Löwensohn), A., i, 51.

Dihydrostrychinonic acid (Leuchs), A., i, 564.

1:2-Dihydro-1:2:4:5-tetrazine-3-carbonylic acid and nitroso-, and their salts (Müller), A., i, 923.

Dihydrotetrazinedicarboxylic acid, bromo-, potassium hydrogen salt of (Müller), A., i, 923.

Dihydrotoluene. See Methylecyclohexadiene.

Dihydroxetetra-aquochromium sulphate. See under Chromium.

2:5-Dihetrahydroxybutylpyrazine. See Levulosazine.

\(\Delta^4\)-Dihydro-\(p\)-xylene. See 1:4-Dimethyl-\(\Delta^3\)-cyclohexadiene.

\(\alpha\)-Diketobutyric acid, \(\alpha\)- and \(\gamma\)-bromo-, esters, \(\alpha\)-phenylhydrazone and \(\alpha\)-tolylhydrazones of (Favrel), A., i, 209.

4:6-Diketo-5:5-diethylhexahydropyrimidine (Tafel and Thompson), A., i, 58.

and its mercourichloride (Einhorn), A., i, 315.

4:4′-Diketo-2:3′-dimethyltetrahydro-3:3′-quinazoyl, 7:7′-dinitro- (Bogert and Klaber), A., i, 467.

3:5-Diketo-1-ethylpyrrolidine, 4-cyano-, and its ammonium salt (Benary), A., i, 601.

Diketo-\(s\)- and -as-\(\alpha\)-naphthazines and their monoximes (Fischer and Schindler), A., i, 221.

Diketone, \(C_5H_4O_3\) and its dioxime and disemicarbazone (Semmler; Semmler and Bartelt), A., i, 38.

Diketones, aromatic, hydrogenation of (Sabatier and Mailhe), A., i, 36.

\(\beta\)-Diketones, condensation of, with carbamide (De Haan), A., i, 577.

1:5-Diketones (Rabe, Ehrenstein, and Jahn), A., i, 553.

Diketones. See also Ketones and Triketone.

2:6-Diketopiperazene (Jongkees), A., i, 959.

2:5-Diketopiperazines, degradation of, in the organism of rabbits (Abderhalden), A., ii, 521; (Abderhalden and Wacker), A., ii, 1052.

2:5-Diketopiperazine-1:4-diacyclic acid and its ethyl ester and amide (Jongkees), A., i, 959.

3:5-Diketopyrroolidine, 4-cyano-, and its silver salt and amide (Benary), A., i, 601.

4:5-Diketo-1-tolyl-2-methylpyrroolidine (Simon), A., i, 688.

Diketo-. See also Diecarybonyl.

Dilactyllic acid, \(\alpha\)- and \(\beta\)-dithio-, and their esters (Price and Twiss), T., 1645; P., 198.

Dilactyl acidis, thio-, optically active (Lovén), A., i, 714.

Dimenthyldimethylene ether, preparation of (Lingner), A., i, 351.

Di-p-methoxydiaminostilbene and its picate and diacyl derivatives (Fischer and Prause), A., i, 220.

3:5-Dimethoxyanilnine, 2:6-dinitro-(Blanksmia), A., i, 979.

Dimethoxyantraquinone, trihydroxyl (Bentley and Weizmann), T., 433; P., 52.
2:4-Dimethoxybenzaldehyde, synthesis of, and its azine and oxime (Gattermann), A., i, 33.

2:5-Dimethoxybenzaldehyde, synthesis of (Gattermann), A., i, 34.

3:4-Dimethoxybenzaldehyde. See Veratraldehyde.

1:2-Dimethoxybenzene. See Veratrole.

1:3-Dimethoxybenzene. See Resorcinol dimethyl ether.

1:4-Dimethoxybenzene. See Quinol dimethyl ether.

3:4-Dimethoxybenzene-1,2-dicarboxylic acid. See Hemipinic acid.

3:4-Dimethoxybenzoic acid, dinitro-, ethyl ester (Wegscheider, Müller, and Chiari), A., i, 897.

o-Dimethoxybenzoin, alkylation of (Irvine and McNicol), T., 1607; P., 192.

2':4'-Dimethoxybenzoylbenzoic acid, preparation of (Perkin and Robinson), T., 510.

3:5'-Dimethoxy-4-benzoylcoumaran (v. Kostanecki and Lampe), A., i, 442.

2:4-Dimethoxybenzylpropionic acid and its methyl ester, and the condensation of the ester with ethyl oxalate (Perkin and Robinson), T., 506.

2:4-Dimethoxybenzylpyruvic acid, ethyl ester, preparation of (Perkin and Robinson), T., 505.

2:4-Dimethoxybenzylamine. See Veratrylamine.

3:5'-Dimethoxy-4-benzoylcoumaran (v. Kostanecki and Lampe), A., i, 442.

2':4'-Dimethoxybenzylideneacetophenone, 2-hydroxy-; and the action of hydrochloric acid on, and its potassium derivative (Perkin, Robinson, and Turner), T., 1109.

5:6-Dimethoxy-2-benzylidene-1-hydrindone, 2':4'-dihydroxy- (Engels, Perkin, and Robinson), T., 1154.

5:6-Dimethoxy-2-chloromethylene-1-hydrindone (Engels, Perkin, and Robinson), T., 1153.

6:7-Dimethoxy-2'-mp-dimethoxyphenyl-a-naphthol and its alkali salts, and azo-dyes from (Decker), A., i, 806.

3:5-Dimethoxydiphenylamine, 2:6-dinitro- (Blanksma), A., i, 979.

2:2'-Dimethoxydiphenyl-5:5'-dialdehyde, synthesis of (Gattermann), A., i, 35.

5:6-Dimethoxy-2-hydroxymethylene-1-hydrindone (Engels, Perkin, and Robinson), T., 1153.

4:5'-Dimethoxy-2:3-indenobenzopyranol (1:4) and 7-hydroxy-, salts of (Perkin and Robinson), T., 1105.

7:4'-Dimethoxy-4:3-indenobenzopyranol (1:4), 5'-hydroxy-, salts of (Engels, Perkin, and Robinson), T., 1147.

3:5-Dimethoxymethylalaniline, 2:6-dinitro- (Blanksma), A., i, 979.

4:5-Dimethoxy-2-methylbenzaldehyde and its azine and oxime, synthesis of (Gattermann), A., i, 34.

2:4-Dimethoxy-6-methylbenzoylacetoephene (Tambor), A., i, 350.

3:4'-Dimethoxy-7-methylflavone, 5-hydroxy-, and its sodium salt (Tambor), A., i, 359.

2:6-Dimethoxyphenyl carbamate (Basler Chemische Fabrik), A., i, 635.

p-Dimethoxyphenyl sulphide and sulphoxide (Smiles and Le Rossignol), T., 760.

Bader, and Labharit), A., i, 52.

\rho\text{-}Dimethylaminophenylarsenic acid 
(dimethylatolxy) and its sodium salt 
(Michaelis), A., i, 590.

Dimethylaminophenyl-o-phenylthio- 
carbamide, cyano- (Fromm and Wel- 
ler), A., i, 703.

1:2-p-Dimethylaminophenyl-1:2-di- 
hydroisozenzofuran (Guyot and Pij- 
et, A., i, 569.

Dimethylaminophenylidimethylcarbinol 
and its benzoyl derivative and their 
salts (Riedel), A., i, 957.

4-Dimethylamino-1-phenyl-2:3-di- 
methyl-5-pyrazolone (pyramidone), 
preparation of (Farbwerke vorm. 
Meister, Lucius, & Brüning), A., 
i, 471; (Scherillen), A., i, 1010.

\rho\text{-}Dimethylamino-\beta\text{-}phenylpropionic 
acid (Weil), A., i, 982.

Dimethylaminophenyl-thiuret hydri- 
dioxide and -dithiobiuret and its hydro- 
chloride (Fromm and Weller), A., i, 
703.

Dimethylaminoisopropyl benzote 
(Chemische Fabrik auf Aktien 
vorm. E. Schering), A., i, 260.
2:5-Dimethylbenzaldehyde, Dimethylamino-oxyl.

Dimethylaminotrimethylcarbinol and the hydrochloride of its benzoyl derivative (Riedel), A., i, 356.

Dimethylisooxybenzilcarbinol, amino (Riedel), A., i, 251.

αβ-Dimethylamylene αβ-oxide (Riedel), A., i, 536.

Dimethylaniline, compound of, with iodoacetamide (v. Braun), A., i, 629.

2:5-Dimethylbenzylamine, hydroxy-, simultaneous condensation (Auger), A., i, 278.

Dimethylaniline, 3-chloro-4-amino-, preparation of (Farbenfabriken Vorm. F. Bayer & Co.), A., i, 779.

2:4-dinitro-, preparation of (Ullmann), A., i, 626.

Dimethylanthracenes, 1:6- and 2:7-, simultaneous production of (Lavaux), A., i, 150, 256.

Dimethylnarsenic acid, action of alkalis on, and its iodo-derivatives (Auger), A., i, 516.

Dimethylaxoyl. See p-Dimethy lamino-phenylarsinic acid.

2:5-Dimethylbenzaldehyde, 3-nitro-4-hydroxy-, and its azine, oxime, and condensation product with aniline (Gattermann), A., i, 29.

4:5-Dimethylbenzaldehyde, 2-hydroxy-, and its azine and phenylhydrazone, synthesis of (Gattermann), A., i, 29.

Dimethylbenzaldehydes, 2:3-, 2:5-, 2:6-, and 3:5-, 4-hydroxy-, and their derivatives, synthesis of (Gattermann), A., i, 28.

Dimethylbenzanthrone, preparation of (Badische Anilin- & Soda-Fabrik), A., i, 993.

1:3-Dimethylbenzene-4-sulphonic acid. See m-Xylene-4-sulphonic acid.

3:5-Dimethylbenzophenone, 4-hydroxy-(Auwers and V. Markovits), A., i, 630.

Dimethylbrazilin (Engels, Perrin, and Robinson), T., 1132.

βy-Dimethylbutane, nitration of, and its amine (Konovaloff), A., i, 241.

1:3-Dimethylcylobutane, 2:4-dicyano-(v. Meyer and Henning), A., i, 911.

αα-Dimethybutyratic acid, γ-bromo-, preparation of (Blanc), A., i, 245.

β-iodo-γ-hydroxy-, lactone of (Bougault), A., i, 537.

Dimethylcarnpholide and its isomeride (Komppa), A., i, 352.

Dimethylcarbamidoxime. See Acet-carbamicacidoxime.

2:6-Dimethylcarbazole and its piperate (Borsche, Witte, and Bothe), A., i, 367.

3:4-Dimethylcarbontobenzoic acid and its chloride and hydroxy-derivative (Fischer), A., i, 892.

1:4-Dimethyl-1-trichloromethylketonyclohexadiene, 4-hydroxy-, and its bromo-derivatives (Zincke and Schwabe), A., i, 337.

2:5-Dimethylcinnamic acid, 4-hydroxy-(Gattermann), A., i, 29.

β-5-Dimethyl-α-coumaric acid (Fries and Klostermann), A., i, 822.

2:5-Dimethylcoumaric acid and its ethyl ester (Fries and Fickewirth), A., i, 825.

3:4-Dimethylcoumarin (Peters and Simonis), A., i, 340.

4:7-Dimethylcoumarin and its additive salts, oxime, and phenylhydrazide (Clayton), T., 528; P., 26.

coumarone and hydrocoumarone derivatives from, and its 3-bromo-derivative (Fries and Fickewirth), A., i, 824.

3:5-Dimethylyctosine (Johnson and Clapp), A., i, 836.

Dimethylhydrodiosgenenol (Cousin and Herissery), A., i, 783.

Di-m-methyldianilinodibenzyl, di-o-hydroxy-, and its tetra-acetyl derivative (Anselmino), A., i, 259.

Dimethyldihydrobenzenes. See Dimethylyclohexadienes.

αα-Dimethyl-αβ-dihydrogeranic acid. See ααββ-Tetramethyl-Δε-octenoic acid.

9:10-Dimethyldihydrophenanthrene, 9:10-dihydroxy-, and its oxide and chloride (Zincke and Tropp), A., i, 786.

1:1-Dimethyldihydrosorcin ethyl ether, preparation and reduction of (Crossley and Renouf), T., 640.

Dimethyl diketone. See Diacetyl.

1'4'-Dimethyldiphenylamine, 1'2'-dihydroxy- (Cassella & Co.), A., i, 417.

Dimethyldipropylarsenium iodide and its compound with mercuric chloride (Dehn and Wilcox), A., i, 722.

Dimethylethylcarbinol, amino-, and its divaleryl and dibromovalerly derivatives and hydrochloride (Riedel), A., i, 250.
Dimethylethylcarbinol, amino-, and its hydrochloride, and di-isovaleryl, and dibromoisovalerylderivatives (Riedel), A., i, 769.

4:7-Dimethyl-3-ethylcoumarin (Fries and Klostermann), A., i, 822.

Dimethylethylcyclohexenone, synthesis of (Crossley and Gilling), P., 281.

Dimethylethyl-β-hydroxy-β-methylbutylammonium bromide and iodide and their benzoyl derivatives (Riedel), A., i, 607.

β-β-Dimethy1-γ-ethylpentane-α-diol and its acetate and urethane (Letellier), A., i, 242.

β-β-Dimethy1-γ-ethyl-Δ13-2-hexene (Letellier), A., i, 242.

2:5-Dimethyl-3-ethylpyrrole-4-carboxylic acid, ethyl ester, synthesis of (Korschun), A., i, 564.

3:5-Dimethyl-2-ethyl-4:6-pyronone (Wedekind and Haeussermann), A., i, 671.

2:7-Dimethylfluoran, quinonoid ester salts of (Green and King), A., i, 1003.

2:5-Dimethylfurane-3-carboxylic acid, tetrabromo- (Trephilieff), A., i, 735.

αα-Dimethylgeranic acid and its ethyl ester (Tiffeneau), A., i, 500.

C-Dimethyl-glycolycinamid e and -glycolylcarbamid e and its double salts (Clemmensen and Heitman), A., i, 771.

Dimethylglycoluril, isomerides, and their separation (Weitzner), A., i, 841.

4:5-Dimethylglyoxaline and its diaacetate (Biltz and Horrmann), A., i, 56.

Dimethylglyoxime, preparation of (Gardiner), A., i, 400.

Dimethylguanidines, αβ- and ββ-, picrolonates and picrates of (Wheeler and Jamieson), A., i, 253.

3:5-Dimethylcycloheptane-γ-carbolactone and -carboxylic acid and its amide and silver salt (Buchner and Delbrück), A., i, 88.

3:5-Dimethylcycloheptane-Δ3,5-heptatriene-1-carboxylic acids (Buchner and Delbrück), A., i, 87.

Δ9-Dimethyl-Δ9-hept-8-en-1-ol (Gry), A., i, 307.

1:4-Dimethyl-Δ13-cyclohexadiene, formation of, from dichloro-αβ-pulunenene, and its 2-carboxylic acid (Auwers and Hessenland), A., i, 561.

Dimethyl-Δ24-cyclohexadienes, 1:3- and 1:4- (Zelinsky and Gorsky), A., i, 722.

1:4-Dimethyl-Δ13-cyclohexadiene-2-carboxylic acid and its methyl ester (Auwers and Hessenland), A., i, 551; (Brühl), A., ii, 1003.

3:5-Dimethy1hexahydrotriazine, 1-imino-6-cyano-, and its picrate and nitrosoderivative (Pohl), A., i, 576.

β5-Dimethy1hexane (methylethy1isobutylmethane) (Clarence), A., i, 593.

1:3-Dimethy1cyclohexan-1-ol-3-carboxylic acid and its calcium salt and lactone (Rupe and Liechtenhan), A., i, 390.

β5-Dimethy1-β- and -β-hexanols (Clarence), A., i, 593.

1:1-Dimethy1cyclohexan-5-one and its 2 (or 4)-benzylidene derivative (Blanc), A., i, 655.

1:4-Dimethy1cyclohexan-2-one and its semicarbazon e (Harding, Haworth, and Perkin), T., 1970.

1:1-Dimethy1-Δ4-cyclohexene (1:1-dimethyl-Δ4-tetrahydrobenzene), 3-carboxy- (Crossley and Renouf), T., 641.

1:2-Dimethy1cyclohexene and 1:4-Dimethy1-Δ4-cyclohexene and its dibromide (Zelinsky and Gorsky), A., i, 722.

1:3-Dimethy1cyclohexene and its dibromide (Zelinsky and Gorsky), A., i, 722.

1:4-Dimethy1-Δ1-cyclohexene-2-carboxylic acid, 3-chloro- (Auwers and Hessenland), A., i, 551.

1:1-Dimethy1-Δ4-cyclohexen-3-one-5-acetic acid, ethyl ester, and its semicarbazon e (Crossley and Gilling), P., 130.

1:3-Dimethy1-Δ6-hephen-5-one-π-nitrophenylhydrazone (Borsche, Witte, and Bothe), A., i, 367.

Di-methylhydrobenzoin, di-o-hydroxy-, diacetylhydride of (Anselmino), A., i, 259.

β4-Dimethy1-o-hydrocumarine acid (Fries and Fickewirth), A., i, 824.

2:5-Dimethy1hydrocumarilic acid (Fries and Fickewirth), A., i, 825.

3-[2:5-Dimethy1hydrocumarilyl]-4:7-dimethy1coumarin (Fries and Klos- termann), A., i, 822.
1. [2:5-Dimethylhydrocumarinyl]-2:5-dimethylhydrocumarone and its hydrobromide, oxime, and phenylhydrazone and its methoxy and ethoxy derivatives, and its isomeride (Fries and Klostermann), A., i, 822.

4:7-Dimethylhydrocumarin (Fries and Pickewirth), A., i, 824.

2:5-Dimethylhydrocumarone (Fries and Pickewirth), A., i, 825.

1:3-Dimethylhydrothymine, 5-bromo-4-hydroxy- (Johnson and Clapp), A., i, 836.

1:3-Dimethylhydrouracil, 5-dibromo-4-hydroxy- (Johnson and Clapp), A., i, 836.

1:3-Dimethyl-7-β-hydroxyethylxanthine (Farbenfabriken vorm. F. Bayer & Co.), A., i, 475, 703.

3:7-Dimethyl-1-αβ-diβ-hydroxypropylxanthine (Farbenfabriken vorm. F. Bayer & Co.), A., i, 475.

2:3-Dimethylindoline and its oxalate (Carrasco), A., i, 913.

d-Methylinoxy, presence of, in the latex of Melaboea from Sumatra, and its tetra-acetyl derivative (de Jong), A., i, 952.

Dimethylisatin, 4-6- and 5-7-, and their phenylhydrazones (Heller and Leyden), A., i, 218.

Dimethylketolsemicarbzone (Biltz and Horrmann), A., i, 516.

Dimethylmalonic acid, derivatives of (Einhorn), A., i, 314.

Dimethylmalonic anhydride and semichloride (Staudinger and Ott), A., i, 603.

αα-Dimethylαα-α-methylidiglycollic acid and its ethyl ester, diamide, and anhydride (Jungfleisch and Godchot), A., i, 123.

Dimethylmethylene-cyclopropane, reduction of (Zelnisky), A., i, 15.

Dimethylphthalurhodine, change of the colour of fluorescence of, with the solvent (Ley and V. Engelhardt), A., ii, 748.

3:3-Dimethyl-αα- and βα-paphthindolines and their methyl ethers and acetyl derivatives (Liebert), A., i, 682.

1:3-Dimethylcyclo-[1:3:3]nonane, -nonan-5-ol-7-one and its oximes and amines, and -nonan-5-7-diol (Rabe and Jahr), A., i, 554.

3:5-Dimethyl-αα-norcardiene-7-carboxylic acid (Bucbner and Delbrück), A., i, 87.

ββ-Dimethylstere (Willstätter and Mayer), A., i, 383; (Enklaar), A., i, 664, 934.

ββ-Dimethyloctan-γ-col. See Tetrahydroinalool.

ββ-Dimethyloctan-ε-ononic acid, oxime, ψ-nitrophenylhydrazone, and semicarbazone of (Clarke, Lapworth, and Wechsler), T., 37.

ββ-Dimethyl-ΔΔ-β-oxan-γ-col (Enklaar), A., i, 934.

γγ-Dimethyl-ΔΔ-oxan-δ-ol (Abelmann), A., i, 2.

δδ-Dimethyl-ΔΔ-oxan-δ-ol (Gry), A., i, 307.

Dimethylolcarbamide (Einhorn and Hamburger), A., i, 142.

Dimethylxalic acid, ethyl ester, semicarbazone of (Rassow and Bauer), A., i, 316.

ββ-Dimethylpentane, nitration of, and its amine (Konowaloff), A., i, 241.

1:1-Dimethylcyclopentanone and 2-bromo- and 2-iodo- (Kijner), A., i, 885.

1:2-Dimethylcyclopentane (Kijner), A., i, 885.

ββ-Dimethylpentan-αα-diol and its acetate (Letellier), A., i, 242.

γγ-Dimethyl-ββ-pentanediureide (de Haan), A., i, 578.

1:1-Dimethylcyclopentan-2-ol-3-acetic acid (Blanc), A., i, 171.

2:4-Dimethylcyclopentan-2-acetic acid, lactone of (Blanc), A., i, 20.

1:1-Dimethylcyclopentan-4-one and its semicarbazone (Blanc), A., i, 655.

1:1-Dimethylcyclopentan-5-one and its oxime and 4-benzylidene derivative (Blanc), A., i, 655.

1:1-Dimethylcyclopentan-2-one-3-acetic acid and its esters, oxime, and semicarbazone (Blanc), A., i, 171.

1:1-Dimethyl-ΔΔ-cyclopentene, formation and reduction of (Kijner), A., i, 865.

1:2-Dimethyl-ΔΔ-cyclopentene, formation, structure, and oxidation of (Kijner), A., i, 530, 865.

9:10-Dimethylphenanthrene (Zincke and Tropp), A., i, 787.

Diphenacylaetic acid, formation of (Bougault), A., i, 796.

Diphenacylamine and its additive salts and nitroso-derivative (Gabriel and Lieck), A., i, 466.

Diphenacylaniline (v. Braun), A., i, 629.

Diphenanthracidine, preparation of (Austin), T., 1764; P., 200.

Diphenetyl sulphoxide. See 4:4'-Diethoxydiphenyl sulphoxide.

Di-p-phenetyl-α-disulphone (Hilditch), T., 1527; P., 192.

Diphencic acid, dinitroamino- (Schmidt and Sölfl), A., i, 997.

disulphide, 4:6:4':6-tetra-bromo- and -chloro-2:2'-dinitro- (Blanksma), A., i, 147.

sulphoxide, 4:4'-diamino-, preparation of (Gazdar and Smiles), T., 1835; P., 216.

N-diacetyl derivative of (Hinsberg), A., i, 875.

isodinitro-, derivatives of (Smiles and Hilditch), T., 1691; P., 193.

telluride dichloride (Lyons and Bush), A., i, 417.

Diphenyl, p-diamino-. See Benzidine.

3:3'-diamino-6:6'-dihydroxy-, and its hydrochloride, and 3:3'-dinitro-6:6'-dihydroxy-, and its methyl and ethyl ethers (Hale and Robertson), A., i, 635.

diiodo-, dichloride of, and its compound with benzidine (Fecht), A., ii, 913.

Diphenylacetaoilide, imide chloride of (Staudinger), A., i, 654.

Diphenylacetic acid, 4:4'-diamino- (V. OstromiKlesKsky), A., i, 889.

hydroxy-. See Benzelic acid.

αα-Diphenylacetic acid, synthesis of (Eykman), A., i, 795.

Diphenylacetoxymethane, tetachloro-p-dihydroxy-, and its sodium salt (Zincke and Birschel), A., i, 782.

Diphenylacetylene-diacetone and its diacetyl-derivative (Biltz and Horrmann), A., i, 63.

di-p-bromo-, and its glycol (Biltz and Rimpel), A., i, 574; (Biltz), A., i, 575.

Diphenylacetylphosphamic acid, chloro-, methyl ester and chloride of (Steinkopp and Benedek), A., i, 963.

ββ-Diphenylacrylic acid. See β-Phenylcinnamic acid.

Diphenylamine derivatives, preparation of (Goldberg), A., i, 288; (Ullmann and Dahmen), A., i, 975.

acetyl and -m-, and p-nitro-derivatives of (Goldberg and Siessoff), A., i, 17.

calcium derivative (Erdmann and van der Smissen), A., ii, 588.

hydroxrolides (Weinland and Reischle), A., i, 974.

2-p-phenetysulphoxide, di-p-nitro- (Smiles and Hilditch), T., 153.

Diphenylamine, p-amino-, and its derivatives, preparation of (Ullmann), A., i, 457.
Diphenylamine, 2-amino-4'-hydroxy- (ULLMANN and FUKIN), A., i, 298.

Diphenylaminonaphthylmethyl-sulphonic acid, sodium salts, and their dibenzyl ethers (SCHULTZ and ICHENHAEUSER), A., i, 230.

α-Diphenylbutadiene, addition of nitro-groups to (WIELAND and STENZL), A., i, 518.

α-nitro- (WIELAND and STENZL), A., i, 36, 518.

Diphenylbutadienediamine (WIELAND and STENZL), A., i, 518.

Diphenylbutane, di-p-hydroxy-, and its dibenzoyl derivative and dimethyl ether (LUNJAK), A., i, 416.

Di-α-phenylbutoxyamine and its hydrochloride (BUSCH and LEEFEHEL), A., i, 152.

α,α-Diphenyl-α,α-butyline, α,α-dinitro- (WIELAND and STENZL), A., i, 35.

β,γ-Diphenylbutyric acid, γ-cyano- (avery and mcdole), A., i, 544.

Diphenylcarbamic acid, calcium salt (Erdmann and van der Smissen), A., ii, 589.

Diphenylcarbamide, action of, on acids (HERZOG and HÁNCU), A., i, 268.

o-chloro- (MICHAEL and COBB), A., i, 249.

2-β-Diphenyl-4-cinnamylpyridine, 3-cyano- (v. MEYER and IRMSCHER), A., i, 912.

Diphenylbenzylaminobluet (MICHAELIS), A., i, 471; (MILRATH), A., i, 581.

Diphenylbenzylcarbazide (MILRATH), A., i, 581.

Diphenylbenzyltriazan (MICHAELIS), A., i, 471; (Goldschmidt), A., i, 572.

Diphenylbenzylidenebutyrophenone and bromo- (KLEMMER and REYNOLDS), A., i, 989.

Diphenylbenzylidenehydrazine (MICHAELIS), A., i, 471; (Goldschmidt), A., i, 572.

Diphenylbisazoescosyl and their ethers (SCHULTZ and ICHENHAEUSER), A., i, 230.
3:6-Diphenyl-4:5-dihydropyridazine-4-carboxylic acid and its ethyl ester, synthesis of (PAAL and KÜHN), A., i, 57.

2:6-Diphenylidihydropyridine, 3:5-di-cyano- (V. MEYER and KLEINSTÜCK), A., i, 910. 

as-Diphenyldimethylamine. See Methylbenzhydrylamine.

3:6-Diphenyl-2:5-dimethyl-2:5-dihydropyrazine and its hydrochloride and oxalate (GABRIEL and LIECK), A., i, 466.

3:6-Diphenyl-2:5-dimethyl-3:6-dihydropyrazine and its hydrochloride (GABRIEL and LIECK), A., i, 466.

Diphenyldimethylidenediamine, w-cyano- (V. BRAUN), A., i, 626.

4:5-Diphenyl-1:3-dimethylglyoxalene (BILTZ and HORMANN), A., i, 57. 

4:5-di-cyano-, and 4:5-oxide (BILTZ, HORMANN, and RIMPEL), A., i, 219; (ANGELI), A., i, 462.

s-Diphenylidimethyldenediamine (V. BRAUN), A., i, 685.

s-Diphenylidimethylpentamethylenediamine (V. BRAUN), A., i, 678.

3:6-Diphenyl-2:5-dimethylpyrazine (GABRIEL and LIECK), A., i, 466.

as-Diphenyl-γ-diphenylmethylen-D₅₈- pentadiene and its tetrabromide and chloro-derivative (STAUDINGER), A., i, 411.

Diphenyl-a-diaisonphene (HILDTICH), T., 1526; P., 192.

Diphenylene oxide, derivatives of (BORSCH and BOTE), A., i, 528. 

disulphide (thiacathren), constitution of (DEUSS), A., i, 635.

Diphenylene glycollic acid, 3-nitro- (SCHMIDT and SÖLL), A., i, 997.

Diphenyleketonetriaarbylic acid (BÜCHER), A., i, 792.

Diphenylenepropylene and its dibromide and ozonide, formation of (DAUFRESNE), A., i, 165.

Di-a-phenylethylamine and its derivatives (BUSCH and LEFHEM), A., i, 152.

s- Diphenylethylamine. See Stirbene.

Diphenylenelimine and its salts (BRUNNER and HAPIN), A., i, 863.

5:5-Diphenyl-3-ethylhydantoine (BILTZ and RIMPEL), A., i, 463.

ββ-Diphenyl-α-ethylpropionic acid, synthesis of, and its amide and anilide (ÉYKMAN), A., i, 796.

Diphenylethylsilicy chloride and oxide (MARSSEN and KIPPING), T., 207; P., 12.

Diphenylfurazan (WIELAND and SEMPER), A., i, 108.

aβ-Diphenylglutartic acid and its silver salt and anilide (AVERY and MCDOLE), A., i, 344.

Diphenylglycollic acid. See Benzilic acid.

Diphenylglyoxaline, bromination of (BILTZ and RIMPEL), A., i, 573; (BILTZ), A., i, 575.

Diphenylhexatriene and allied hydrocarbons, synthesis and refractive power of, and its hexabromide (SMEDLEY), T., 372.

5:5-Diphenylhydantoin and di-p-bromo-, preparation of, and their acetyl derivatives (BILTZ and RIMPEL), A., i, 463; (BILTZ), A., i, 575.

Diphenylhydroxycacetic acid, action of, on dimethylcarbamide (ANGELI), A., i, 462.

as-Diphenylhydroxy carbamide, constitution of, and its hydrate, sodium salt, and compound with acetaldehyde (CONDUCÉ), A., i, 155.

Diphenyl-2-hydroxy-9-phenylanthracene-acetic acid, lactone of, and its dimethyl and trinitro-derivatives and potassium salts (V. LIEBIG and KEM), A., i, 449.

Diphenylketen, preparation of quinonoid hydrocarbons from (STAUDINGER), A., i, 410.

coloured hydrocarbons from (STAUDINGER), A., i, 411.

Diphenylmethane, oxidation of (LAW and PERKIN), T., 1637; P., 195.

Diphenylmethane, p-diamino-, condensation of, with chloroacetic acid (NEUMÜLLER), A., i, 369.

2:2'-diamino-4:4'-dicyano-, 2:2'-dinitro-4:4'-diamino-, N-diacyl derivative of, and 2:2'-dinitro-4:4'-dicyano- (DUVAL), A., i, 683.

ψ-pentabromo- and ψ-pentachloro-p-dihydroxy-, and its dicate (ZINCKE and BIRSCHEL), A., i, 782.

Diphenylmethane carboxylic acid, 2:4- and 2:5-dihydroxy-, lactones of (V. LIEBIG), A., i, 727.

4:4'-Diphenylmethanediglycine and 3:3'-dinitro- (NEUMÜLLER), A., i, 369.

Diphenylmethanedimethylhydrazine (4:4'-bismethyldihydrizinodiphenylmethane), a reagent for characterising aldehydes, and its derivatives (V. BRAUN), A., i, 700.

reaction of, with ketones (V. BRAUN), A., i, 700.

reaction of, with cyclic ketones (V. BRAUN), A., i, 737.

Diphenylmethane series, amino-oxides of lenco-bases of the (HAMBERRGER and RUDOLF), A., i, 1011.
INDEX OF SUBJECTS.

1309

Diphenylmethylmethoxymethane, tetrabromo-p-dihydroxy-, and tetrachloro-p-di-hydroxy, and its diacetate (ZINCKE and BIRSCHEL), A., i, 782.

2:6-Diphenyl-4-p-methoxyphenylpyridine, 3-cyano- (V. MEYER and IRMUCKER), A., i, 912.

Diphenylmethyl d-sulphide (BIILMANN), A., i, 143.

dithiolecarbonate (BIILMANN), A., i, 143.

aa-Diphenyl-3-methyl-6-amyylene (SCHORIGIN), A., i, 866.

2:6-Diphenyl-4-methylidihydropyridine, 3:5-dicyano- (V. MEYER and KLEINSTUCK), A., i, 910.

Diphenylmethylidithiocarbonate (BIILMANN), A., i, 143.

3-Diphenylmethylenediamine, di-m- and -p-bromo- (HOUBEN and ARNOLD), A., i, 534.

2:6-Diphenyl-4-methylenedioxypentylpyridine, 3-cyano- (V. MEYER and KLEINSTUCK), A., i, 912.

4:5-Diphenyl-1-methylglyoxalol-4:5-oxide. See 5:5-Diphenyl-3-methylhydantoin.

5:5-Diphenyl-3-methylhydantoin (4:5-diphenyl-1-methylglyoxalol-4:5-oxide) and its 1-formyl derivative (BLITZ, HORMANN, and RIMPPEL), A., i, 218; (BLITZ and RIMPPEL), A., i, 463.

Diphenylmethylolide, pentahydroxy-. See Glaucohydroellagic acid.

Diphenylmethylolidecarboxylic acid, pentahydroxy- (NIERNSTEIN), A., i, 897.

8-A-Diphenyl-a-methylpropionic acid, synthesis of, and its methyl ester and amide (EYKMAN), A., i, 795.

1:3-Diphenyl-2-methylpyrazole, 3-chloro-1-m-nitro- (MICHAELIS and WILBERT), A., i, 214.

1:3-Diphenyl-2-methyl-5-pyrazolone, 1-m-nitro-, and its nitrosoderivative (MICHAELIS and WILBERT), A., i, 216.

4:6-Diphenyl-2-methylpyridine and its 3-carboxylic acid and 3-cyano- (V. MEYER and IRMERSCHER), A., i, 911.

1:3-Diphenyl-2-methyl-5-thiopyrazolone and its 1-m-nitro-derivative (MICHAELIS and WILBERT), A., i, 215.

1:5-Diphenyl-2-methyl-3-thiopyrazolone and its derivatives (MICHAELIS and WILBERT), A., i, 214.

Diphenyl-4-oxamic acid, 4'-amino, 3-nitro-4'-amino, and 3-nitro-4'-amino-, and their N-acetyl derivatives (NEU-MOLLER), A., i, 369.

1:3-Diphenyl-3:3'-cyclopentadiene (BORSCH and MENZ), A., i, 150.

s-Diphenylpentamethylenediamine (s-diphenylpentamethylenediamine), synthesis of, and its mono- and di-cyano-, dinitroso-, and dibenzyl derivatives (V. BRAUN), A., i, 683.

1:3-Diphenylphthalan (NELKEN and SIMONIS), A., i, 348.

N-Diphenylpipеразине, di-m-nitro- (BORSCH and TITSCHING), A., i, 104.

2:6-Diphenylpiperezidine-3:5-dicarboxylic acid, ethyl ester, and its derivatives (PETRENKO-KRITSCHENKO and PETROFF), A., i, 565.

Diphenylpropane, di-p-hydroxy-, and its dibenzyl derivative and dimethyl ether (LUNJAK), A., i, 416.

aa-Diphenylpropionic acid, synthesis of (EYKMAN), A., i, 795.

ββ-Diphenylpropionic acid, synthesis of, and its amide and anilide (EYKMAN), A., i, 795.

β-hydroxy-, and its ethyl ester (RUPE and BUSOLT), A., i, 23.

Di-a-phenylpropylamine and its derivatives (BUSCH and LEEFHELM), A., i, 152, 153.

1:3-Diphenylpyrazole, 5-chloro-, and its 1-m-nitro-derivative (MICHAELIS and WILBERT), A., i, 215.

1:5-Diphenylpyrazole, 3-chloro-, and its derivatives (MICHAELIS and WILBERT), A., i, 213.

1:3-Diphenyl-5-pyrazolone and its 1-m-nitro-derivative (MICHAELIS and WILBERT), A., i, 215.

1:5-Diphenyl-3-pyrazolone and its derivatives (MICHAELIS and WILBERT), A., i, 213.

3:6-Diphenylpyridazine-4-carboxylic acid and its ethyl ester, synthesis of (PAAL and KÜHN), A., i, 57.

4:6-Diphenylpyridine-2:3-dicarboxylic acid (V. MEYER and IRMERSCHER), A., i, 911.

2:6-Diphenyl-4-pyrene and its platinichloride (RUHEMANN), T., 434; P., 52.

Diphenyl-γ-quinolylcarbinol and its salts (REMPHY and DECKER), A., i, 365.

Diphenylesemicarbazide (MICHAELIS), A., i, 471.

Diphenyl series, study of the diazo-reaction in the (MORGAN and MICKLETHWAIT), T., 614; P., 51.

Diphenylsulphone, 4:4'-diaminio-, and its diacetyl derivative, and 4:4'-dinitro- (FRÖMM and WITTMANN), A., i, 632.

Diphenylsulphonylhydroxylamine (HAGA), A., i, 870.

Diphenyl-2:3:5:6'-tetracarboxylic acid (BUCHER), A., i, 792.
INDEX OF SUBJECTS.

2:6-Diphenyltetrahydropyrone-3:5-di-carboxylic acid, ethyl ester, and its potassium salt (PETRENKO-KRIT-SCHENKO and DEMENTEYEV), A., i, 560.

Diphenyliothienylcarbinol (THOMAS), A., i, 360.

3:5-Diphenyltoluene-2:2':2''-tricarb-oxylic acid and its calcium salt and esters (ERKERA), A., i, 184.

Diphenyl-p-tolylacetyl chloride (BISTITZKY and LANDTWING), A., i, 270.

4:6-Diphenyl-2-p-tolylpyridine, 3-cyano- (v. MEYER and TRUMSCHER), A., i, 912.

1:5-Diphenyltriazole, 4-carboxylamide and 4-cyano- (v. MEYER AND SCHUMACHER), A., i, 912.

Diphenylurazine (ROLLA), A., i, 474.

αβ-Diphenylvaleric acid, 3-iodo-γ-hydroxy, lactone of (BOUGAULT), A., i, 538.

βγ-Diphenylvaleric acid, 3-amino, hydrochloride of (AVERY and MCDOLE), A., i, 796.

γγ-Diphenylvaleric acid, synthesis of (EYKMAN), A., i, 23.

Diphasthaminothylenalamic acid, ethyl ester, and the corresponding phthalamic acid, synthesis of (SORENSEN and ANDERSEN), A., i, 650.

Diphasthalaminothymenalamic acid, ethyl ester (SORENSEN and ANDERSEN), A., i, 651.

Diphtheria bacillus. See Bacillus. toxin, concentration of (HEINEMANN), A., ii, 770.

s-Dipiperidyldimethylcarbamide (EINHORN), A., i, 611.

o-Dipropylibenzene, di-a-hydroxy- (NELKEN and SIMONIS), A., i, 348.

p-Diosopropylbenzoquinone, hydrolis of (FICHTER and GLASER), A., i, 660.

d'hydroxy-, dibenzoate of (FICHTER and WEISS), A., i, 659.

Diosopropylformal, s-tetrachloro- (WOHL and ROTH), A., i, 942.

C-Dipropyl-glycollycyanamide and -glycollycarbamide and its salts (CLEMMENSEN and HEITMANN), A., i, 771.

Diosopropyquinoline and its picrate (VAN HOVE), A., i, 828.

5:5-Dipropylthiobarbituric acid (EINHORN), A., i, 315.

Dipyruvic-acid-n-phenylenedihydrazine (FRANZEN and EICHLER), A., i, 831.

Disaccharides, application of Barfoed's reagent to show the hydrolysis of, by enzymes (ROAF), A., i, 503.

Disalicylidenediacetone, cyclic oxonium salts from (DECKER and FELSER), A., i, 906.

Discharge. See under Electrochemistry.

Discharge potentials. See under Electrochemistry.

Diseases due to nerve degeneration, the chemical test for (BAUER), A., ii, 717.

infectious, changes in bile in some (BALDWIN), A., ii, 212.

Diselenides, preparation of (PRICE and JONES), P., 134.

Diselenodiglycollamides. See under Selenium.

Disinfecting powders and commercial carbolic acid (BLYTH), A., ii, 328.

Disinfection, laws of (CHICK), A., ii, 314.

variation in the rate of, with change in the concentration of the disinfectant (WATSON), A., ii, 976.

Dispersion. See under Photochemistry.

Dissociation. See under Affinity, chemical.

Dissociation processes in the sugar group (NEF), A., i, 5; (KILJANI), A., i, 128.

Dissociation spectra. See under Photochemistry.

Dissolved substances, internal energy of (SCHÜKARFF), A., ii, 462.

Distillation in high vacua, apparatus for (BÜLDER DE FLORIN), A., ii, 83.

apparatus for easily condensable gases and low-boiling liquids (V. BARTAL), A., ii, 929.

fractional, use of electrical heating in (RICHARDS and MATHEWS), A., ii, 828; (BECKMANN), A., ii, 1014.

under reduced pressure, apparatus for (DELEPINE), A., ii, 461; (STEINKOFF), A., ii, 663.

receiver for, under reduced pressure (VIGREUX), A., ii, 462.

steam, studies in (RICHMOND), A., i, 495, 754.

under reduced pressure (STEINKOFF), A., ii, 575.

vacuum, receiver for (KOLBE), A., ii, 575.

a simple manometer for (GEBHARD), P., 51.

vacuum fractional, receiver for (FREUNDLICH), A., ii, 829.
INDEX OF SUBJECTS.

ae-Distyryl-γ-diphenylmethylenediacetylene-Δαβ-
pentadiene (Staudinger), A., i, 412.

Disulphides, preparation of (Price and Twiss), T., 1395, 1401, 1645; P., 179, 185, 198.
isomerism of (Hinsberg), A., i, 257.
with neighbouring double linkings (Fromm, Baumeier, and Weller), A., i, 700.
organic, complex compounds of (Tschugaef), A., i, 615.

α-Disulphones, aromatic (Hilditch), T., 1524; P., 192.

Disulphoxides, preparation and constitution of (Hinsberg), A., i, 875.

Dithiocarbamic acid, barium salt (Andræsch), A., i, 684.

Dithiocarbamic acids, metallic derivatives of (Délepine), A., i, 511.

Dithiocaritateae acid and its ethyl ester (Billmann), A., i, 143.

β-Dithiocarimatepropionic acid (Billmann), A., i, 143.

Dithymol, preparation of, and the action of bromine on (Cousin and Hérisséy), A., i, 84, 162.
action of chlorine on (Cousin), A., i, 337.

Dithymoquinone, dibromo-(Cousin and Hérisséy), A., i, 162.

chloro-derivatives (Cousin), A., i, 337.

Di-o- and p-toluenesulphonimides (Haga), A., i, 871.

Di-p-toluidinoacetic acid and its ethyl ester (v. Ostromissensky), A., i, 389.

1:4-Di-o-toluidinoanthraquinone (Grandmougin), A., i, 809.

DitolyI anilinophosphates, o-, m-, and p- (Autenrieth and Geyer), A., i, 157.

Di-o-tolylarsinic acid, di-p-amino-, and its diacetyl derivative, and di-p-hydroxy (Benda), A., i, 747.

Ditolylibisazoacrosols (Schultz and Ichenhauers), A., i, 230.

Ditolylibisazonaphthalene and its sodium derivative (Schultze and Ichenhauers), A., i, 230.

Ditolylibisazonaphthol-6sulphonic acids, sodium salts, and their dibenzyl ethers (Schultz and Ichenhauers), A., i, 230.

Di-p-tolylcarbamide (Young and Duns- tan), T., 1058; P., 136.

p-Ditolyldihydrotolazine and dichloro- (Wieland), A., i, 1915.

Di-o- and p-tolydimethylmethylenediamines (v. Braun), A., i, 685.

Di-o-tolylmethylenpentamethylenediamine and its salts (v. Braun), A., i, 678.

Di-p-tolyl-a-disulphone (Hilditch), T., 1526; P., 192.

Ditolythelylenimide and its salts (Brünner and Rapin), A., i, 863.

Ditolyldinitrocarboxyhydradize (Stolle and Bowles), A., i, 474.

s-Di-p-tolymethylenediamine, 2,2'-dinitro- (Houben and Arnold), A., i, 534.

Ditolyloxalinochlorides, o-, m-, and p- (Bauer), A., i, 695.

β-Di-p-tolypipropionyl chloride (Bistrezycki and Landtving), A., i, 270.

Di-o-tolysulphophyldydroxylamine (Haga), A., i, 870.

Ditolyldioxide ferrichloride (Hoffmann and Ott), A., i, 84.

Diureines, behaviour of, towards acetic anhydride (Biltz and Horrmann), A., i, 62.

Diuresis (Biberfeld), A., ii, 972.
influence of calcium on (Porges and Pühram), A., ii, 718.

Dixanthyl derivatives, new (Silberrad and Roy), P., 205.

Dixanthyl-carbamide and thiocarbamide (Fosse), A., i, 41.

p-Dixyloquinone, dihydroxy-, hydrolysis of (Fichter and Kappler), A., i, 660.

Di-p-xylyl-a-disulphone (Hilditch), T., 1527; P., 192.

Docosyl alcohol and its urethane (Willstätter and Mayer), A., i, 383.

Dodecanolic acid. See asβγ-Tetramethyl-
Δ-octenolic acid.

Dog, fate of carbon acids in the (Fried- mann), A., ii, 205.

with Eck's fistula, experiments on a (Abderhalden and London), A., ii, 51; (Abderhalden and Olinger), A., ii, 961.

feeding and other experiments on (Hawk), A., ii, 305.
nuclein metabolism in a (Sweet and Levene), A., ii, 119.

alimentary canal of the. See Alimentary canal.

liver of the. See Liver.
suprarenal gland of the. See Supra-
renal gland.
excretion of cholesterol by the (Doré and Gardner), A., ii, 514.

Dogs, uremic, gaseous metabolism in (La Franca), A., ii, 303.

Dolomite, formation of (Philippi), A., ii, 302.
decomposition of (Knight), A., ii, 506.

Dossetin from the Japanese dyewood "Doss" (Ito), A., i, 441.
Drainage waters. See under Waters.
Drop weights, determination of physical constants by means of (Morgan and Stevenson), A., ii, 356; (Morgan and Higgins; Higgins), A., ii, 668.
Drugs, new (Einhorn, v. Diesbach, Feibelmann, and Ladisch), A., i, 312.
control and estimation of atomic complexes in (Lami), A., ii, 240.
action of, on the mammalian uterus (Fardon), A., ii, 1055.
Dulong and Petit's law (Wigand), A., ii, 13; (Rohland), A., ii, 459; (Richardz), A., ii, 562, 659.
Dung, estimation of potassium in (Schenke), A., ii, 321.
Duplobenzylideneacetophenone, thio-, α- and β- (Fromm and Lambrecht), A., i, 989.
Duplobenzylideneethioacetophenone (Fromm and Lambrecht), A., i, 990.
Duplodibenzylideneacetoneoxydi- and -tri-amines and -tri- and -penta-sulphides (Fromm and McKee), A., i, 991.
Duplobenzylidene-thioacetohydrazide, -oxythioacetohydrazide, and -heptaoxy- and hexaoxy-tetrasulphides (Fromm and McKee), A., i, 991.
Dust-figures, modification of Kündt's method of producing, by stationary waves (Behn and Geiger), A., ii, 99.
Dyeing, theory of (Fischer), A., ii, 759.
theory of, experimental examination of Gibbs's theory of surface-concentration, regarded as the basis of adsorption, with an application to the (Lewis), A., ii, 337.
explanation of (Pelet-Jolivet and Andersen), A., ii, 1026.
Dye bases, hydrosulphides and thiobenzylideneacetophenone, and -penta-sulphides of (Pelet-Jolivet and Grand), A., i, 226.
Dye salts, Wurster's constitution of (Willstätter and Piccard), A., i, 475; (Kehrmann), A., i, 699.
Dyes. See Colouring matters.
Dynamic isomerism. See under Affinity, chemical.
Dysprosium, ultra-violet spark spectrum of, and some remarkable magnetic properties of this element (Urbain), A., ii, 446.
Dysprosium chloride, oxide, nitrate, and sulphate (Urbain and Jantsch), A., ii, 189.

E.
Earth, rare (Erdmann and Wirth), A., ii, 694.

Earth, rare, anomalous magnetic rotation of the plane of polarisation of the (Elías), A., ii, 549.
dispersion of magnetic rotatory power in the neighbourhood of bands of absorption in (Bequerel), A., ii, 647.
absorption spectra of crystals of the, and the changes they undergo in a magnetic field at the temperatures of liquefaction and solidification of hydrogen (Bequerel and Onnes), A., ii, 338.
abnormal mobility of the ions of some (Roux), A., ii, 149.
scheme for the separation of the (James), A., ii, 498.
Earth, rare, bromates (James), A., ii, 190.
complex molybdates (Barbiert), A., ii, 595.
sulphides (Biltz), A., ii, 1037.
See also Cerium metals and Yttrium earths.
Earth-worm, chemical processes in the (Lesser), A., ii, 309.
enzymes in the (Lesser and Taschenberg), A., ii, 309.
Eberhardt's acid. See n-Nonadecamethylenedicarboxylic acid.
Eegonine, estimation of, in Java coca (de Jong), A., ii, 239.
Echinoderm eggs. See under Eggs.
Eclampsia, lactic acid in (ten Doeschate), A., ii, 122; (Donath), A., ii, 213.
Eel's serum, comparison of the hemolytic and toxic action of, on the marmot (Camus and Gley), A., ii, 215.
Egg-albumin, crystalline (Willcock), A., i, 485.
complete hydrolytic decomposition of, at 180° (Latham), A., i, 709.
influence of electrolytes on the coagulation temperature of (Ostwald), A., i, 375.
the production in vivo and in vitro of precipitins for, by means of antigens of a chemically definite nature (Mayer and Schäffer), A., ii, 868.
Eggs, cholesterol, pentose, and purines of (Mendel and Leavenworth), A., ii, 207.
echinoderm, oxidation processes in (Warburg), A., ii, 963.
Egg-shells, elementary analysis and distribution of nitrogen in various (Buchta), A., ii, 610.
Egg-shells of Scyllium stellare, the cleavage products of the (PREGL), A., ii, 609.

Egg-yolk, spectroscopic properties of (LEWIN, MIETHE, and STENGREN), A., ii, 1054.
a monoaminodiphosphatide in (MACLEAN), A., ii, 963.

the proteins of (PLIMMER), T., 1500; P., 190.
of Squalis acanthias, a globulin from (ALSBERG and CLARK), A., ii, 963.
d-tricycloEksantolol (SEMMLER), A., i, 434.

Elaomargaric acid, constitution of, and its anilide and esters (KAMETAKA), A., i, 850.

Elasticity, torsional, of liquids (LAUER and TAMMANN), A., ii, 667.

Electrochemistry:—

Electrochemistry of light (BANCROFT), A., ii, 448, 549, 788.
Accumulator, light (GOLDSCHMIDT), A., ii, 924.
iron-nickel peroxide, reactions in the (FOERSTER), A., ii, 558.

Jungner-Edison, nickel oxide electrode in the (ZEDNER), A., ii, 12.

Cells, cadmium chloride (v. BIRON), A., ii, 145.
alkal cadmium chloride (v. BIRON and APHANASSIEFF), A., ii, 249.
concentration (v. BIRON), A., ii, 145.

amalgam concentration, chemical, and Daniell, constructed with solid electrolytes (KATAYAMA), A., ii, 145.
iodine concentration, E.M.F. of, in water and alcohol (LARIE), A., ii, 1007.
with fused electrolytes, thermodynamics of (LORENZ and FOX), A., ii, 656.
galvanic, coagulation of colloidal solutions in (BILTZ), A., ii, 822.
hydrogen peroxide (BARNES and SHEARE), A., ii, 344.
liquid, thermodynamics of (HENDERSON), A., ii, 655.

with solid substances, thermodynamics of (LORENZ and KATAYAMA), A., ii, 249.
voltaic, of the Daniell type, new primary (STRACHAN), A., ii, 801.

Electricity, conduction of, by metals and amalgams (KINSKY), A., ii, 754.

Electrical conductivity, a peculiar type of (BADEKER and PAULI; BADEKER), A., ii, 654.

Electrochemistry:—

Electrical conductivity, diffusion constants, and viscosity, relation between (PISSARJEWSKY and KARP), A., ii, 566.
and ionisation of acids, bases, and salts in aqueous solutions at high temperatures (NOYES, MICHELE, COOPER, EASTMAN, and KATO), A., ii, 347.
and temperature, relation between (RASCH and HINRICHSEN), A., ii, 149.
and viscosity (ARNDT), A., ii, 87; (LEMCKE), A., ii, 251.
and viscosity of aqueous solutions (GREEN), T., 2023, 2049; P., 187.
and viscosity of solutions of certain salts in water, methyl alcohol, ethyl alcohol, acetone, and in binary mixtures of these solvents (JONES and VEAZLEY), A., ii, 259, 260.
in mixtures of acid or base and water (BOIZARD), A., ii, 251, 346.
in systems containing zine sulphate, ammonia, and water (SHUMAKOFF), A., ii, 457.
of alloys and their temperature coefficients (GURTLER), A., ii, 557; (RUDOLF), A., ii, 923.
of gaseous mixtures at the moment of explosion (DE MUYNCK), A., ii, 345.
of fused salts (ARNDT and GESSLER), A., ii, 923.

Electric arc between metal electrodes (Cady and Arnold), A., ii, 10.
difference of potential in the, produced by a continuous current between metallic electrodes (GUYE and ZEBRIKOFF), A., ii, 150.
alternating, stability of the, and difference of potential between metals (GUYE and BRON), A., ii, 561.

stability of the; a function of the atomic weight of the metallic electrodes (GUYE and BRON), A., ii, 755.

high tension, experimental investigation of the (BRON), A., ii, 10.

Electric conductor, incandescent, action of an, on the surrounding gas (COUILOT and MEVIER), A., ii, 11.

Electric currents, alternating, electrolytic rectification of (SCHULZE), A., ii, 658.

Current passivity, alternating, signification of so-called (LÖN), A., ii, 13.
Electrochemistry:—

Current-potential curve, influence of the velocity of ionic reactions on the (Eucken), A., ii, 1008.

Arc discharge, products of, in liquid argon (Fischer and Iliovici), A., ii, 1034.

Arc light, action of, on gases (v. Traubenberg), A., ii, 1012.

Electric discharge, is the fixation of atmospheric nitrogen in the, to be regarded as a purely thermal effect? (Brion), A., ii, 561.

from a glowing lime cathode in mercury vapour, spectrum of the (Horton), A., ii, 745.

in monatomic gases (Soddy and Mackenzie), A., ii, 151.

explosive, invisible radiations from the (Schinzaglia), A., ii, 796.

silent, influence of, on explosive gaseous mixtures (Fassbender), A., ii, 561.

does the law of the action of mass hold for the? (Le Blanc and Davies), A., ii, 653; (Pohl; Le Blanc), A., ii, 819.

Point discharge through hydrogen containing oxygen and nitrogen, changes of pressure which accompany (Chattock and Tyndall), A., ii, 652.

Spark discharge, action of, on gases (v. Traubenberg), A., ii, 1012.

products of, in liquid argon (Fischer and Iliovici), A., ii, 1034.

Electric osmosis (Frazer and Holmes), A., ii, 1019.

Electrical resistance and expansion of metals, relation between the (Broniewski), A., ii, 147.

Electrotransport of inorganic colloids (Mayer and Salles), A., ii, 458.

Glow, stratified positive, experimental investigation of the (Holm), A., ii, 796.

Electrification, laws of contact, and Bose's phenomenon (Guillaume), A., ii, 753; (Perrin), A., ii, 754.

Equilibrium between metals and solutions of metallic salts (Bose), A., ii, 569.

\[2\text{Au} \cdot \text{metal} + \text{Au} \cdot \text{argon} \rightarrow 3\text{Au} \cdot \text{argon} \] (Bose), A., ii, 264.

Electrocapiillary measurements by the method of large drops (Gouy), A., ii, 654.

Electrochemical adsorption and binary electrodes (Michaelis), A., ii, 655.

Electrochemistry:—

Electrochemical equivalent and temperature (Kohlrausch and Weber), A., ii, 82.

equivalents, use of the micro-balance for the determination of (Brill and Evans), T., 1442; P., 185.

Electro-optical properties of liquid mixtures (Chaudier), A., ii, 788.

Dielectric constant and chemical constitution, relation between (Stewart), T., 1059; P., 124.

and solvent power (Walden), A., ii, 159.

and ionising power of solvents, relation between the (McCoy), A., ii, 657.

of gases at high pressures (Tangl), A., ii, 559.

apparatus for determining the, of organic liquids (Stewart), T., 1062; P., 124.

Super-tension, explanation of (Kaufler), A., ii, 558, 1008; (Muller), A., ii, 802.

Anions, mobilities of isomeric (Le and Ehrler), A., ii, 21.

Anodes, electrolytic, classification of the behaviour of (Schulze), A., ii, 350.

Anodic polarisation, anomalous, by nitric acid (Schellhaass), A., ii, 249.

Cathode, Wehnelt, in high vacua (Soddy) A., ii, 81; (Wehnelt), A., ii, 147; (Lilienfeld), A., ii, 248.

Cathode potential fall in some compound gases (Gehlhoff), A., ii, 11.

Cathodic volatilisation in attenuated gases (Kohlschutter and Goldschmidt), A., ii, 457; (Fischer and Hahn), A., ii, 553, 800, 925; (Kohlschutter), A., ii, 799, 900, 925; (Walter), A., ii, 925.

Electrodes, electrolytic depositions on inclined (Goldschmidt), A., ii, 536.

alkali (Muller and Allemandet), A., ii, 146.

binary, and electrochemical adsorption (Michaelis), A., ii, 655.

bromine or chlorine, for use at high temperatures (Lorenz and Fox), A., ii, 656.

behaviour of calcium and sodium amalgams as, in solutions of neutral salts (Byers), A., ii, 926.
INDEX OF SUBJECTS.

1315

Electrochemistry:

Electrodes, hydrogen, potential of, in acid and alkaline solutions (Schmidt and Finger), A., ii, 802.

Electrolytes, conductivity and ionisation of, in aqueous solutions, as conditioned by temperature, dilution, and hydrolysis (Jones and Jacobsen), A., ii, 1011.

Electrolyte, calculation of the dissociation of an (Lewis), A., ii, 657.

Electrolytic analysis. See under Analysis.

Electrolytic chlorination. See Chlorination.

Electrolytic conduction, examination of the conception of hydrogen ions in (Lapworth), T., 2187; P., 275.

Electrolytic conductivity of weak electrolytes with negative heat of dissociation, effect of concentration on the temperature of maximum (Wegelius), A., ii, 801.

Electrolytic decomposition of dicyanamyl organic acids (Vanzetti), A., i, 939.

Electrolytic depositions on inclined electrodes (Goldschmidt), A., ii, 536.

Electrolytic dissociation of the polyiodides of the alkali metals and ammonium radicles (Dawson and Jackson), P., 2063; P., 213.

Electrolytic preparation of alkali chlorates and perchlorates (Couleru), A., ii, 659.

Electro-syntheses (Losantshch), A., i, 846, 866; ii, 32.

Electromotive force of iodine concentration cells in water and alcohol (Laure), A., ii, 1007.

Electromotive forces, thermodynamic calculation of (Halla), A., ii, 755.

Photo-electric sensitiveness and fluorescence of organic substances (Stark and Steubing), A., ii, 746.

Electron, the, as an element (Ramsay), T., 774; P., 87.

Electrons, emission of, by heated metallic oxides (Jentzsch), A., ii, 652.

Electron theory and optical properties (Erkle), A., ii, 77.

and valency (Stark), A., ii, 138; (Kauffmann), A., ii, 478.

Ionisation, part played by, in certain chemical reactions (Oechsner de Conick), A., ii, 804.

and conductivity of acids, bases, and salts in aqueous solutions at high temperatures (Noyes, Melcher, Cooper, Eastman, and Kato), A., ii, 947.
Electrochemistry:—

Ionisation and conductivity of electrolytes in aqueous solutions as conditioned by temperature, dilution, and hydrolysis (Jones and Jacobson), A., ii, 1011.

of gases by α-rays, and the hypothesis of initial recombination of the ions (Moulin), A., ii, 921.

of liquid dielectric media by radium rays (Jaffe), A., ii, 148.

secondary, quality of, due to β-rays (Bracc and Madsen), A., ii, 921.

Ionisation constants, secondary, of dibasic acids, determination of the (McCoy), A., ii, 466; (Chandler), A., ii, 467; (Wegscheider), A., ii, 1009.

Ionisation phenomena, influence of pressure on, produced in gases by X-rays (Rothé), A., ii, 1007.

produced by snow (Costanzo and Negro), A., ii, 551.

Ionic concentrations, calculation of, from measurements of potential in concentration cells (Lewis), A., ii, 657.

Ionic experiments on metals in liquid ammonia (Kraus), A., ii, 835.

Ionic mobility, elucidation of the connexion between, and the fluidity of the solution (Green), T., 2049; P., 187.

and temperature coefficient, relation between (Lasch and Hinrichsen), A., ii, 148.

abnormal, of some rare earths (Roux), A., ii, 149.

Ionic mobilities in water, temperature-coefficients of, as a function of the mobilities (Kohlrausch), A., ii, 264.

Ionic reactions, influence of the velocity of, on the current-potential curve (Eucken), A., ii, 1008.

Ionic volume and viscosity (Getman), A., ii, 931.

Ionising power and dielectric power of solvents, relation between the (McCoy), A., ii, 657.

Ionising solvent, antimony trichloride as (Klemensiewicz), A., ii, 1048.

Ions, genesis of, by collision of positive and negative ions in a gas (Gill and Pidduck), A., ii, 798.

emitted by hot substances, specific charge of (Richardson), A., ii, 1009.

experiments to ascertain the molecular complexity of (Chattock and Tyndall), A., ii, 652.

Electrochemistry:—

Ions, determination of the hydration of, by transference, in presence of a non-electrolyte (Washburn), A., ii, 1009.

determination of the hydration of, from measurements of electromotive forces (Lewis), A., ii, 805.

migration of, in heterogeneous systems (Spiero and Henderson), A., ii, 804.

gaseous, diffusion of (Salles), A., ii, 931.

metallic, action of, on the frog's heart (Gautret), A., ii, 120.

negative, emission of, by heated metals and by heated calcium oxide (Deininger), A., ii, 83.

Potential of a hydrogen electrode in acid and alkaline solutions (Schmidt and Finger), A., ii, 802.

Potentials, discharge, of the ions in solutions of alkali alkylxides (Carrara and Bringhenti), A., ii, 755.

Potential differences at the contact of two electrolytes; Nernst's theory (Guyot), A., ii, 856.

contact, determined by means of null solutions (Smith and Moss) A., ii, 343.

and the stability of the alternating arc between metals (Guye and Bron), A., ii, 561.

Potential series, aluminium in the (van Deventer and van Lummel), A., ii, 12, 555; (van Laak), A., ii, 248, 558.

Transference numbers, improved apparatus for the measurement of, in solutions of the halogen acids and their salts (Washburn), A., ii, 805.

Voltmeter, a lecture (Pitoni), A., ii, 657.

copper, anomalous behaviour of the (Meyer), A., ii, 803.

electrolytic gas (Lehfeldt), A., ii, 559.

Micro-voltmeter, silver (Bose and Conrat), A., ii, 250.

Element, new conception of the (Mieri), A., ii, 478.

supposed formation of new (Jovitschitsch), A., i, 118.

Elements, new, in thoriumite (Evans), T., 666; P., 60; (Ogawa), A., ii, 952, 953.

evolution and devolution of the (A. C. and A. E. Jessup), A., ii, 96.

atomic weights of the (Wilde), A., ii, 1027.
Elements, certain relations between the atomic weights of the (DeLanay), A., ii, 97.
periodicity, weight, and valency of the (Woodiwiss), A., ii, 368.
and compounds, wave-length tables of the spectra of the (British Association Reports), A., ii, 334.
potential energy of the (Rankin), A., ii, 630.
specific heat of the, between the temperature of liquid air and room temperature (Nordmeyer), A., ii, 333.
energy of the (Bekkoff), A., ii, 478.
action of iodine on some, in vacuum (Guichard), A., ii, 31.
solid, specific heat of, and Dulong and Petit's law (Wigand), A., ii, 13; (Rohland), A., ii, 459; (Richards), A., ii, 562, 659.
non-metallic, valency and specific gravity of (Woodiwiss), A., ii, 564.
See also Metalloids.
phosphorescent, and meta-elements of Sir W. Crookes, nature of the (Urbain), A., ii, 108.
Elemicin and isoelemicin, constitution of (Semmler), A., i, 553, 664.
from elemi oil (Semmler), A., i, 557.
Ellagic acid, preparation and constitution of (Hitzig, Polak, and V. Bronneck), A., i, 546.
Emission spectra. See under Photochemistry.
Emodin (trihydroxy-2-methyl-9:10-anthraquinone) from Frangula from aloes, trimethyl ethers of (Oesterle and Tasza), A., i, 350.
Emodins, constitution of the (Oesterle and Tasza), A., i, 905.
Emodinantheranol (Hesse), A., i, 439.
Emphlein from the kinos of the Eucalyptus (Smith), A., ii, 886.
Emulsin, hydrolysis of amygdalin by (Auld), T., 1251, 1276; P., 97, 181; (Rosenthaler), A., i, 197, 817; (Feist), A., i, 437, 903.
Enzymes of (H. E. and E. F. Armstrong and Horton), A., i, 745.
Enargite from Servia (Stevanovic), A., ii, 306.
4.5 Endoxy-2-oxy-4.5-diphenyl-1-methyl- and 1:3-dimethyl-tetrahydroglyoxalines. See 4.5-Diphenyl-1-methyl- and 1:3-dimethyl-glyoxalines.
Endoxypyrrodiazoles. See 4.5-Oxy-1:2:5-o-methylendoxypyrrodiazoles.
Energy. See under Affinity, chemical.
Eno-abura. See Perilla, oil of.

Enolic and ketonic compounds, behaviour of, with diazo-compounds (Tingle and Williams), A., i, 126.
 tertiary amines as reagents for distinguishing between (Michael and Smith), A., i, 943.
the ammonia reaction for distinguishing between (Michael and Hibbert), A., i, 78.
 acetyl chloride and acetic anhydride as reagents for distinguishing between (Michael and Murphy), A., i, 949.
Enstatite-augite in diabase from Tasmania (Osann), A., ii, 48.
Entropy, the law of, and stereoisomerism (Michael), A., ii, 137.
variation of, in monovariant systems (Matignon), A., ii, 465.
Enzymatic processes, action of poisons on (Santesson), A., ii, 1061.
Enzyme, alcoholic, of yeast-juice (Harden and Young), A., i, 590.
hydrolytic, in the resting seeds of some Gramineae (Tanaka), A., i, 489.
Enzyme action. See under Affinity, chemical.
Enzymes, studies on (Sorensen), A., i, 115; (Sorensen and Jessen-Hansen), A., ii, 234.
and antiferments (Jacoby), A., i, 236; ii, 743.
of the earth-worm (Lesser and Taschenberg), A., ii, 309.
of emulsin (H. E. and E. F. Armstrong and Horton), A., i, 745.
of gastric and pancreatic juices, action of, on vegetable proteins (Stutzer and Mires), A., ii, 404.
of nuclein metabolism (Schittenhelm), A., ii, 960.
adsorption of (Michaelis and Ehrenreich), A., i, 587; (Michaelis), A., i, 745.
influence of colloids on (Pincussohn), A., ii, 398.
catalytic reactions induced by (Arcey), A., ii, 1022.
catalytic and hydrolytic, acting during the ripening of fruit (Tallarico), A., ii, 724.
action in the dark of fluorescent substances on, and its reversibility (Kudo and Jodlbauer), A., ii, 867.
de-amidising, of fungi (Pringsheim), A., ii, 773.
diastatic, action of manganese and iron sulphates on (Gigon and Rosenberg), A., ii, 870.
Enzymes, diastatic, new method for estimating (Wohlgemuth), A., ii, 444.

digestive, influence of certain food adjuncts on the action of (Togami),
A., ii, 513.
nitrate-reducing, in green plants (Irving and Hankinson), A., ii, 218.
oxidising, amount of nitrogen in (Bach), A., ii, 238.
peptic and trypptic, colorimetric method applicable to both (Roaf),
A., ii, 743.
peptolytic, in germinating and un-germinated seeds of various plants
(Abderhalden and Dammhahn), A., ii, 1065.
in the stomach contents (Abderhalden and Medigeceanu),
A., ii, 1049.
reducing, are there, in the animal body? (Heffter), A., ii, 1054.
See also Co-enzyme.

Enzymes. See also:—

Amidase.
Amylase.
Catalase.
Chymosin.
Diastase.
Emulsin.
Erepsin.
Glyoxylase.
Hydrogenase.
Invertase.
Laccase.
Leucoprotease.
Lipase.
Maltase.
Oxydases.
Pepsin.
Peroxydases.
Phaseolunatase.
Philothion.
Phytase.
Protein-ferment.
Pyralin.
Reductase.
Rennet.
Rennin.
Tryptase.
Tryptase.
Tyrosinase.
Zymase.

Ephedrine and \( \psi \)-Ephedrine, (Schmidt),
A., i, 452.
a case of asymmetry due to dissimilar halves (Emde), A., i, 203.

Epichlorohydrin, condensation of, with phenols (Boyd and Marle), T.,
388; P., 92.
\( \psi \)-cyanate, derivatives of (Paternò and Cingolani), A., i, 308.

Epinephrine. See Adrenaline.

Equation of condition for metals: a correction (Grünewein), A., ii, 563;
(Thiesen), A., ii, 659, 808.

Equilibrium:—

Phase rule, Gibbs', deduction of (Muller), A., ii, 466.
Equilibrium of two substances in a mixed binary solvent (Volchonsky), A., ii, 934.
in ternary systems (Mascarelli), A., ii, 94, 162.
in quaternary systems (Schreinemakers), A., ii, 571, 935.
the system, water, and sodium, barium, and copper chlorides
(Schreinemakers and de Baat), A., ii, 1020.

Phases, influence of slow dissociation on the equilibrium between (van Rossem), A., ii, 361.

Equilibrium, chemical. See under Affinity, chemical.

Erbum salts, variations of the absorption bands of, in a magnetic field (Becquerel), A., ii, 78.

Erbum and holmium, separation of (Hofmann and Burger), A., ii, 189.

Erepsin (Raubitscheck), A., ii, 517.

Ergosterol and its esters (Tanret), A., i, 637.

Ergosterol esters, liquid crystals of (Gaubert), A., i, 882.

Ergot, constituents of (Kraft), A., i, 203; (Barger and Dale), A., i, 204.

Ergotoxine (hydroergotin) (Barger and Dale), A., i, 204.
sulphate, crystalline (Kraft), A., i, 203.

Eucaly alcohol and its dibromide (Willstatter and Mayer), A., i, 383.

Erytaria from the common century (Hérissey and Bourdier), A., i, 903.

\( \tau \)-Erythric acid, synthesis of, and its hydrazide and brucine salt (Lespieau),
A., i, 4.

dl-Erythric acid and its phenylhydrazide (Nef), A., i, 7.

Erythrit (Wallach), A., i, 432.

\( \psi \)-Erythritol, synthesis of (Lespieau)
A., i, 4.

\( \alpha \)-Erythroderxin (Tanaka), A., i, 490.
dl-Erythrolactone and its dibenzoyl derivative (Nef), A., i, 7.

Erythronic acid. See Erythric acid.

Erythrosin silver, blue (Lüppo-Cramer),
A., i, 669.

"Erythrosine," estimation of organically-combined chlorine and iodine in
(Jean), A., ii, 129.
Eserine (physostigmine), action of, on nerve-endings (EDMUND and ROTH), A., ii, 966.

Ester, C_2H_4O_2P, from the sodium derivative of methyl methycyclopentan-4-one-3-carboxylate and ethyl bromoacetate (BLANC), A., i, 20.

Ester anhydrides, simple, of saturated dibasic acids (MOI.), A., i, 76.

Ester catalysis (FITZGERALD and LAPWORTH), T., 2163; P., 274.

Ester hydrolysis (LAPWORTH), P., 152.

Esterification, theories of (LAPWORTH), P., 152; (STIEGLITZ; ACREE), A., ii, 472.

Estragole derivatives (DAUFRESNE), A., i, 19.

Ethane, thermal decomposition of (BONE and COWARD), T., 1197; P., 167.

Ethanodicarboxylic acid. See Methylmalonic acid and Succinic acid.

Ethanolamines, aromatic, preparation of (FAHRWERKE VOM. MEISTER, LUCIUS, & BRÜNING), A., i, 418.

Ethenylamino-oxime, bromo-derivatives (STEINKOPF and GRÜNUPP), A., i, 966.

Ether. See Ethyl ether.

Ether acids, washing of alkyl groups during the distillation of (POLLAK and FELDSCHAREK), A., i, 542.

Ethers, formation of, from compounds of the benzoin type (IRVINE and MCNICOLL), T., 1601; P., 191.

Ethyl alcohol, new method of preparing some simple (VAN HOVE), A., i, 827.

Ethylenediamine, aromatic or fatty primary, general method for the preparation of (Hamonet), A., i, 242; (REYCHLER), A., i, 383.

Ethylenedinitrobenzene, aromatic, reduction of, in presence of nickel oxide (IPATIEFF and PHILIPOFF), A., i, 342.

Ethylene-Dichloride, mixed alkyl aromatic, preparation of (FAHRENFAHRKEN VOM. F. BAYER & CO.), A., i, 263.

Ethylenedinitrobenzene, of the higher alcohols, preparation of (SCHROETER and SONDAG), A., i, 497.

See also Acetals.

Ethotolusafarane hydrochloride (FAHRWERKE VOM. MEISTER, LUCIUS, & BRÜNING), A., i, 225.

Ethylene, lead, formation of (PERKIN), P., 179.

Ethoxyacetylphosphonic acid, dibromooethyl ester (STEINKOPF and GRÜNUPP), A., i, 962.

3-Ethoxyaniline, 2,6-dinitro- (BLANKSMA), A., i, 158.

Ethoxybenzene. See Phenetole.

P-Ethoxybenzenesalicylic acid and its acetyl derivative (GRANDMOUGIN and GUIBAX), A., i, 927.
INDEX OF SUBJECTS.

p-Ethoxybenzoic acid, m-amino, urethane of (AKTIEN-GESellschaft für ANILIN-FABRIKATION), A., i, 339.
β-bromo- (GATTERMANN), A., i, 32.

p-Ethoxybenzylideneamino-α-alkylcinnamic acids, esters, and their liquid crystals (VÖRLANDER and KASTEN), A., i, 641.

β-Ethoxybutane, α-chloro- (ethylene glycol-chlorhydrin ether) (HOUVEN and FÜHRER), A., i, 73.
β-Ethoxycrotonic acid, γ-chloro-α-cyano-, ethyl ester (BENARY), A., i, 600.

4-Ethoxy-2:6- and 3:5-dimethylbenzaldehydes (GATTERMANN), A., i, 33.

Ethoxydicyclopentadiene, compound of, with platinous chloride (HOFFMANN and v. NARBURT), A., i, 520.

3-Ethoxydiphenylamine, 2:6-dinitro-(BLANKSMA), A., i, 158.
α-Ethoxyethylbenzene, β-chloro- (HOUVEN and FÜHRER), A., i, 74.
1 a-Ethoxyethylnapthalene, β-chloro- (HOUVEN and FÜHRER), A., i, 74.

Ethoxyethyltheophylline (SCHWABE), A., i, 45.

6-Ethoxy-2-ethylthiol-4-methylpyrimidine (JOHNS), A., i, 917.
6-Ethoxy-2-ethylthiopyrimidine-5-carboxylamide (WHEELER and JOHNS), A., i, 839.

β-Ethoxyisohexitane, iso-α-chloro- (HOUVEN and FÜHRER), A., i, 74.

β-Ethoxyisohexane, α-chloro- (HOUVEN and FÜHRER), A., i, 73.

2-Ethoxyindene, 3-cyano-, formation of (MOORE and THORPE), T., 177; P., 13.

3-Ethoxymethylaniline, 2:6-dinitro-(BLANKSMA), A., i, 158.

p-Ethoxy-β-methylcinnamic acid (SCHROETER and BUCHHOLZ), A., i, 170.

Ethoxymethylcyclohexene (ZELINSKY and GORSKY), A., i, 620.

5-Ethoxy-1-methylindole sodium sulphite (HINSBERG), A., i, 453.

5-Ethoxy-1-methyloxindole and its nitrosamine (HINSBERG), A., i, 453.

Ethoxy-1-naphthaldehyde, 2- and 4-, and their azines (GATTERMANN), A., i, 33.

p-Ethoxyphenylacetonitrile (V. MEYER and SCHUMACHER), A., i, 910.

5-Ethoxy-1-phenyl-3-methylpyrazole, 4-amino-, and its hydrochloride and acyl derivatives (FAHRWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 472.

6-Ethoxy-2-phenylpyrimidine, 4-hydroxy- (PINNER), A., i, 1018.

Ethoxyphenyl-. See also Phenetyl-.

α-Ethoxypropionbenzene, γ-chloro- (HOUVEN and FÜHRER), A., i, 74.

α-Ethoxystryrene (TIPPENHAUS), A., i, 19.

9-Ethoxy-A(-)-tetrahydrocarbazole (BORSCHE, WITTE, and BOTHE), A., i, 366.

Ethoxytolualdehydes and their derivatives, synthesis of (GATTERMANN), A., i, 32.

1-Ethoxy-1:2:3-triphenylindene (KOHLER), A., i, 777.

o-Ethoxytritanol-6-sulphonic anhydride (V. LIBIG and HERB), A., i, 450.

Ethyl alcohol, preparation of, from substances containing cellulose (KOERNER), A., i, 855.

absolute, preparation of, and refractive indices of mixtures of, with water (ANDREWS), A., ii, 333.

and water, index of refraction of mixtures of (DOROSCHEWSKY and DVORSCHANTSCHIK), A., ii, 241; (ANDREWS), A., ii, 333.

electrical conductivity of mixtures of, with water (DOROSCHEWSKY and ROSCHDESTVENSKY), A., ii, 800.

and its mixtures with water, specific heat of (DOROSCHEWSKY and RAKOWSKY), A., ii, 807.

changes of specific heat of, dissolved in liquid hydrocarbons (SHEEDER), A., ii, 460.

viscosity of (GAILLARD), A., i, 73.

Tables for converting percentages of, by volume into percentages by weight (BLONDEAU), A., ii, 738.

oxidation of, by a contact process (ORLOFF), A., i, 306.

and water, composition of the vapour from mixtures of (MASING), A., i, 751.

action of, on the heat relationships of the animal organisms (HARNACK and LABLE), A., ii, 404.

effect of, on digestion (ZITOWITSCHE), A., ii, 404.

tolerance to (PRINGSHEIM), A., ii, 767.

detection and estimation of small quantities of benzene in (HOLDE and WINTERFELD), A., ii, 495.

indirect estimation of, by refraction (FRANK), A., ii, 637.

estimation of, in concentrated ethyl nitrite (PEARSON), A., ii, 436.
INDEX OF SUBJECTS. 1321

and extract, estimation of, in spirits by the refractometer (Race), A., ii, 738.
estimation of, in wine (Duboux and Dutoit), A., ii, 136.
Ethyl alcohol, d'i'luoro-, preparation of (Swarts), A., i, 752.
Ethyl cuprocyanide (Guillemand), A., i, 720.
cyanide, preparation of (Auger), A., i, 81.
Ethyl ether, measurement of the ratio of the two specific heats of, with the help of Kundt's dust figures (Döring), A., ii, 153.
action of bromine on (Mauguin), A., i, 941.
contact oxidation of (Orloff), A., i, 753.
anesthesia, effect of, on nitrogen excretion (Hawk), A., ii, 410.
phosphite-platochloride, compound formed by the addition of ammonia to (He and Davis), A., i, 598.
ortosilicate, action of Grignard reagents on (Kotinsky and Seregenkoff), A., i, 1032.
sodium thiosulphate, action of alkalis on (Gutmann), A., i, 497.
Ethylamine, catalytic action of (Brunner and Rapin), A., i, 863.
action of, on isatin (Haslinger), A., i, 454.
action of n-propyl chloride on (Comanducci and Arena), A., i, 138.
γ-Ethylaminoacetacetic acid, α-cyano-, ethyl ester and its salts (Benary), A., i, 601.
Ethylaminobenzaldehydephenylhydrzone, liquid crystals of (Rotarski), A., i, 640.
Ethylaniline picate (Vignon and Évieux), A., ii, 665.
Ethylaniolpyrines, 2- and ψ-, and their derivatives (Michaelis and Mielecke), A., i, 61.
δ-Ethylbarbituric acid, preparation of (Boehringer and Söhne), A., i, 464.
electrolytic reduction of (Tafel and Thompson), A., i, 58.
m-Ethylbenzaldehyde, p-hydroxy-, and its azine, synthesis of (Gattermann), A., i, 28.
Ethylbenzyldiamine and its hydrochloride and nitrate (Busch and Lefhelm), A., i, 153.

Ethylcyclobutane (Zelinsky and Gutt), A., i, 617.
a-Ethylbutyric acid, γ-chloro-α-hydroxy-, ethyl ester, and its acid αγ-oxide (Maire), A., i, 248.
γ-Ethylbutyro lactone-γ-carboxylic acid and its ethyl ester (Maire), A., i, 248.
a-Ethylbutyryldiethylglycynamethylene diamine (Einhorn), A., i, 610.
Ethylcattle, dichloro-, cyclic carbonates of (Barger), T., 2051 ; P., 237.
a-Ethylcrotonamide and its dibromido (Mannich and Zernik), A., i, 399.
Ethyl β-diethylaminoethyl ketone and its semicarbazone and picrate and its reduction (Blaise and Maire), A., i, 398.
Ethylidy-n-propylamine and its additive salts (Comanducci and Arena), A., i, 139.
Ethylene, thermal decomposition of (Bone and Coward), T., 1197 ; P., 167.
condensation product from, by means of the dark electric discharge (Jovitschitsch), A., i, 118.
condensation products, absorption of oxygen by (Losantitsch), A., i, 846.
derivatives, methylation in, from the point of view of volatility (Henry), A., i, 752.
Ethylene, tri bromo- and trichloro-, mercuric derivatives of (Hofmann and Kirrreuther), A., i, 145.
tetraiodo-, crystal form of (Jaeger), T., 523 ; P., 29.
Ethylene glycol, colour of (Spring), A., i, 118.
compounds of, with metallic salts (Grün and Bockisch), A., i, 934.
ether of, pressure and composition of the vapours of aqueous solutions of (Makovetzki), A., i, 753.
Ethylene glycol-chlorohydrin ether. See β-Ethoxybutane, a-chloro-
Ethylene oxides, action of magnesium organic compounds on (Fourneau and Tiffeneau), A., i, 163.
Ethylene-blue. See Tetraethylthionine.
amino-, bromo-, and nitro-, and their salts (Gnehm and Schindler), A., i, 111.
Ethylendiamine cobalt thiocyanate, action of iodine on (Pfeiffer and Tilgner), A., i, 614.
compounds of, with chromium salts (Pfeiffer), A., i, 79 ; (Pfeiffer, Prade, and Stern), A., i, 506 ;
(Pfeiffer, Vorster, and Stern), A., i, 507.

XCIV. ii.
Ethylendiamine, compounds of, with chromium and cobalt salts (Pfeiffer, Gassmann, and Pietsch), A, i, 508.
Ethylendicarboxylic acids. See Fumaric acid and Maleic acid.
Ethylendiguanide and its additive salts (Dittler), A, i, 924.
Ethylene-green. See Ethylene-blue, nitro-
Ethylene-sulphur, tetraiodo- (Auger), A, i, 241.
Ethylglycollic acid, glucinum salt (Glasmann and Novicky), A, i, 121.
Ethyl groups, twin, pharmacological significance of (Frankel), A, ii, 1060.
Ethyl-A\textsuperscript{1}-cyclohexene and its nitrosochloride and nitrotpiperidine (Wallach and Mendelssohn-Bartoldy), A, i, 404.
1-Ethyl-A\textsuperscript{1}-cyclohexen-3-one and its oxime and semicarbazone, and 4-carboxylic acid, ethyl ester, and its semicarbazone (Blaise and Maire), A, i, 391.
N-Ethylhomopapaverinum derivatives (Decker and Dunant), A, i, 206.
Ethylhydrantocid (Bailey and Randolph), A, i, 741.
5-Ethylhydrouracil (Tafel and Thompson), A, i, 58.
Ethyl hydroxytet-butyl ketone and its acetyl derivative (Blaise and Herman), A, i, 248.
Ethylidenecetoacetic acid, ethyl ester, semicarbazide-semicarbazone of (Rupe and Hinterlach), A, i, 13.
Ethylideneacetic acid, action of organomagnesium haloids on (Gry), A, i, 307.
Ethylidenecetonesemicarbazide-semicarbazone (Rupe and Hinterlach), A, i, 13.
Ethylidene-o-aminobenzoic acid, trichloro-. See Chloralanthranilic acid.
Ethylidenedi-o- and -p-methoxyphenylamines, trichloro-, and their bromo-compounds (Wheeler and Dickson), A, i, 333.
Ethylidenedi-o-tolylamine, trichloro-, and its bromo-derivative (Wheeler and Jordan), A, i, 333.
Ethylidenedinrethane, tribromo- (Diels and Ochs), A, i, 10.
Ethylidene(cyclo)hexane. See cycloHexene-cethane.
\textit{i}-Ethylidenelactic acid. See Lactic acid.
Ethylidene phosphamic acid, chloro-bromo-compounds, derivatives of (Steinkopf, Grünupp, and Kirchhoff), A, i, 962.
Ethyliminocycloheptane-carboxylic acid, cyano-, ethyl ester, hydrochloride of (Stadnikoff), A, i, 266.
3-Ethyliminocetatin and its reactions (Haslinger), A, i, 454.
Ethyl ketones, \(\beta\)-chloro-, reactions of (Maire), A, i, 247; (Blaise and Maire), A, i, 390.
action of nitrogen-containing reagents on the carbonyl group of (Maire), A, i, 290.
Ethylmalonylureide, ethyl ester (Boehringer & Söhne), A, i, 464.
\(\alpha\)-Ethylmeconine, amino-, and its additive salts, bromo-, and nitro- (Mermot and Simonis), A, i, 343.
Ethylcaphthalenes, \(\alpha\)- and \(\beta\), preparation of (Darzens and Rost), A, i, 411.
1-Ethynipeticoinic acid (1-ethyipiperidine-3-carboxylic acid (Wohl and Losantisch), A, i, 50.
\(N\)-Ethynorapaverinum derivatives (Decker and Dunant), A, i, 205.
3-Ethylisooxazoline and its platinum derivative (Maire), A, i, 290.
1-Ethyl-\(\beta\)-pipcocal, \(\omega\)-amino-, (3-aminoethyl-1-ethylpiperidine) and its additive salts(Wohl und Losantisch), A, i, 50.
1-Ethyl-2- and 3-pipoclines and their resolution (Schoitz), A, i, 679.
1-Ethylpiperidine-3-carboxylic acid. See 1-Ethynipeticoinic acid.
Ethyl \(\beta\)-piperidinoethy ketone and its oxime, semicarbazone, pircate, and platinichloride (Blaise and Maire), A, i, 398.
Ethyl\(\alpha\)propylaetoacetic acid, ethyl ester (Clarke), A, i, 493.
Ethyl\(\alpha\)propylaetocet. See \(\gamma\)-isoPropyl-\(\beta\)-pentanone.
Ethyl-\(n\)-propylamine and its additive salts and nitroso-derivative (Comanducci and Arena), A, i, 139.
Ethyl \(\beta\)-propylaminetetketone and its phenylcarbamide (Blaise and Maire), A, i, 398.
Ethylpropylsuccinic acids, \(s\) and \(as\) (Fichter and Kappler), A, i, 660.
Ethyl\(\alpha\)propylsuccinic acids, isomerie, and their calcium salts (Fichter and Glaser), A, i, 660.
3-Ethylpyrazoline and its pircate and phenylcarbamide (Maire), A, i, 290.
4-Ethyquinoline and its additive salts (Blaise and Maire), A, i, 566, 567.
Ethyl-red. See Diethyläsoaconiane iodide.
INDEX OF SUBJECTS. 1323

β-Ethylsulphone-β-phenylpropionic acid (Posner and Baumgartl), A., i, 21.

1-ethyl-Δ2-tetrahydropyridine, 3-cyano-, and its additive salts (Wohl and Losanitsch), A., i, 50.

1-ethyl-Δ3-tetrahydropyridine-3-carboxylic acid, additive salts of (Wohl and Losanitsch), A., i, 50.

Ethylthebromine, β-hydroxy- (Farbenfabriken vorm. F. Bayer & Co.), A., i, 475.

Ethyltheophylline and its additive salts and bromo- (Schwabe), A., i, 45.

5-Ethylthiobarbituric acid (Einhorn), A., i, 315.

β-Ethyl-ψ-thiocarbamide, piperazine and piperolinate of (Wheeler and Jameson), A., i, 917.

5-Ethylthiobarbituric acid and its ethyl ester, preparation of (Farbwerke vorm. Meister, Lücier, & Brüning), A., i, 727.

Ethylthiocarbamic acid, metallic salts and derivatives of (Anschütz), A., i, 326.

2-Ethylthiol-4-methylpyrimidine, 6-amino- and 6-chloro- (Johns), A., i, 917.

2-Ethylthiol-5-methylpyrimidine, 6-thio- and 6-thiocyanate- (Johnson, Storey, and McCollum), A., i, 837.

2-Ethylthiol-4-methylpyrimidine-5-acetic acid, 6-amino-, and 6-chloro-, and its amide (Johnson and Heyl), A., i, 59.

2-Ethylthiol-6-oxo-1-benzylpyrimidine and its 5-methyl derivative (Johnson and Derby), A., i, 1018.

2-Ethylthiol-6-oxo-3-benzylpyrimidine and its 5-bromo- and 5-methyl derivatives (Johnson and Derby), A., i, 1018.

2-Ethylthiolepyrimidine, 5-bromo-6-thiocyanate-, and 6-thiocyanate- (Johnson, Storey, and McCollum), A., i, 837.

2-Ethylthiolepyrimidine-5-carboxylamide, 6-amino-, and its dibromide (Wheeler and Johns), A., i, 839.

2-Ethylthiolepyrimidine-5-carboxylic acid, 6-chloro-, acid chloride, and amide of (Wheeler and Johns), A., i, 839.

2-Ethylthiol-6-pyrimidone-3-acetic acid and its ethyl ester (Wheeler and Liddle), A., i, 693.

2-Ethylthiol-6-pyrimidone-4-acetic acid and its ethyl ester (Wheeler and Liddle), A., i, 693.

Ethyl tiglyl ketone and its p-nitrophenylhydrazone and semicarbazone (Blaise and Herman), A., i, 506.

5-Ethyltrimethylenecarbamide and its piperitate (Tafel and Thompson), A., i, 55.

Ethyltripropylarsenium iodide (Drh and Williams), A., i, 721.

Ethyl vinyl ketone, reactions of, and its diethylacetal (Maire), A., i, 247.

Ethylxanthophanic acid, p-bromophenylhydrazone of (Liebermann and Lindenbaum), A., i, 549.

Etna, fumaroles of (Lacroix), A., ii, 765.

lavas of the recent eruption of (Lacroix), A., ii, 766.

Eucalyptol. See Cineol.

Eucalyptus, occurrence of calcium oxalate in the barks of the (Smith), A., ii, 885.

absence of gum and presence of a new diglucoside in the kinos of the (Smith), A., ii, 886.

Eugenol, oxidation of, by the oxidising ferment of mushrooms (Cousin and Hérissey), A., i, 727.

Eugenol, synthesis of (Behal and Tiffeneau), A., i, 260.

oxidation of (Cousin and Hérissey), A., i, 783.

Eugenyl o- and m-aminobenzoates and their acetyl derivatives, and o- and m-nitrobenzoates (Riedel), A., i, 338.

Eupatorium Rebaudianum, sweet substance from (Rasnack), A., i, 818.

Euphorbia, South African, phytosterols from the latex from (Cohen), A., i, 884.

ψ-Euphorbic acid, α- and ψ-Euphorbic acid, ψ-Euphorboresen, and ψ-Euphorbone (Tschiirch and Lechtenberger), A., i, 196.

Euphorbone and its benzoyl, ψ-nitrobenzoyl, and bromo-derivatives (Emmerling), A., i, 438.

Europium, atomic weight of (Jantsch), A., ii, 282.

Eutectics (Rosenhain and Tucker), A., ii, 1038.

Evaporation apparatus under reduced pressure (Donath), A., ii, 1927.

Evolution in chemistry, principle of (Kurilo off), A., ii, 477.

Excretion of bromides by the kidney (Hale and Fishman), A., ii, 611.

of cholesterol by the dog (Dorée and Gardner), A., ii, 514.

of creatine and creatinine in health and disease (van Hoogenhuyze and Verploegh; Shaffer), A., ii, 971.

of creatine and creatinine in hepatic disease (Mellanby), A., ii, 54.
Excretion of conjugated glycuronic acid in the bile (Bial), A., ii, 611.
of hexamethyleneetriamine in bile and pancreatic juice (Crowe), A., ii, 410.
of iodine, comparative investigations on the, after administration of potassium iodide and saloliodin (Basciu), A., ii, 521; (Abderhalden and Kautzsch), A., ii, 611.
of nitrogen, effect of ether anaesthesia on the (Hawk), A., ii, 410.
of nitrogen in dogs, influence of potassium cyanide on the (Welker), A., ii, 411.
of sugar, action of various chemical substances on the (Baer and Blum), A., ii, 122.
of sugar in healthy men (Schön dorff), A., ii, 311.
of sulphurous acid in man after administration of sodium sulphite and sulphurous acid in combination with sodium salt (Franz and Sonntag), A., ii, 714.
of urobilin in disease (Surveyor), A., ii, 1057.
of urochrome in man (Dombrowski), A., ii, 212.
Expansion and electrical resistance of metals, relation between the (Broniewski), A., ii, 147.
Explosive crystallisation. See Crystallisation.
Extraction, continuous, with a solvent of inconstant boiling point, simple arrangement for (Wörner), A., ii, 651.
Extraction apparatus (Kulka), A., ii, 937.
new reflux condenser for (Merkel), A., ii, 478.
for liquids by means of ether (Sirska), A., i, 533.
for extracting a solid and simultaneously filtering the solution so obtained (Record), A., ii, 575.

F.
Facoprotein (Bottazzi and Scalinci), A., ii, 1054.
Feces, estimation of fat in, by the Kumagawa-Suto method (Inaba), A., ii, 439.
estimation of indole in (v. Moraczewski), A., ii, 441; (Gorter and de Graaff), A., ii, 783.
estimation of nitrogenous metabolism products in (Stützer, Merres, and Seidler), A., ii, 443.
Fallow (Krüger and Heinze), A., ii, 61.
"Farine de Netté" (Goris and Créte), A., ii, 218.
Farm crops. See Crops.
Fat, production of, from proteins (Bog danoff), A., ii, 206.
saponification of, by means of hydroxylamine (Morelli), A., i, 758.
influence of the products of reaction on the hydrolysis of, by pancreatic juice (Kalaboukoff and Terboine), A., ii, 1050.
behaviour of, towards calcium carbonate (Künkle and Schwedhelm), A., i, 494.
catalytic reduction of (Paul and Roth), A., i, 599.
digestion of (Levites), A., ii, 960.
absorption of, from intestinal loops in dogs (Plant), A., ii, 1050.
isoilation of cholesterol from (Salkowski), A., i, 980.
percentage of iron in (Glikin), A., ii, 407.
rancid, certain volatile and non-volatile compounds formed in (Scala), A., i, 387.
in milk. See under Milk.
the ethyl ester value of (Hanus and Stekli), A., ii, 641.
determination of the saponification number of (Mastbaum), A., ii, 439.
estimation of (Bogdanoff), A., ii, 206.
flask for the estimation of (Dubois), A., ii, 641.
estimation of, in cocoa (Kreutz), A., ii, 641.
estimation of, in, in food-stuffs by the Kumagawa-Suto method (Inaba), A., ii, 439.
and unsaponifiable matter, estimation of, in tissues (Kumagawa and Suto), A., ii, 351; (Berntrop), A., ii, 544.
estimation of, in milk. See under Milk.
See also Ochoco fat.
Feiling's solution, reduction of, to metallic copper (Neogi), A., ii, 848.
the keeping power of, and the estimation of reducing sugars with it (Watts and Tempany), A., ii, 437.
Felspar, soda, existence of a monoclinic, isomorphous with orthoclase (Barbier and Prost), A., ii, 863.
apoFenchane, amino-, constitution of (BOUVEAULT and LEVALLOIS), A., i, 194.
Fenchene, synthesis of, from nopinine (WALLACH), A., i, 297.
dl-Fenchene and its dibromide (WALLACH and VIVCK), A., i, 811.
apoFenchene, constitution of, and its hydrochloride (BOUVEAULT and LEVALLOIS), A., i, 193.
isofenchocamphoric acid and its silver salt (WALLACH and VIVCK), A., i, 811.
Fenchene, establishment of the constitutional formula of (BOUVEAULT and LEVALLOIS), A., i, 193.
comparison of, with α-methylcamphor (GLOVER), T., 1285; P., 151.
separation of, from camphor (SEMMLER), A., i, 37.
isofenchene and its oxime and semicarbazone and bromo-derivative (WALLACH and VIVCK), A., i, 811.
isofenchyl phenylcarbamate (WALLACH and VIVCK), A., i, 811.
Fermentation, studies in (SLATOR), T., 217; P., 11.
the phenomena of, from the catalytic point of view (SCHADE), A., i, 136.
part played by Bacteria in the formation of higher alcohols during (FRINGESHEIM), A., ii, 723.
consumption of malic acid in (MESTREZAT), A., ii, 723.
acetic, formation of aldehydes or ketones during (FARNSTEINER), A., i, 318.
alcoholic, the mechanism of (SLATOR), T., 217; P., 11.
proof, by means of the chromatogram method, that hydrogenase takes an active part in (GRUSS), A., i, 491.
constitution of aqueous solutions, and the influence of salts on (VANDEVELDE), A., ii, 216.
role of reductase in (PALLADIN), A., i, 589.
formation of acetaldehyde in (TRILLAT; KAYSER and DEMOLON), A., i, 317.
production of succinic acid during (EHRlich), A., ii, 416.
butyric acid (BUCHNER and MEISENHEIMEN), A., ii, 525.
cell-free, occurrence of formaldehyde in (LIEBMEFF), A., i, 747.
lactic acid, action of small quantities of metals on (RICHERT), A., ii, 880.
Fermentation processes, graphic method of registering (POA), A., i, 746.
Fermented liquids containing other fixed and volatile acids, method of estimating succinic acid in (POZZI-ESCOT), A., ii, 993.
Ferments. See Enzymes.
Ferns, transitory presence of hydrogen cyanide in (GRESHOFF), A., ii, 725.
Ferrimalic acid, complex salts of (MATSUI), A., i, 853.
Ferrinitrososulphides (CAMBI), A., ii, 852.
Ferripyrophosphoric acid and its salts (PASCAL), A., ii, 193.
Ferrisalicylic acids and their bromo-derivative and their esters (HOFPPGARTNER), A., i, 891.
Ferro-alloys, production of (GREENWOOD), T., 1496; P., 189.
estimation of carbon in, by means of an electric furnace (JOHNSON), A., ii, 630.
Ferrochrome with high carbon content, assay of (CAFFIN and DHUIQUE-MAYER), A., ii, 538.
Ferro-compounds, new method of attacking (NICOLARDOT), A., ii, 1074.
Ferro-magnetic substances, specific heat and molecular magnetic field of (WEISS and BECK), A., ii, 659.
Ferronitrosulphides (BELLUCI and de CESARIS), A., ii, 499.
probable constitutional formula of the (BELLUCI and de CESARIS), A., ii, 593.
See also Roussin's salts.
Ferropyrrophosphates (PASCAL), A., ii, 193.
reducing power of (PASCAL), A., ii, 500.
Ferro-silicon, chemical behaviour of high percentage (HAAS), A., ii, 110.
novel method of attacking (NICOLARDOT), A., ii, 1074.
Ferro-vanadium, simultaneous volumetric estimation of iron and vanadium in (WARYNSKI and MIVIANI), A., ii, 736.
Fertilisers. See Manures.
Fever, xanthine as a cause of (MANDER), A., ii, 54.
Fibrin, influence of the reaction of blood-plasma on the formation of (PETEIN), A., ii, 605.
the swelling of (FISCHER), A., i, 929.
Fichtelite from Borkovice, Bohemia (PLZAK and ROSICKY), A., ii, 395.
Filter for filtering solutions of definite concentration at a temperature either above or below that of the surrounding medium (LEVITEN), A., ii, 576.
Filters, relative efficiency of (BULLOCH, CHAW, and ATKIN), A., ii, 314.
Filters, grain of, and growth of bacteria through them (Craw), A., ii, 314. See also Ultra-filters.

Filtration apparatus (Wislicenus), A., ii, 576.

Fish muscle, hydrolysis of (Osborne and Hety), A., ii, 1055.

Fishes, gastric digestion in (van Herwerden), A., ii, 872.

toxicity of silver salts to (Pigorini), A., ii, 412.

brain of. See Brain.

Flavanthren, fish, pancreatic diabetes in (Dia- 

Flame, Bunsen. See Bunsen flame.

Flame reactions and colorations, simple gas burner contrivance for showing (Thorner), A., ii, 341.

Flames of various kinds, spectroscopic study of (Hemsalech and de Watteville), A., ii, 336.

coloured, apparatus for producing (Goldschmidt), A., ii, 787.

Flavanthren, reduction products of (Scholl and Neovius) A., i, 740.

products of reduction of, and the relation between their colour and constitution (Scholl and Holder- 

mann), A., i, 696.

Flavanthrine and its hydrate and Flavanthrinol (Scholl and Holdermann), A., ii, 696.

Flavanthrinol hydrate (Scholl and Neovius), A., i, 740.

Flavone group (Tambor), A., i, 350, 358.

Flesh, inosite in (Rosenberger), A., ii, 1055.

Flour, wheat, detection of rice starch in (Peltisorot), A., ii, 236.

Flowers, indole in (Weehuizen), A., ii, 1065.

Fluidity and viscosity (Bingham), A., ii, 1017.

Fluoran, quinonoid ester salts of, and 2:7-dichloro- (Green and King), A., i, 1003.

Fluorene, hydrogenation of (Schmidt and Mezger), A., i, 16.

oxidation of (Law and Perkin), T., 1637; P., 195.

condensation of, with alkyl nitrates and nitrates by means of potassium ethoxide (Wislicenus and Waldmüller), A., i, 973.

sodium derivative of (Weissgerber), A., i, 873.

perhydride (Schmidt and Mezger), A., i, 17; (Spiegel), A., i, 331.

Fluorene, 2-amino-, and its reactions (Austin), T., 1765; P., 200.

Fluorene, 9-amino-, and its isomeride, and their derivatives (Schmidt and Stützel), A., i, 415.

9-bromo-9-nitro-, 9-nitro-, and 9-iso- 

nitrato-, and its metallic salts (Wislicenus and Waldmüller), A., i, 973.

Fluorene series (Daufresne), A., i, 164.

N-α Fluroene-9-naphthacridine, preparation of (Austin), T., 1766; P., 200.

Fluorenone, 3-nitro-, and its oxime (Schmidt and Sölle), A., i, 997.

Fluorenedicarboxylic acid, esters and ester-salts of (Lux), A., i, 873.

Fluorenoneoxime (Wislicenus and Waldmüller), A., i, 973.

Fluorescein, the chromogen of (Kehrmann and Dengler), A., i, 1002.

Fluorescence and chemical constitution (Kaufmann), A., ii, 5.

and colour, relation of, to constitution (Sillbrad and Roy), P., 204.

luminescence, and chemical constitution (Hantsch), A., ii, 446.

and photo-electric sensitiveness of organic substances (Stark and Steubing), A., ii, 746.

change of the colour of, with the solvent (Ley and v. Engelhardt), A., ii, 746.

ultra-violet, of cyclic compounds (Ley and v. Engelhardt), A., ii, 911.

of organic compounds (Stark and Steubing), A., ii, 911.

of platinocyanides (Ley), T., 1446; P., 178.

Fluorescent substances, action of, on enzymes (Jamada and Jodlbauer; Zeller and Jodlbauer), A., i, 239.

action of, in yeast and yeast press juice (v. Tappeiner, Kurzmann, and Locher), A., i, 239.

Fluorides. See under Fluorine.

Fluorine in wines (Carles), A., ii, 318.

compounds, detection of, in wines (Vandam), A., ii, 63, 775.

Fluorides, inhibiting action of, on lipase, and test for, in food products (Amberg and Loevenhart), A., i, 235.

Hydrofluorides of some organic bases (Weinland and Reischle), A., i, 974.

Hydrofluosilicic acid, estimation of (Hönig), A., ii, 65.
Fluorine, estimation of small amounts of (Steiger), A., ii, 426.
See also Halogens.
Fluoro-compounds, organic, heat of formation of (Swarts), A., ii, 354.
See also under the parent Substance.
9-Fluorocarbamide and s-9-Fluorophenylcarbamide (Schmidt and Stützel), A., i, 415.
Fongisterol and its acetate, and ergosterol (Tanret), A., i, 637.
Food, preserved, corrosion of tinned containers by acids and by the contents (Lehmann), A., ii, 389.
Foods, aspartic and glutamic acids as (Andrik and Velich), A., ii, 307.
cyanogenetic glucosides in (Henry and Auld), A., ii, 619.
phosphorus in certain (Heubner and Reeb), A., ii, 1052.
detection of boric acid in (Mannich and Priest), A., ii, 429.
detection of boric acid in, by means of turmeric paper (Lavalle), A., ii, 1896.
detection and estimation of boric acid, benzoic acid, and salicylic acid in (v. Generisch), A., ii, 906.
detection of formic acid in (Woodman and Burwell), A., ii, 639.
detection of “saccharin” and other artificial sweetening materials in (Bianchi and di Nola), A., ii, 1079.
estimation of fat in, by the Kumagawa-Suto method (Inaba), A., ii, 439.
estimation of malic acid in (Cwles), A., ii, 904.
modification of Kjeldahl’s process for estimating nitrogen in (Corradi), A., ii, 130.
estimation of phosphoric acid in (Wörner), A., i, 732.
estimation of sulphuric acid in (Lai), A., ii, 593.
rapid estimation of water in (Thörner), A., ii, 222.
Formaldehyde (formalin), preparation of (Orloff), A., i, 77, 761.
formation of, from methyl alcohol (Orloff), A., i, 77.
formation of, in solutions of sugar (Kamray), A., ii, 994.
ocurrence of, in cell-free fermentation (Lebredeff), A., i, 747.
simple reaction for producing the vapour of (Carteret), A., i, 393.
constitution of aqueous solutions of (Delépine), A., i, 393.

Formaldehyde, aniline, and sodium hyposulphite, interaction of (Gesellschaft für Chemische Industrie in Basel), A., i, 151.
action of, on secondary aromatic amines (v. Braun), A., i, 664.
rongalite and bases (Binz and Isaac), A., i, 940.
action of, on starch (Reichard), A., i, 606.
action of zinc carbonate on solutions of (Löb), A., i, 715.
action of zinc dust and iron on solutions of (Löb), A., i, 764.
solid polymerides of (Auerbach and Barschall), A., i, 131.
sodium hyposulphite, so-called (v. Meyer), A., i, 132.
hyposulphite compound, analysis of (Greeves), A., ii, 741.
reactions of (Reychler), A., i, 130; (Todtenhaupt), A., i, 940.
detection of (v. Fillingen), A., ii, 902.
colour test for (Goldetz), A., ii, 330.
See also Paraformaldehyde.
Formaldehyde-lactose (Rosenberg), A., i, 320.
Formaldehydephenylhydrazone, nitrocyanno- (Steinkopp and Bohrmann), A., i, 327.
Formaldehydesulphonylic acid. See Rongalitic acid.
Formaldehydesulphonylic acid, salts, preparation of (Badische Anilin- & Soda-Fabrik), A., i, 605.
sodium salt. See Rongalite.
zinc basic salt, sparingly soluble, preparation of (FARBWERKE VOM. MEISTER, LUCIUS, & BRÜNING), A., i, 133.
Formalidbenzyl disulphoxide (Fromm and Gaupp), A., i, 970.
Formalin. See Formaldehyde.
Formazylacrylic acid and its salts and ethyl ester (Henrich and Thomas), A., i, 114.
Formic acid, quantity of, in honey (Farnsteiner), A., ii, 639.
preparation of concentrated (Chemische Fabrik Grünau, Landschoff, & Meyer), A., i, 598.
and acetic acid, rates of distillation of (Richtmond), A., i, 754.
fermentation of, by Proteus vulgaris (Franzen and Braun), A., ii, 215.
detection of (Fenton and Sisson), A., ii, 243.
test for, in glacial acetic acid (Ost and Klein), A., ii, 903.
detection of, in foods (Woodman and Burwell), A., ii, 639.
Formic acid, detection of, in honey (Merl), A., ii, 991.

Formic acid, calcium salt, behaviour of, in the organism (Bonanni), A., ii, 213.

complex chromium salts (Werner, Jovanovits, Aschkinasy, and Fosselyl), A., i, 335.

Formic acid, benzyl ester (Bacon), A., i, 815.

ethyl ester, aspersionification of, by water in presence of acids as catalytic agents (Lapworth), P., 100.

Formyl-L-histidine (Fischer and Cone), A., i, 1005.

N-Formylpropionamide (Einhorn), A., i, 609.

Formyl-L-tyrosine methyl and ethyl carbonates (Fischer), A., i, 887.

Fractional distillation. See under Distillation.

Fractionating column (Habermann), A., ii, 17.

Frankincense, oil of (Haensel), A., i, 665.

Freezing of hydrosols (Robertag, Feist, and Fischer), A., i, 1024.

Freezing point and boiling point of concentrated aqueous solutions and the question of the hydration of the solute (Johnston), A., ii, 661.

of mixtures, apparatus for determining (Scheuer), A., ii, 928.

in physiological fluids, analysis of the lowering of the (Tezner), A., ii, 16; (Tezner and Roska), A., ii, 810.

apparatus for determining (Dehuyzen), A., ii, 661.

determinations. See also Cryometric and Cryoscopic measurements.

Freezing point curves of mixtures of naphthalene and phenol (Yamamoto), A., ii, 928.

and melting point curves of binary systems when the solid phase is a mixture (amorphous solid solution or mixed crystals) of the two components (Van Laar), A., ii, 808.

Freezing point diagrams of the binary systems, platinum—arsenic, and bis-muth—arsenic (Friedrich and Leroux), A., ii, 300.

of metallic sulphides and their mixtures (Friedrich and Schöen), A., ii, 281.

Freezing point surfaces of the system, chlorobenzene, naphthalene, and phenol (Hirobe), A., ii, 928.

Friedel and Crafts’ reaction (Bøesken), A., i, 189; (Heller and Schülke), A., i, 994.

Friedel and Crafts’ reaction, new catalytic effect of aluminium chloride in the (Böttker), A., i, 621.

formation of mixtures of isomerides of constant melting point in (Ferrier and Caille), A., i, 349.

reciprocal displacement of hydrocarbon groups in (Duval), A., i, 277.

Frogs, influence of temperature on motor and sensory nerves of (Hapemann), A., ii, 513.

action of alcohols and of wines on (Nazarri), A., ii, 973.

action of caffeine on (Jacozi and Golowinski), A., ii, 1061.

glycogen in, during inanition (Pflüger), A., ii, 52.

respiratory metabolism of the isolated spinal cord of (Winterstein), A., ii, 509.

urinary secretion in (Cullis), A., ii, 518.

heart. See under Heart.

kidney. See Kidney.

muscle. See Muscle.

sartorius, refractory period of the (Bazett), A., ii, 305.

skin, the permeability of (Bayliss), A., ii, 712.

spawn, glycogen of (Haensel), A., ii, 769.

Fructosazine. See L’évulosaizine.

d-Fructose. See L’évulose.

Fruit, the catalytic and hydrolytic enzymes acting during the process of ripening of (Tallarico), A., ii, 724.

nitrates in (Richardson), A., ii, 208.

Fruits, tropical, rapid change in composition of, during ripening (Geerligs), A., ii, 977.

detection and estimation of benzoic acid in (Reed), A., ii, 74.

Fulgides, crystallography of the (Tobrffy), A., i, 735.

phototrophy of (Stobbe), A., ii, 339.

Fulminic acid, mercury salt, constitution of, and the action of mercury diethyl on (Grigorowitsch), A., i, 251.

Fulvenes, acyclic (Staudinger), A., i, 411.

Fumaric acid, alkaloidal salts, and their optical activity (Hilditch), T., 704; P., 61.

Fumaric acid, triphenylmethyl ester (Anschütz), A., i, 331.

Fumaroles of Etna and Vesuvius (Lacroix), A., ii, 766.

Fungi, influence of the chemical constitution of the nitrogenous nutrient on the fermentative action and growth of certain (Pringsheim), A., ii, 316.
Fungi, formation of fusel oil by certain (Pringsheim), A., ii, 316.
de-amidising enzymes of (Pringsheim), A., ii, 773.
higher, chemistry of the (Zellner), A., ii, 216.
Funnel, boat (Stoltzzenberg), A., ii, 1071.
turbine, for mixing solutions (Gawalowski), A., ii, 939.
Furan, hydrogenation of (Bourgignon), A., i, 280.
Furfuraldehyde, diacete from (Law), A., i, 321.
Furfurylacetone acid (pyromucylactone acid), ethyl ester, reactions of (Torrey and Zanetti), A., i, 840.
Furfurylidene pyruvic acid, iodo-lactone from (Bougault), A., i, 559.
Furnace gases, apparatus for the automatic analysis of (Keane and Burrows), A., ii, 715.
Furorin, aklylation of (Irvine and McNicol), T., 1008; P., 192.
Furoxan, constitution of (Wieland and Semper), A., i, 108.
Furoxandicarboxylic acid, ethyl ester, and its reactions (Wieland and Gmelin), A., i, 1013.
3-Furyl-5-pyrazolone and its picrate, acetyl, benzylidene, and phenylcarbinol derivatives (Torrey and Zanetti), A., i, 840.
Fusel oil, formation of, by certain fungi (Pringsheim), A., ii, 316.
formation, the depression of (Pringsheim), A., ii, 723.
Fusion surfaces. See Freezing point surfaces.

G.

Gabbroitic rocks from Neurde, Silesia, analyses of (Tannhäuser), A., ii, 1047.
Gadolinitum fluoride (Popovici), A., ii, 283.
sulphide (Erdmann and Wirth), A., ii, 695.
Galactose, behaviour of, towards dilute sodium hydroxide (Meisenheimer), A., i, 319.
Galactose-0- and -m-nitrophenylhydrzone (Recclaire), A., i, 1014.
Galenical preparations made from leaves and from other parts of plants, reaction distinguishing between (Richaud and Bidot), A., ii, 444.
Gallic acid, electrolytic oxidation of (A. G. and F. M. Perkin), T., 1186; P., 149.
action of reducing agents on (Gardner and Hodgson), P., 272.
Gallocarboxylic acid mono- and trimethyl ethers (Feist), A., i, 102.
Galloycyanin dyes, condensation of, with amino-compounds (Grandmougin and Bodmer), A., i, 572.
Gallotannic acid, constitution of (Lloyd), A., i, 347.
P-Galloyloxybenzoic acid (Fischer), A., i, 893.
Gas, modified form of Saint-Claire Deville’s apparatus for the continuous production of (Grignard), A., ii, 827.
measurement of a homogeneous chemical change in a (Clarke and Chapman), T., 1638; P., 190.
high pressure, simple regulator for (Le Rossignol), A., ii, 827.
illuminating, estimation of benzene in (Dennis and McCarthy), A., ii, 435.
coal. See Coal gas.

Gas analysis (Anema and van Deventer), A., ii, 221; (Wuute), A., ii, 891.
problems of (Anema and van Deventer), A., ii, 221; (de Voldere and de Smet), A., ii, 425.
apparatus, new (Ross and Leather), A., ii, 628.
accurate form of, for commercial and other purposes (Bone and Wheeler), A., ii, 221.
Hempel’s, improvements in (de Voldere), A., ii, 61.
technical, estimation of hydrogen in (Hauser), A., ii, 425.

Gas burettes. See Burettes.

Gas burner contrivance, simple, for showing flame reactions, combustion phenomena, and flame colorations (Thorner), A., ii, 341.

Gas current pressure regulator (Johnson and Buchi), A., ii, 270.

Gas generating apparatus, Erper’s (Gutmann), A., ii, 826.
for analytical purposes (Müller), A., ii, 129.

Gas laws, simple demonstrations of the (Dehn), A., ii, 355.

Gas-pipette, compound (Fleissner), A., ii, 891.

Gas thermometer. See under Thermochemistry.

Gas volumes, new instrument for reducing, to standard conditions (Davis), A., ii, 666.

monatomic, electric discharge in *(Soddy and Mackenzie)*, A., ii, 151.

rare, presence of, in the atmosphere at different heights *(Teisserenc de Bort)*, A., ii, 763.

of thermal waters *(Moure and Biquard)*, A., ii, 277.

produced in the alimentary canal of goats *(Boycott and Damant)*, A., ii, 122.

**Gastric digestion.** See Digestion.

juice in children, chemical composition of *(Sommerfeld)*, A., ii, 403.

action of alkalis on the protein-ferment of *(Tichomirolloff)*, A., ii, 404.

the Leo process for the estimation of acidity of the monometallic phosphates in *(Barberio)*, A., ii, 532.

secretion, influence of bromine on *(Togami)*, A., ii, 872.

action of therapeutic agents on the *(Feigl)*, A., ii, 311.

**Gedrite** from Canada *(Evans and Bancroft)*, A., ii, 604.

**Gelatin,** physical modifications of, in presence of electrolytes and non-electrolytes *(Larguier des Bancel)*, A., i, 283.

phenomena of the "precipitation" and "insolubilisation" of *(A. and L. Lumière and Seyewetz)*, A., i, 710.

**Gelatins,** estimation of sulphurous acid in *(Pâde)*, A., ii, 893.

**Gelatin jellies,** diffusion of albumin into *(Möllhausen)*, A., ii, 670.

**Gelatin solutions,** behaviour of, towards naphthols or mixtures of naphthols with formaldehyde *(Weinschenk)*, A., i, 377.

**Gelatinisation,** the process of *(Levites)*, A., ii, 161, 264, 476.

**Gelatose** as colloid producer *(Liesegang)*, A., ii, 476.

**Gelatoses** *(Skraup and Humbelberger)*, A., i, 711.

**Cyclic** **Geranic acids** and their anilides, and their conversion into citrals *(Merling)*, A., i, 653.

**Geranic series,** mechanism of the ring formations in the *(Tiffeneau)*, A., i, 500.

**Gaseous mixtures,** influence of the silent discharge on explosive *(Fassbender)*, A., ii, 561.

conductivity of, at the moment of explosion *(de Muynck)*, A., ii, 345.

**Gaseous reactions** which are photo-chemically sensitised *(Weigert)*, A., ii, 5.

**Gaseous substances,** velocity of absorption of, by solid substances *(Hantzsch and Wiegner)*, A., ii, 158.

**Gases** subjected to the action of spark discharge or arc light, certain phenomena in *(v. Traubenbergen)*, A., ii, 1012.

extraction of, contained in metals *(Boudouard)*, A., ii, 109.

dielectric constants of, at high pressures *(Tangl)*, A., ii, 558.

inflammation of, at the end of a metallic rod *(Meunier)*, A., ii, 276.

combustion of, by incandescence in presence of oxidisable and of non-combustible substances *(Meunier)*, A., ii, 376.

which are in a state of motion, reaction velocity in *(Bodenstein and Wolgast)*, A., ii, 162; *(Langmuir)*, A., ii, 1020.

use of sodium as a desiccating agent for *(Matignon)*, A., ii, 377.

in liquids, cryoscopic investigations on solutions of *(Falciola)*, A., ii, 1015.

condensation nuclei produced by cooling, to low temperatures *(Owen and Hughes)*, A., ii, 565.

absorption of, by rubber tubing *(Ditmar)*, A., ii, 159.

influence of colloids on the absorption of *(Findlay and Harby)*, A., ii, 1024.

occluded in a special nickel steel *(Belloc)*, A., ii, 582.

inactive, percentage of, in the atmosphere; a correction *(Ramsay)*, A., ii, 688.

ionised *(Blanc)*, A., ii, 753.
Geranyl benzoate and methyl ether (Bacon), A., i, 815.
Germanium silver sulphide. See Argyrodite.
Gland, digestive, of the crayfish (Bradley), A., ii, 405.
Lymph, spleen, and thymus, occurrence of choline in (Schwarz and Lederer), A., ii, 965.
Thymus, nucleic acid of. See Nucleic acids.
Thymamine from the (Nelson), A., i, 1030.
Thyroid, relationship of, to the physiological action of adrenaline (Pick and Pineles), A., ii, 875.
Choline, the depressor substance in the (v. Fürth and Schwarz), A., ii, 965.
Glands, physiology of the (Haas), A., ii, 874.
Glass, violet coloration produced in, by the influence of light (Maschhaupt), A., ii, 1003.
Deposition of copper mirrors on (Neogli), A., ii, 848.
Colourless, some effects of sunlight on (Gortner), A., ii, 183.
Dark-coloured, production of a (Sackur), A., ii, 1036.
Silicate, action of phosphoric acid on (Hüttener), A., ii, 838.
Glass thermostats. See under Thermochmistry.
Glaucono-hydrolagic acid (Nierenstein), A., i, 548.
Glaucohyllins (Wilsätter and Pfannenstiel), A., i, 198.
Gliadin from rye, hydrolysis of (Osborne and Clapp), A., i, 115.
Estimation of (Mathewson), A., ii, 443.
Polariscope method for the estimation of (Shaw), A., ii, 240.
Globularia Alyum, rutin from (Wunderlich), A., i, 559.
Globulin from the almond, hydrolysis of the (Osborne and Clapp), A., i, 115.
From the yolk of Squiatus acaenthias (Alsberg and Clark), A., ii, 963.
Antitoxic (Banzhaf; Banzhaf and Gibson), A., ii, 412.
Globulin ions, measurement of the molecular mass of (Sutherland), A., i, 930.
Glow. See under Electrochemistry.
Glucinum salts, structure of (Glassmann and Novicky), A., i, 120; (Tantar and Kubovskj), A., i, 166, 502, 758.
Glucinum salts, influence of, on plants (Kanomata), A., ii, 616.
Glucinum basic sulphates, soluble (Parsons, Robinson, and Fuller), A., ii, 105.
D-Gluconic acid, alkaloidal salts (Nef), A., i, 6.
Glucosamine, behaviour of, and of the first product of its transformation in the animal body (Stolte), A., ii, 50.
D-Glucose. See Dextrose.
Glucosanilide, preparation, alkylation, and mutarotation of (Irving and Gilmour), T., 1434; P., 186.
Glucosehydrazone, constitution of (Irvinle and Gilmour), T., 1429; P., 186.
Glucosexime, preparation and alkylation of (Irving and Gilmour), T., 1435; P., 186.
Glucosides, synthesis of (Ryan and Ebrill), A., i, 716.
Baptisia (Gorter), A., i, 97.
Cyanogenetic, in feeding-stuffs (Henry and AuH), A., ii, 619.
of Linaria (Klobb), A., i, 903.
and sugars, application of bio-chemical methods for the detection of, in Taxee (Lefebvre), A., ii, 57.
Glucosides. See also:
Agrostemmia acid.

Glucothionic acid (Mandel and Newberg), A., i, 1029.
Glutaconic acid and its ethyl ester action of diazobenzene on (Henrich and Thomas), A., i, 114.
Glutamic acid in various keratins (Anderhalten and Fuchs), A., i, 1029.
INDEX OF SUBJECTS.

Glycide, nitro- (Will, Haanen, and Stöhrer), A., i, 384.

Glycide acids, Bβ-disubstituted, esters, preparation of (Darzens), A., i, 91.

Glycine (aminooacetic acid), condensation of, with aminomenediaryloxy acid (Godden), T., 1172; P., 144.

Glutamic acid, methyl ester, action of magnesium phenyl bromide on (Fecht), A., ii, 916.

Glutaredialdehyde and its polymeride and bisnitrophenylhydrazone (Harries and Tank), A., i, 517.

Glutaric acid, its conversion into n-butyric acid (Brasch and Neuberg), A., i, 860.

and aspartic acid as foodstuffs (Andrlik and Velich), A., ii, 307.

Glycinol, Glutinol, Glutonic acid, and Glutinolic acid (A. and H. v. Euler), A., i, 40.

Glutardialdehyde and its polymeride and bisnitrophenylhydrazone (Harries and Tank), A., i, 517.

Glutaric acid, methyl ester, action of magnesium phenyl bromide on (Fecht), A., ii, 916.

Gluten, a modification of the properties of, by sulphurous acid (Dugast), A., i, 709.

Glycerides, theory of the hydrolysis of the (Wegscheider), A., i, 499; ii, 165.

saponification of, during ester exchanges in homogeneous systems (Kremann), A., i, 120; ii, 1021; (Stritar and Fanto), A., ii, 677, 1021.

diacetyl, preparation of (Ulzer, Batik, and Sommer), A., i, 310.

Glycerol, C\textsubscript{10}H\textsubscript{20}O\textsubscript{3}, from sabina glycerol (Wallach), A., i, 432.

Glycerol, density, refractive index, surface tension, and viscosity of various mixtures of water and, at 18° (Martinez-Strong), A., i, 307.

and water, explanation of the viscosity curve for mixtures of (Carracido), A., ii, 758.

colour of (Spring), A., i, 118.

esterification of phosphoric acid by (Prunier), A., i, 2.

comounds of, with metallic salts (Grün and Bockisch), A., i, 934.

ethers with phenols, new method of formation of (Schivkovitch), A., i, 978.

Glyceryl monomethyl ether (α-methylvin) (Grün and Bockisch), A., i, 935.

diphenyl ether (Boyd and Marle), T., 840; P., 92.

diestearophosphate and its dibromo-derivative (Ulzer and Batik), A., i, 599.

di-p-tolyl ether (Boyd and Marle), T., 838; P., 92.

esters of saturated monobasic fatty acids, action of concentrated sulphuric acid on (Thieme), A., i, 498.

α- and B-naphthyl, phenyl, and α-, m-, and p-tolyl ethers (Schivkovitch), A., i, 978.

nitrites and their acetates and benzoates (Will, Haanen, and Stöhrer), A., i, 384.

Glycine, ethyl ester, reduction of (Fischer), A., i, 323.

Glycines, aromatic, preparation of (Imbert & Consortium für Electrochemische Industrie), A., i, 875.

Glycine anhydride and its methyl homologues, nitration and acetylation of (Franchimont and Friedmann), A., i, 509.

Glycine hispida. See Soja bean.

Glycine-N-dithiocarboxylic acid. See Carbaminoacetic acid, dithio-.

Glycocholic acid (Pictreu), A., i, 959.
sodium salt, preparation of (Lewis), A., i, 326.

Glycochrysonar (Hesse), A., ii, 419.

Glycogen, formation of, by yeast (Pavy and Bywaters), A., ii, 56.
can the liver form, from optically active amino-acids? (Grube), A., ii, 516.

the smallest molecule from which the liver can make (Grube), A., ii, 307.

transformation of, by enzyme action in embryonic tissues (Mendel and Saiki), A., ii, 207.

general mechanism of the transformation of, into dextrine in the muscles and tissues (Maignon), A., ii, 53.

in frogs during inanition (Pflüger), A., ii, 52.
Glycogen, of frog's spawn (Haensel), A., ii, 769.
in mouse tumours (Haaland), A., ii, 612.
precipitation of (Pflüger), A., ii, 329.
estimation of, by inversion with acids (Grebe), A., ii, 329.
Glycol. See Ethylene glycol.
Glycol-chlorohydrin ethers, alkylene, and their changes (Houben and Förrer), A., i, 73 ; (Hoering), A., i, 119, 497 ; (Houben), A., i, 307, 935.
Glycollic acid, preparation of, by the electrolytic reduction of oxalic acid (Deutsche Gold- & Silberscheide-Anstalt), A., i, 600.
esterification of (Holmberg), A., i, 357.
phenylhydrzone salt (Nee), A., i, 5.
Glyoxylic acid, glucimine salt (Glasmann and Novicky), A., i, 121.
Glyoxylic acid, thio-, antimony salt (Rosenheim), A., i, 246.
dithio-, preparation of (Kalle & Co.), A., i, 605.
Glycollic acids, thio-, antimony and tin compounds of (Holmberg), A., i, 130.
Glycols, aromatic, mechanism of the transposition of phenyl in (Tiffei-neau), A., i, 166.
α-Glycols, compounds of, with metallic salts (Grün and Bockisch), A., i, 934.
Glycolysis (McGuigan), A., ii, 406.
Glycosuria. See Diabetes.
Glycuronic acid, the asymmetric conjugation of (Mayer), A., i, 393.
conjugated, elimination of, in the bile (Bial), A., ii, 611.
and its derivatives, detection of, in the presence of pentoses and in urine (B. Tollens), A., ii, 639 ; (K. Tollens), A., ii, 740.
estimation and colour reactions of (Leefv re and Tollens), A., ii, 74.
Glycydyl-d-alanine, methyl ester, and its hydrochloride (Fischer), A., i, 887.
Glycyld-d-alanyl-d-tyrosine (Fischer), A., i, 325.
Glycyld-d-alanylglycyl-L-tyrosine (Abderhalden and Hirszowski), A., i, 888.
Glyclylaminocetal and its derivatives (Fischer), A., i, 544.
Glycyl a-aminoesteric acid and its sodium salt and anhydryde (Fischer and Kropp), A., i, 773.
Glycyltyrosylglycine (Fischer), A., i, 544.
Glycyltyrosylglycyl-d-alanine (Fischer), A., i, 887.
Glycyl-d-valine and its derivatives (Fischer and Scheibler), A., i, 957.
Glycyrhhetic acid and Glycyrrhetic acid (Tschirch and Gauchmann), A., i, 898.
Glyoxal (oxalic aldehyde) sodium hydrogen sulphite, reaction of, with aromatic amines (Hinsberg), A., i, 453.
Glyxonalones (iminacolones) (Biltz and Horrmann), A., i, 56.
Glyximo peroxides, constitution of (Wieland and Semper), A., i, 108.
Glyoxylase (Granström), A., i, 295.
Glyoxylic acid, action of, on aniline and its homologues (v. Ostromisslensky), A., i, 889.
fermentative change of, in organs (Granström), A., i, 235.
ocurrence and detection of, in human urine (Granström), A., ii, 122.
Glyxylic acid, ethyl ester, alcoholate of (Traube), A., i, 76.
Glyoxynitrophenylacetic acid (Kunc-kei and Flos), A., i, 890.
Goats, alimentary canal of. See Alimentary canal.
Gold, fulminating, preparation of (Jacob- sen), A., ii, 601.
direct action of radium on (Perman), T., 1775 ; P., 214.
action of barium and sodium peroxides on (Meyer), A., ii, 47.
metallic, solution of, in hydrochloric acid in presence of various organic substances (Averkief), A., ii, 859.
solutions, colloidal, optical properties of (Steubing), A., ii, 600.
Gold chloride, reduction of, by charcoal (Avery), A., ii, 391.
solutions, action of sugars on (Vanino), A., ii, 504.
and phosphorus chloride, complex, derivatives of (Levi-Malvano), A., i, 774.
chromates (Orloff), A., ii, 48.
Chlorauric acid, action of silver nitrate on (Jacobsen), A., ii, 601.
Gold sulphones, complex (Rosenheim, Hertzmann, and Pfitze), A., ii, 860.
Gold organic compounds with phosphorus (Levi-Malvano), A., i, 775.
Gold, detection of, by the metaphosphate bead (Donau), A., ii, 434.
Gold, estimation of, by means of sucrose or dextrose (Leidler), A., ii, 327.  
Gold assaying, apparatus for the prevention of acid fumes in (Dard), A., ii, 72.  
Gold ions, equilibrium in (Boze), A., ii, 264.  
Gout (Kionka), A., ii, 972.  
Gramineae, hydrolytic enzyme in the resting seeds of some (Tanaka), A., i, 459.  
Grapes, transformations of the chromogenic matter of, during maturation (Laborde), A., ii, 1064.  
red, origin of the colouring matter of (Laborde), A., ii, 774; (Malvezin), A., ii, 887.  
Graphite, density of (Le Chatelier and Woldgine), A., ii, 177.  
solubility of, in iron (Charpy), A., ii, 110; (Benedicks), A., ii, 275.  
estimation of (Brown), A., ii, 896.  
estimation of ash in (Sadtlner), A., ii, 225.  
colloidal (Acheson), A., ii, 375.  
Green manure. See under Manure.  
Grignard's reaction, applications of (British Association Reports), A., i, 305.  
See also Magnesium organic compounds.  
Grindelia, examination of (Power and Tutin), A., ii, 526.  
Growth, contributions to the chemistry of (Lochhead and Cramer), A., ii, 710.  
chemical studies on (Mendel and Saiki; Mendel and Leavenworth), A., ii, 207.  
Guaiacol, preparation of vanillin from (Roesler), A., i, 348.  
azo-derivatives of (Colombano and Leonardi), A., i, 68.  
ethylene and trimethylene ethers (Gattermann), A., i, 35.  
Guaiacol, o- and p-bromo-, 6-bromo-4-nitro-, and its potassium salts, and 4-bromo-6-nitro-, potassium salts of (Robertson), T., 791; P., 73.  
5-cyano-(isoanilidonitrile) (Mameli), A., i, 18.  
iozo-,(constitution of (Tassilly and Leroid), A., i, 161.  
p-i zo-,(Mameli and Pinna), A., i, 263.  
4- and 5-i zo-,(Mameli), A., i, 18.  
Guaiacolsulphonic acids, o- and p-, separation of (Chemische Fabrik von Heyden), A., i, 161.  
Guaiacum reaction, the mechanism of the (Carlson), A., ii, 644.  
Guaiacum resin oil (Haensel), A., i, 665.  
Guaiacylphosphoric acid and its salts and chloride (Auger and Dupuis), A., i, 529.  
Guansalone, 4-amino- (guanosine), and its additive salts and triacetyl derivative, and compound with benzaldehyde (Pellizzari and Repetto), A., i, 65.  
Guaneide, salts of, with acid dyes (Radberger), A., i, 1001.  
anilinium sulphate, double (Ferraboschi), A., i, 720.  
4-nitroacetylanthranilate (Bogert and Klaber), A., i, 467.  
Guaneide, cyano-. See Dicyanodimide.  
Guandines, picrolonates of (Wheeler and Jamieson), A., i, 253.  
α-Guandinehexoic acid, ω-amino-, synthesis of, and its nitrates (Heckel), A., i, 862.  
Guanine, formation of pure, from nucleic acids (Levene and Mandel), A., i, 586.  
Guanylvic acid (Bang), A., i, 70; (Levene and Mandel), A., i, 587.  
from the pancreas (Steudel), A., i, 70; (v. Fürth and Jerusalem), A., ii, 119.  
of the spleen (Jones and Rowntree), A., i, 437.  
Guignet's green, colour and composition of (Wöhler and Becker), A., ii, 765.  
Guldberg-Avogadro law (Kurbatoff), A., ii, 812.  
l-Gulose, preparation of (Blanksma and Alberda van Ekenstein), A., i, 951.  
transformation of, into l-sorbose (Alberda van Ekenstein and Blanksma), A., i, 136.  
Gum of the almond tree (Huerre), A., i, 606.  
Gypsum, solubility of, in copper sulphate solutions (Bell and Taber), A., ii, 107.  
as a manure (Takeuchi), A., ii, 624.  
See also Calcium sulphate.  

H.  
Häm-agglutination and hämolysis (v. Liebermann), A., ii, 865.  
and its physical basis (Hirschfeld), A., ii, 402.  
Hämateurin and its derivatives (Engels, Perkin, and Robinson), T., 1115; P., 148.
INDEX OF SUBJECTS.

Hæmatozylon and brazilin and their derivatives (Engels, Perkin, and Robinson), T., 1115; P., 148.

Hæmatologic, as (Engels, Perkin, and Robinson), T., 489; P., 54.
as an indicator in the titration of phosphoric acid (Lyons), A., ii, 532.

Hæmin (v. Sirwert), A., i, 436.
and bromo- and iodo- (Merkowicz and Zaleski), A., i, 231.

Hæmoglobin and the leuco-base of malachite-green, reaction between (Buckmaster), A., ii, 643.
influence of, on phagocytosis (Hamburger and Herma), A., ii, 511.
alleged formation of bile acids and bile pigments by the action of trypsin on (Hollis), A., ii, 408.
the aloin test for (Bolland), A., ii, 240.

Hæmoglobin and the leuco-base of malachite-green, reaction between (Buckmaster), A., ii, 709.
drives of, Dennstedt's method for the analysis of (Zaleski), A., ii, 132.
See also Carboxyæmoglobin, Carb-oxymethæmoglobin, Oxyhemoglobin, and Photomethæmoglobin.

Hæmolysins, distribution of the salts in (Wolffel), A., ii, 402.
the chemical (VanDevelde), A., ii, 49, 512.
complex (Tsurasaki), A., ii, 708.

Hæmolysis (Arrhenius), A., ii, 708;
(v. Liebermann), A., ii, 959.
and hæm-agglutination (v. Liebermann), A., ii, 865.
lipolysis, and agglutination (Neu-berg), A., ii, 708.
the mechanism of, by saponin (Meyer), A., ii, 709.
time relations of, on exposure to light of sensitised red blood corpuscles (Harbecke and Jodlbauer), A., ii, 866.
influence of certain proteins and other colloids on (Meyer), A., ii, 513.
and cobra poisoning (Bang), A., ii, 721.

Hæmolysis by snake poison (v. Dun-gern and Coca), A., ii, 866.
by soaps (Friedemann and Sachs; Sachs), A., ii, 866.

Hæmolytic action of mercury salts (Dunin-Borkowski), A., ii, 1049.

Hæmolytic poisons, especially bile salts and soaps (Neufeld and Händel), A., ii, 959.

Hæmopyrrole (Marchlewski and Ret-tinger), A., ii, 710.
action of diazobenzene chloride on (Marchlewski), A., i, 843.

Hair, chemical composition of (Ruth-erford and Hawe), A., ii, 53.

Hallerite from Mestres (Barbier), A., ii, 604.

Halloysite, ratio of alumina and silica in (Sternme), A., ii, 1041.

Halochromism of quinones (Meyer), A., i, 731; (Kehrmann), A., i, 993.

Halogens, new theory of (Bancroft), A., ii, 788.
use of pyridine bases as (Cross and Cohen), P., 15.

Halogens salts. See Perhalogen salts.

activity of, in relation to the metals in general (Schuyten), A., ii, 31, 683.
Pringsheim's method for estimating, in organic compounds (Virgin), A., ii, 1070.
estimation of, in organic chloro-bromo-comounds (Babigny), A., ii, 530.
See also Bromine, Chlorine, Fluorine, and Iodine.

Hardness, chemical composition, crystal-line form, and density, relation between (Pöschl), A., ii, 678.
of solid solutions of metals and of definite chemical compounds (Kur-nakoff and Schentschuschuy), A., ii, 932.

Hariroots, Hungarian, supposed toxicity of (Guignard), A., ii, 58.

Hauerite, action of potassium chlorate on (Spezia), A., ii, 861.

Hay, digestibility of, from water meadows as compared with ordinary hay (Friedländers), A., ii, 1066.
nutritive value of non-proteins in (Kellner), A., ii, 220; (Müller), A., ii, 726.

Hæmatein, methylation of (Engels, Perkin, and Robinson), T., 1140.

Hæmatic acids, salts, esters, and aniline derivatives of, and condensation prod-ucts of the esters (Küster, Lacour, and Nicole), A., i, 303.

Hæmatin (Küster, Lacour, and Nicole), A., i, 303; (Küster and Fuchs), A., i, 555.

Hæmatite crystals, artificial (Munroe), A., ii, 116.

Hæmatoxylin and brazillin and their derivatives (Engels, Perkin, and Robinson), T., 1115; P., 148.

constituted from (Perkin and Robin-son), T., 489; P., 54.

Hæmin (v. Sirwert), A., i, 436.
and bromo- and iodo- (Merkowicz and Zaleski), A., i, 231.

Hæmatite crystals, artificial (Munroe), A., ii, 116.

Hæmatoxylin and brazillin and their derivatives (Engels, Perkin, and Robinson), T., 1115; P., 148.

constituted from (Perkin and Robin-son), T., 489; P., 54.

as an indicator in the titration of phosphoric acid (Lyons), A., ii, 532.

Hæmin (v. Sirwert), A., i, 436.
and bromo- and iodo- (Merkowicz and Zaleski), A., i, 231.

iodo-, Dennstedt's method for the analysis of (Zaleski), A., ii, 182.

Hæmoglobin and the leuco-base of malachite-green, reaction between (Buckmaster), A., ii, 643.
influence of, on phagocytosis (Hamburger and Herma), A., ii, 511.
alleged formation of bile acids and bile pigments by the action of trypsin on (Hollis), A., ii, 408.
the aloin test for (Bolland), A., ii, 240.

Hæmoglobin and the leuco-base of malachite-green, reaction between (Buckmaster), A., i, 709.
drives of, Dennstedt's method for the analysis of (Zaleski), A., ii, 132.

See also Carboxyæmoglobin, Carb-oxymethæmoglobin, Oxyhemoglobin, and Photomethæmoglobin.

Hæmolysins, distribution of the salts in (Wolffel), A., ii, 402.
the chemical (VanDevelde), A., ii, 49, 512.
complex (Tsurasaki), A., ii, 708.

Hæmolysis (Arrhenius), A., ii, 708;
(v. Liebermann), A., ii, 959.
and hæm-agglutination (v. Liebermann), A., ii, 865.
lipolysis, and agglutination (Neu-berg), A., ii, 708.
the mechanism of, by saponin (Meyer), A., ii, 709.
time relations of, on exposure to light of sensitised red blood corpuscles (Harbecke and Jodlbauer), A., ii, 866.
influence of certain proteins and other colloids on (Meyer), A., ii, 513.
and cobra poisoning (Bang), A., ii, 721.
Heart, apparatus for the perfusion of the isolated mammalian (Brodie and Cullis), A., ii, 865.
vagus inhibition and the output of potassium from the (Howell and Duke), A., ii, 209.
action of barium chloride and sodium sulphate on the (Saffidi), A., ii, 520.
action of caesium on the normal and fatty (Saffidi), A., ii, 411.
action of digitalin on the (Huldschinsky), A., ii, 520.
action of digitalis and strophanthus on the (Tiggersteedt), A., ii, 612.
action of digitalis on the vagus (Lhotak v. Lhota), A., ii, 521.
influence of certain poisons in the fibrillar contraction of the (Winterberg), A., ii, 521.
influence of salts and non-electrolytes on the (Benedict), A., ii, 508.
action of strychnine on the nerve fibres of the vagus of the (Frölich), A., ii, 721.
and vessels, the sensory nerves of the, as a factor in determining the action of drugs (Jackson and Matthews), A., ii, 313.
frog's, action of certain metallic ions on the (Gautelet), A., ii, 120.
of Limulus. See Limulus.
of mammals, action of lactic acid on the isolated and surviving (Backman), A., ii, 612.
See also Circulation.
Heart rate, carbon dioxide in the regulation of the (Henderson), A., ii, 210.
Heat. See under Thermochemistry.
Heat stroke and high temperature (Sutton), A., ii, 972.
Hefner lamp, radiation of the (Leder), A., ii, 5.
Helianthin, action of dilute nitric acid on (Fox), A., i, 581; (Hewitt), A., i, 582.
isomerism of (Hantzsch and Hillsche), A., i, 469.
Helical structures (Gaubert), A., ii, 475.
Helium, accumulation of, in geological time (Strutt), A., ii, 922.
xenon, krypton, and neon, percentage of, in the atmosphere (Ramsay), A., ii, 688.
and radioactivity in rare and common minerals (Strutt), A., ii, 649.
Helium in saline minerals, and its probable connexion with potassium (Strutt), A., ii, 923.
and thorium, association of, in minerals (Strutt), A., ii, 144.
in minerals containing uranium (Bordas), A., ii, 505.
rate of production of, from radium (Dewar), A., ii, 921.
rate of production of, from thorium and uranium (Soddy), A., ii, 921.
refractive power of (Schel and Schmidt), A., ii, 333.
refraction and dispersion of (Herrmann), A., ii, 333, 785.
dispersion of (Uthbertson and Metcalfe), A., ii, 545.
refractive index and dispersion of light in (Burton), A., ii, 545.
lines, Zeeman effect for the (Lohmann), A., ii, 152, 243.
argon, and air, magnetic behaviour of, in relation to oxygen (Tänzler), A., ii, 152.
determination of the dielectric constant of (Hochheim), A., ii, 654.
and argon, thermal conductivity of mixtures of (Wachsmuth), A., ii, 351.
condensation of, by expansion (Onnes), A., ii, 490.
a new determination of C P/C o for (Bein and Geiger), A., ii, 99.
liquefaction of (Onnes), A., ii, 944.
genesis of ions by collision of positive and negative ions in (Gill and Pidduck), A., ii, 798.
detection of small quantities of, in minerals (Bordas), A., ii, 430.
Helium atom, number of quasi-elastic bound electrons in the (Erßle), A., ii, 557.
Hemichlorogenic acid and its pentacetyl derivative and their aniline salts (Gorter), A., i, 346.
Hemipinic acid, nitro-, esterification of (Wegscheider v. Rusanov, and v. Dubraw), A., i, 793.
methyl esters, isomerism of (Wegscheider and Strauch), A., i, 794.
Hemp, effect of new nitrogenous fertilisers on (Stöhr), A., ii, 421.
Canadian. See Apocynum cannabinum.
Hempel's apparatus, modification of (Hauser), A., ii, 425.
Δ86-Heptadiene (Reif), A., i, 847.
Heptaloxime (enanthaldoxime), alkylation of (Irvine and Moodie), T. 102.
INDEX OF SUBJECTS. 1337

3:4:5:6:2':3':4':5'-Heptamethoxydiphenyl-
2:6'-dicarboxylic acid and its methyl
ester (HERZIG, TSCHERNE, and V.
BRONNECK), A., i, 548.

Heptane. See β5-Dimethylpentane.

INDEX OF SUBJECTS. 1337

HCycoHeptane and its reduction (WILL-
stätter and KAMETAKA), A., i, 401.

Heptanedicarboxylic acids. See Azel-
ic acids, α5-Dimethylpimelic acid,
Ethylpropyleneurutaric acids, Ethylöse-
propylsuccinic acid, r-β-isoPropyl-
adipic acid, and αα3-Trimethyladipic
acide.

Heptanetetraarcboxylic acid (ANGELI
and MARINO), A., i, 543.

Heptanetricarboxylic acid, its iso-
meride, and their anhydrides (ANGELI
and MARINO), A., i, 544.

cycloHeptene ozonide (HARRIES and
tANK), A., i, 517.

Heptene series, studies in the (ZELIN-
sky and PRSHEVALESKY), A., i, 845.

Δβ-Hepten-5-ol and its acetate and
chloride (REFI), A., i, 847.

Hepten-5-ols. See also Methylhexen-
5-ols.

Δ2-cycloHepten-1-01, acetate of (MAN-
NICH and HANCU), A., i, 276.

Heptenyi alcohol. See Δβ-Hepten-5-ol
and Methylhexen-5-ols.

Heptiene. See ε-Methyl-Δβ3-hexadiene.

Heptioic acid, mercuric salt (BOIN-
WATER), A., i, 74.

See also αα3-Dimethylvaleric acid and
3-Methylhexioic acid.

Heptyl alcohol, chloro. See Diethyl-
β-chloroethylcarbinol.

Heptyl iodide. See β-Methylhexyl
iodide.

Δγ-Heptylene (ZELINSKY and PRSHE-
VALESKY), A., i, 845.

Heptylene glycol. See ββ-Dimethyl-
pentane-α7-diol.

Heptylene oxide. See α3-Dimethylal-
ene αβ-oxide.

Heptylideneacetone and its semiarc-
oxide-semiarcbazone (RUPE and HIN-
TERTHAL), A., i, 13.

Heptylideneacarbamidoxime (CONDUCHE,
A., i, 155.

Herring, chemical composition of the,
during the reproductive period (MI-
ROY), A., ii, 708.

Henlandite from Montrêsa, Sardinia
(PELACANI), A., ii, 864.

Hecna brasiliensis, latex of. See Rubber,
Para.

Hexacontane, molecular weight of
(STRUV), A., i, 749.

Δβy-Hexadiene and its dihydrobromide
and tetrabromide (REFI), A., i, 847;
(BRÜHL), A., ii, 1602.

cycloHexadiene (dihydrobenzene) deriva-
tives, optical behaviour of (AUWERS),
A., i, 520.

cycloHexadienes (ZELINSKY and GOR-
SKY), A., i, 619, 722; (BRÜHL), A.,
ii, 1003.

optical properties of, and their brom-
ides (ZELINSKY and GORSKY), A.,
i, 619.

substituted (CROSSLEY and RENOUF),
T., 629; P., 59.

Δ2ß-cycloHexadienecarboxylic acid, 1-
bromo-2-hydroxy- and 2-hydroxy-
ethyl esters (KÖTZ and GÜTZ), A., i,
174.

Hexahydroacetophenone. See cyclo-
Hexyl methyl ketone.

Hexahydrobenzoxylacetic acid, esters
and copper salts (WAHL and MEYER),
A., i, 890.

3-Hexahydrobenzoyl-6-cyclohexyl-2.4-
pyrone (WAHL and MEYER), A., i,
891.

Hexahydrobenzylmalonic acid, and its
ethyl ester (ZELINSKY), A., i, 864.

Hexahydrocarbazole, derivatives of
(BORSCHE, WITTE, and BOTHE), A.,
i, 365.

β-Hexahydrocarvacrol, carvacromenth-
one from (BRUNEL), A., i, 91.

α-Hexahydrofavanthren hydrate
(SCHOLL and NEVIVUS), A., i, 740.

Hexahydrofavanthrens, α- and β-
(SCHOLL and HORDERMANN), A., i,
697.

Hexahydro-p-tolualdehyde, preparation
of (HARDING, HOWARTH, and PER-
KIN), T., 1974.

Hexahydroriphenylcarbinol. See cyclo-
Hexyldiphenylcarbinol.

2:3:4:5:6'-Hexamethoxydiphenyl-6:2-
dicarboxylic acid and its methyl ester
(HERZIG and POLAK), A., i, 547.

α:2:4:5:2':5'-Hexamethoxy-β-phenoxy-
β-phenylisobutyric acid and its
methyl ester and silver salt (ENGELS,
PERKIN, and ROBINSON), T., 1158.

2:13'13' Hexamethyltriamino-n-9-di-
phenyldihydroanthracene (GUYOT and
PIGET), A., i, 570.

Hexamethyltriamidiphenylmethylcar-
binol. See Naphtho-blue.

3:4':4'-Hexamethyltriaminodiphenyl-
-toluidine (BIELECKI and KOLENIK),
A., i, 698.

Hexamethyltriaminodiphenyl-tolyl-
methanes and -xylylmethanes and
their oxidation products (BIELECKI
and KOLENIK), A., i, 698.
cycloHexanone, condensation of, with ethyl α-bromoisobutyrate (WALLACH and MALLISON), A., i, 406.
condensation of, with ethyl α-bromo-propionate (WALLACH and EVANS), A., i, 403.
cycloHexane, 2-bromo- (KÖTZ and GÖTZ), A., i, 174.
cycloHexane-α-naphthylhydrazones and α--, m-, and p-nitrophenylhydrazones (BORSCH, WITTE, and BOTHE), A., i, 366.
cycloHexanyl-ethyl alcohol (ZELINSKY), A., i, 727.
Hexaphenylethane, attempt to prepare (ANSCHUTZ), A., i, 331.
△133-Hexatriene di- and tetra-bromides, crystal form of (JAEGE), T., 521; P., 21.
cycloHexene oxonides, α- and β-, decomposition of (HARRIES and V. SPLAWA NEYMANN), A., i, 965.
△-cycloHexeneacetic acid and its nitrite (HARDING, HAWORTH, and PERKIN), T., 1956.
△-cycloHexeneacetic acid, α-cyano-, and its ethyl ester (HARDING, HAWORTH, and PERKIN), T., 1956.
cycloHexene-α-butryric acid and its ethyl ester and silver salt (WALLACH, CHURCHILL, and RENTSCHLER), A., i, 404.
cycloHexeneisobutyric acid (WALLACH and MALLISON), A., i, 406.
cycloHexene-ethane and its nitrosochloride, α-nitropyridine, and methoxyloxime (WALLACH and EVANS), A., i, 403.
cycloHexene-α-propionic acid and its ethyl ester (WALLACH and EVANS), A., i, 403.
and its silver salt and nitrite, and α-cyano-, methyl ester of (HARDING, HAWORTH, and PERKIN), T., 1961.
Hexene series, studies in the (ZELINSKY and PRSHEVALSKY), A., i, 845.
△-Hexen-8-ol and its acetate and chloride (REIF), A., i, 847; (BRÜHL), A., ii, 1002.
△-cycloHexen-1-ol, esters of (MANNICH and HÄNCU), A., i, 276.
△-cycloHexenone and its semicarbazone (KÖTZ and GÖTZ), A., i, 174.
Hexenyl alcohols. See Dimethylisoallylicarbinol, △-Hexen-8-ol, and γ-Methyl-1,2-penten-β-ol.
cycloHexenyl methyl ketone and its oxime and semicarbazone (WALLACH and EVANS), A., i, 403.
INDEX OF SUBJECTS.

§1-cycloHexyl methyl ketone and its semicarbazones (WALLACH, CHURCHILL, and KEITSCHEL), A., i, 405.

4-isooHexylsalicylic acid (MEEWER, i, 90).

Hexinoic acid. See Sorbic acid.

n-Hexoic acid, a-amino-. See Lecine.

β-iodo-γ-hydroxy-, lactone of (BOUGAULT), A., i, 537.

Hexoic acids, l- and d- (NEUBERG and REWALD), A., i, 310.

See also αα-Dimethylbutyric acid, α-Ethylbutyric acid, and β-Methylvaleric acid.

Hexophenone, α-amino-, and its additive salts (GABRIEL and COLMAN), A., i, 649.

isoHexylamine. See under the parent Substance.

d-isoHexyl-l-histidine, α-bromo-, and its methyl ester (FISCHER and CONF), A., i, 1005.

isoHexyl-α-methylisoserines, α-bromo-, α- and β-compounds of (KAY), A., i, 774.

d-isoHexyl-l-proline, α-bromo-, and α-hydroxy-, amide and lactone of (FISCHER and REIF), A., i, 1008.

d-isoHexyl-l-tyrosine, α-bromo- (ANDERHALDEN and HIRSZOWSKI), A., i, 888.

isoHexyl-d-valine, d-α-bromo- (FISCHER and SCHEIBLER), A., i, 598.

Hexyl alcohol, active, rotatory power of (CHARDIN), A., ii, 913.

Hexyl bromide, active, rotatory power of (CHARDIN), A., ii, 913.

cycloHexyl ether (IPATIEFF and PHILIPOFF), A., i, 842.

cycloHexylacetic acid, β-bromo- (HARDING, HAWORTH, and PERKIN), T., 1960.

cycloHexyl-2-acetic acid, 2-bromo-1-hydroxy-, lactone of (HARDING, HAWORTH, and PERKIN), T., 1963.

Hexylbenzene, active (α-phenyl-γ-methylpentane), rotatory power of (CHARDIN), A., ii, 913.

cycloHexylcarbinol and its acetate and iodoide (FAWORSKY and BORGMAN), A., i, 15.

cycloHexyl-p-dimethylaminophenylcarbinol (SCHMIDLIN and V. ESCHER), A., i, 164.

cycloHexylphenylcarbinol (SCHMIDLIN and V. ESCHER), A., i, 163.

n-Hexylene (ZELINSKY and PIRSCHIVALSKY), A., i, 845.

Hexylene. See also β-Methyl-αβ-amylene.

Hexylene azonide (HARRIES and HAEFFNER), A., i, 846.

B-cycloHexylethylamine, preparation of, and behaviour of, towards nitrous acid (WALLACH), A., i, 426.

cycloHexylglycollic acid (ZELINSKY and SCHWEDOFF), A., i, 864.

cycloHexylidenacetic acid (HARDING, HAWORTH, and PERKIN), T., 1961.

cycloHexyl methyl ketone and its p-nitrophenylhydrazone (WALLACH and EVANS), A., i, 404.

3-cycloHexylisooxazolone (WAHL and MEYER), A., i, 891.

cycloHexylpropionic acid and its amide (ZELINSKY), A., i, 864.

Hippocoprosterol (DORÉE and GARDNER), A., ii, 514.

Hippomelanin (Rona and RIESER), A., i, 1028.

Hippuric acid, limits of the formation of, in man (LEWINSKI), A., ii, 518.

produced in animals, parent substance of (VASILIUS), A., ii, 211.

scission of, by bacteria (SEO), A., ii, 518.

test for, in urine (DÉHN), A., ii, 907.

separation of, from urine (ROAF), A., i, 584.

Hippuric acid, p-hydroxy- (FISCHER), A., i, 892.

Hippurinitrile, 4-nitro-2-amino- 2-N-acetyl derivative of (BOGERT and KLÄBER), A., i, 468.

Hirudin, effect of, on blood-gases (BARCROFT and MINES), A., ii, 117.

Histidine, arginine, and lysine, amount of, in the hydrolytic products of various animal tissues (WAKEMAN), A., ii, 209.

colour reaction of (KNOOP), A., ii, 642.

derivatives (FISCHER and CONF), A., i, 1004.

Hofmann's reaction with amides and hydrazine derivatives of carbonic acid (DARATSKY), A., i, 106.

Holmium and erbium, separation of (HOFMANN and BURGER), A., ii, 189.

α-Homobetaine. See Trimethyl-α-propio-betaine.

Homo-olestranol (Power and TUTIN), T., 896; P., 117.

Homophthalic acid, esters (DIECKMANN and MEISEN), A., i, 894.

Homopiperonal and its oxime, semicarbazone, nitrile, and amine (SEMMLER and BARTTEL), A., i, 901.

Homopiperonyl alcohol (SEMMLER and BARTTEL), A., i, 902.

Homopiperonylic acid and its methyl ester (SEMMLER and BARTTEL), A., i, 901.

Homotanacetonedicarboxylic acids (SEMMLER) A., i, 92.
INDEX OF SUBJECTS.

Hydrate theory, the effect of one salt on the hydrating power of another salt present in the same solution (Jones and Stine), A., ii, 474.

Hydrates, formed by a number of electrolytes, approximate composition of the (Jones and Pearce), A., ii, 19, of fatty acids, according to measurements of the viscosity of their solutions (Tsakalotos), A., i, 498, 598.

Hydration values, determination of (Armstrong and Crothers), A., ii, 816.

Hydrotropyltropeine, bromo-, hydro-bromide of, and chloro-, and its hydro-chloride, picrate and platinichloride (Wolffenstein and Marmlock), A., i, 281.

Hydrazine, preparation of (Raschig), A., ii, 1029.

action of cyanogen bromide on (Pellizziari and Repetto), A., i, 65.

oxidation of (Browne and Shetterly), A., ii, 373.

action of nitrous esters on, in alkaline solution (Stollé), A., i, 917; (Thiele), A., i, 927; ii, 940.

influence of, on the intermediary metabolism of the dog (Underhill and Kleiner), A., ii, 214.

and nitroso-, cobaltinitorites of (Hofmann and Buchner), A., i, 876.

hydrate, action of, on diazoacetamide and on ethyl diazoacetate (Curtius, Darapsky, and Bookmühl), A., i, 144.

action of, on nitro-compounds (Curtius and Mayer), A., i, 53.

as-Hydrazines, secondary, action of, on carbamide (Millrath), A., i, 581, 1014.

as-sec.-Hydrazines, reactions of (Franzen and Schueermann), A., i, 293.

Hydrazines, aromatic, oxidation of, by metallic oxides, permanganates, and chromates (Chattaway), T., 270; P., 10.

conversion of, into diazonium salts (Chattaway), T., 852; P., 74.

Hydrazino-groups, replacement of hydroxyl groups by (Franzen and Eichler), A., i, 831.

2-Hydrazino-1:3:4-triazo1, 1-amino-5-thiol- (Stolle and Bowles), A., i, 475.

Hydrazo-compounds, electrolytic preparation of (Darmsitder), A., i, 301.

5-Hydrazodiethylphthalide (Bauer), A., i, 274.

Hydrazoic acid. See Azoinide.
Hydrazotartronic acid, methyl ester, preparation of (Curtiss and Tarnow斯基), A., i, 760.

Hydrazotoluene, transformation of, into toline (van Loon), A., i, 831.

Hydrazo-. See also Hydrazino-.

Hydrindene derivatives, formation of, from α-phenylenedicarbonitrile (Moore and Thorpe), T., 165; P., 12.

Hydrazotoluene, 8-imino-α-cyano-, and its phenylhydrazine derivative (Moore and Thorpe), T., 176; P., 12.

β-Hydrindone, preparation of (Moore and Thorpe), T., 186; P., 13.

action of bromine on (Creeth and Thorpe), T., 1507; P., 192.

β-Hydrindone, α-cyano-, and its phenylhydrazone, metallic salts, and O-benzoyl derivative (Moore and Thorpe), T., 175; P., 13.

formation of (Creeth and Thorpe), T., 1509.

Hydridic acid. See under Iodine.

Hydroanthracenes and their derivatives (Godchot), A., i, 16.

Hydroaromatic acids, conversion of, into their aldehydes (Merling), A., i, 653.

Hydroaromatic aldehydes, formation of, from their acids (Merling), A., i, 653.

Hydroaromatic compounds, study of (British Association Reports), A., i, 328.

transitions of, to aromatic compounds (Kötz and Götz), A., i, 173.

Hydrobilirubin, extra-intestinal origin of (Austin and Ordway), A., ii, 408.

Hydrobromic acid. See under Bromine.

Hydrocarbon, C₄H₉, and its derivatives, from cyclobutylidimethylcarbinol (Küner), A., i, 530, 865.

C₁₀H₈, from Philippine terpenes (Bacon), A., i, 815.

C₁₅H₂₄ (two), from Caryophyllene (deussen and Lewinsohn), A., i, 354.

C₁₉H₉, from the action of sodium alkyl on ethylbenzene (Schörgin), A., i, 886.

C₁₉H₂₉, from the action of magnesium methyl iodide on ethyl 1-methyl-Δ⁵-cyclopentene-2-carboxylate (Haworth and Perkin), T., 597.

C₁₉H₂₁₉, from methyl α-phenylethylaminylideneacetate and magnesium methyl iodide (Reimer and Reynolds), A., i, 989.

C₂₅H₄₉, from magnesium p-tritolylmethyl chloride and benzaldehyde (Schmidlin and Hodgson), A., i, 240.

Hydrocarbon equilibria, calculation of (V. Wartenburg), A., ii, 26, 676.

Hydrocarbons, formation of, by the interaction of metals of the aluminium group with organic haloids (Spencer and Wallace), T., 1827; P., 194.

formation of, by the interaction of alkyl haloids with magnesium (Spencer and Crewdson), T., 1821; P., 194.

lecture experiments on the preparation of (Spencer), A., i, 620.

two, in the unsaponifiable portion of chrysaldene oil (Menozzi and Moreschi), A., i, 241.

thermal behaviour of (Redgrove), A., ii, 758.

thermal decomposition of (Bone and Coward), T., 1197; P., 167.

dissociation of several, in the endimeter for measuring fire-damp (Gréhant), A., i, 493.

equilibrium of the hydrogenation of (Padoa and Farris), A., i, 255, 776.

oxidation of, by air in presence of phosphorus (Colson), A., i, 435.

contact oxidation of (Orloff), A., i, 520.

action of sulphur on (Capelle), A., i, 201; (Oechsner de Coninck), A., i, 750.

aromatic, relation between the absorption spectra and chemical constitution of (Baly and Tuck), T., 1902; P., 223.

of the benzene series, oxidation of (Law and Perkin), T., 1633; P., 195.

cyclic, with semicicular linkings, preparation of (Wallach, Churchill, Evans, Mallison, Mendelsohn, Bartholdy, and Rentschler), A., i, 402.

ethylenic, preparation of (Bouveau), A., i, 117.

with conjugate ethylene linkings, spectroscopic behaviour of (Brühl), A., ii, 1002.

hexacyclic, isomeric (Wallach), A., i, 425.

open-chain, halogen derivatives, crystal form of, with reference to the barlow-pope theory of structure (Jaeger), T., 517; P., 29.

quinonoid, preparation of (Staudinger), A., i, 410, 411; (Tschitschibabin), A., i, 872.

do the quinonidimethane series, preparation of (Tschitschibabin), A., i, 872.

saturated, action of nitric acid on (Nametkin), A., i, 329.
Hydrocarbons, saturated, containing two isopropyl groups, nitration of (Ko-nowallof), A., i, 241.

doubly unsaturated, addition of the higher oxides to (Wieland and Stenzel), A., i, 517

Hydrocarbons, dinitro, halogen derivatives of (Ponzio and Charrier), A., i, 521.

primary dinitro-, action of diazo-salts on (Ponzio), A., i, 482; (Ponzio and Charrier), A., i, 582.

See also Olefines, Paraffins, Terpenes, and Sesquiterpenes.

Hydrocellulose, cellulose, and oxycellulose, highly nitratred (Berl and Klaye), A., i, 504.

Hydrocelluloses (Schwalbe), A., i, 9.

Hydrochalkone, 2 '4'-dihydroxy-. See Phenyl phenylethyl ketone, op-dihydroxy-.

Hydrochloric acid. See under Chlorine.

Hydrocinnamic acid. See 3-Phenyl-propionic acid.

Hydrocoumarone and coumarone derivatives from 4:7-dimethylcoumarin (Fries and Fickewirth), A., i, 824.

Hydrocyanic acid. See under Cyanogen.

Hydrodi-b-naphthaphenazine, tetranitro- (Lemann and Grandmougin), A., i, 480.

Hydridphenazine, tetrachloro- and tetranitro- (Lemann and Grandmougin), A., i, 479.

Hydroditoluphenazines, o-, m-, and p- tetranitro- (Lemann and Grandmougin), A., i, 479.

Hydroergotinine. See Ergotoxine.

Hydrofluorides. See under Fluorine.

Hydrofluosilic acid. See under Fluorine.

Hydrogel and hydrosol, process of formation of (Lottermoser and Rothe), A., ii, 364.

Hydrogen, atomic weight of (Noyes), A., ii, 100, 367.

and chlorine, relative atomic weights of (Gray and Buft), P., 215.

new method of preparing pure (Mauricheau-Beaupré), A., ii, 829.

purification of, from arsenic (Reckleben and Lockemann), A., ii, 271.

change in the spectrum of, under the prolonged action of strong electric discharges (Rogovsky), A., ii, 335.

distribution of intensity in the spectra of the canal rays in (Stark and Stebbing), A., ii, 546.

electrochemical equivalent of (Lehfeldt), A., ii, 559.

Hydrogen, ionic conductivity of (Görke), A., ii, 150.

passage of, through a palladium septum, and the pressure it produces (Tsakalotos), P., 208.

direct union of, with carbon (Bone and Coward), T., 1975; P., 222.

slow combination of chlorine with, under the influence of heat (Sink), A., ii, 172.

and nitrogen, chemical action of radium emanation on (Cameron and Ramsay), T., 984; P., 192.

and oxygen, chemical action of radium emanation on (Cameron and Ramsay), T., 971; P., 132.

Hydrogen antimonide. See Antimony trihydride.

arsenide. See Arsenic trihydride.

bromide. See under Bromine.

chloride. See under Chlorine.

cyanide. See under Cyanogen.

iodide. See under Iodine.

nitride. See Azoinide.

peroxide, preparation of (Barnes and Shearer), A., ii, 345, 829; (Fischer and Ringel), A., ii, 370; (Kahlbaum), A., ii, 829.

formation of, by the silent electric discharge (Löhr), A., ii, 480.

production of, from persulphuric acid (Consorzium für Elektrochemische Industrie), A., ii, 1023.

ozone, and nitrogen peroxide, formation of, in reactions in air which develop high temperatures (Keiser and McMaster), A., ii, 223.

photographic action of (Saeland), A., ii, 789.

photographic capacity and supposed radioactivity of (O. and A. Dony-Hénault), A., ii, 647.

catalysis of, by iodine and iodine ions (Abel), A., ii, 939.

kinetics and catalysis of the reaction between a thiosulphate and (Abel), A., ii, 26.

pulsating catalysis of, by mercury (v. Antropoff), A., ii, 472.

catalytic decomposition of, by means of an electric current (Bredig and Wilke), A., ii, 679.

catalytic decomposition of, under high pressures of oxygen (Spear), A., ii, 370.

action of alternating currents of high frequency on the decomposition of, by colloidal platinum (Leebeeff), A., ii, 166.
INDEX OF SUBJECTS.

Hydrogen peroxide, decomposition of, by means of platinum foil compared with catalysis by colloidal platinum (Teletoff), A., ii, 95.

decomposition of, in presence of various substances (Filippi), A., ii, 271.

interaction of, with sulphides (Gazdar and Smiles), T., 1833; P., 216.

double compounds of, with organic compounds (Tanatar), A., i, 399.

test for, in presence of aldehydes (Molinari and Fenaroli), A., i, 849.

ozone, and nitrogen peroxide, detection of, in gaseous mixtures (Keiser and McMaster), A., ii, 222.

detection of, in milk (Feder), A., ii, 318; (Wilkinson and Peters), A., ii, 907, 1069.

phosphide, action of, on mercuric bromide or chloride (lemoults), A., ii, 35.

sulphide, heat of vaporisation of (Elliott and McIntosh), A., ii, 354.

absolute density of (Baume and Perrot), A., ii, 940.

action of, on alkaline solutions of zinc salts (McCay), A., ii, 431.

replacement of, in chemical analysis (Donath), A., ii, 730.

lowest oxides of (Fromm, Roessicke, and Gaupp), A., i, 969.

disulphide (Bloch and Höhn), A., ii, 579.

collection of (Bloch), A., ii, 580.

trisulphide (Bloch and Höhn) A., ii, 579; (Schenck and Falcke), A., ii, 762.

constitutions of (Bloch), A., ii, 580.

ersulphide, action of, on organic compounds (Brunner and Vittelmann), A., i, 900.

persulphides (Strecker), A., i, 386; (Bruni and Borro), A., ii, 102; (Bloch and Höhn), A., ii, 579; (Bloch), A., ii, 580.

Hydrogen, estimation of, in technical gas analysis (Hausen), A., ii, 425.

active, estimation of, in organic compounds (Zerewitinoff), A., i, 593.

and carbon, the Carrasco-Plancher method of estimating, in organic substances (Lenz), A., ii, 65.

Hydrogenase, proof, by means of the chromogram method, that, takes an active part in alcoholic fermentation (Grüß), A., i, 491.

Hydrogenation, equilibrium of (Padoa and Fabris), A., i, 255, 776.

Hydrogen electrode. See Electrode under Electrochemistry.

Hydrogen ions, derived from transference experiments with nitric acid, equivalent conductivity of the (Noyes and Kato), A., ii, 346.

Hydrogen ions, examination of the conception of, in catalysis, salt forma-
tion, and electrolytic conduction (lapworth), T., 2187; P., 275.

estimation of the concentration of, by indicators (Michaelis and Rona), A., ii, 571.

"Hydrogen number," the, as a means of determining unsaturated organic compounds in a manner similar to the iodine numbers of Hübl and Wys (Fokin), A., ii, 637.

Hydrolation, hydronation, and hydrolysis as determinants of the properties of aqueous solutions (Armstrong), A., ii, 814.

Hydrology, isolation of traces of mineral substances from saline mixtures in (Meilhère), A., ii, 62.

Hydrolysis. See under Affinity, chemical.

Hydronation, hydrolation, and hydrolys as determinants of the properties of aqueous solutions (Armstrong), A., ii, 814.

Hydropinenealdehyde and its oxime and semicarbazone (Houben and Doeschel), A., i, 27.

Hydropiperic acid, estimation of, volumetrically (Bougault), A., i, 983.

Hydropiperin and isoHydropiperin, action of thionyl chloride on (Barger and Ewins), T., 735; P., 60.

Hydrosol and hydrogel, process of formation of (Lottermoser and Roth), A., ii, 364.

Hydrosols, freezing of (Bobertag, Feist, and Fischer), A., ii, 1024.

See also Colloidal solutions.

Hydrotphymine, 5-nitro-4-hydroxy-α- and β- forms (Johnson), A., i, 692, 739.

Hydroureael, 5-chloro-5-bromo-4-hydroxy-, 5,5-dichloro4-hydroxy-, and 5-chloro5-nitro-4-hydroxy- (Johnson), A., i, 739.

Hydroureael-4-acetic acid, 5-dibromo-4-hydroxy- (Wheeler and Liddle), A., i, 694.

Hydroxides. See Metallic hydroxides and Perhydroxide bases.
INDEX OF SUBJECTS.

Hydroxy-acid, C_{10}H_{10}O_{3}, and its salts, from pinene (Henderson and Heilbron), T., 289; P., 81.

C_{12}H_{10}O_{3}, from turmeric oil (Ruthe), A., i, 95.

Hydroxy-acids, aromatic, and their esters, rule in benzyolation of (Lasar-Cohn and Lównenstein), A., i, 984.

organic, formation of salts and complex salts of (Ley and Erlér), A., i, 177; (Obermiller), A., i, 634; (Thiel), A., i, 791.

α-Hydroxy-acids, transformation of, into aldehydes (Guerbet), A., i, 123.

Hydroxyaldehydes, aromatic, preparation of (Dreyfus), A., i, 654.

β-Hydroxyaldehydes, aromatic, preparation of (WeiL), A., i, 800.

α-Hydroxycarboxylic acids, action of heat on (Le Sueur), T., 716; P., 70.

Hydroxy-compounds, aromatic, action of sulphites on (Bucherer and Seyde), A., i, 455.

See also under the parent Substance.

α-Hydroxy-α-dialkyl ketones (Blaise and Herman), A., i, 318.

Hydroxy-fatty acids, ammonium salts, oxidation of, by hydrogen peroxide (Dakin), A., i, 75.

Hydroxy-ketones, aromatic, hydrazones of (Torrey and Kipper), A., i, 460.

Hydroxylamine and its salts (Ebler and Schott), A., ii, 1029.

and its hydrochloride, reaction of, with carboxyl compounds (Acree), A., ii, 169.

electrolytic reduction of, at copper cathodes (Tafel and Hahl), A., ii, 174; (Tafel), A., ii, 582; (Rothmund and Flaschner), A., ii, 583.

action of, on ketones of the type, CHR:CH:CH:CO-R (Ciusa and Tenzi), A., i, 762.

action of, on santonin (Francesconi and Cusmano), A., i, 272.

behaviour of, in the organism (Ciusa and Luzzatto), A., ii, 876.

action of, on fats (Morelli), A., i, 758.

Hydroxy groups, replacement of, by hydrazino-groups (Franzen and Eichler), A., i, 831.

phenolic, estimation of (Herzog and Hancu), A., ii, 927.

Hygric acids, hydroxy-, isomeric (hydroxy-N-methylprolines) (Leuchs and Felser), A., i, 510.

Hygroscopy, importance of, in general analysis (Reichard), A., ii, 891.

Hypernephromas, malignant, fats and lipoids of (Wells), A., ii, 411.

Hypnotic action of the valeric acid group (Van der Eekhout), A., ii, 55.

Hypoidous acid. See under Iodine.

Hypotirnous acid. See under Nitrogen.

Hypophosphoric acid. See under Phosphorus.

Hypophosphorous acid. See under Phosphorus.

Hypsephitates. See under Sulphur.

Hypothermolysin (Olivli), A., ii, 49.

Hypovannid acid. See under Vanadium.

Hypoxanthine and its aurichloride (Haiser and Wenzel), A., i, 562.

Hyssop oil (Schiimmel & Co.), A., i, 667.

I.

Ice, density and latent heat of fusion of, and the molecular depression of the freezing point in aqueous solutions (Roth), A., ii, 757.

Idocerase from Sardinia (Pelloux; Rimatori), A., ii, 863.

1-Idose, isolation of (Blanksma and Alberda van Ekenstein), A., i, 952.

transformation of, into 1-sorbose (Alberda van Ekenstein and Blanksma), A., i, 136.

Ignition temperature. See under Thermochemistry.

Illicyl alcohol and α-amyrin, identity of (Jungfleisch and Leroux), A., i, 1000.

Illuminating gas. See under Gas.

Ilmenorutile and its relation to strüverite (Prior and Zambonini), A., ii, 398.

Ilyvite from Shasta Co., California (Prescott), A., ii, 705.

Imide chlorides, action of potassium thiocyanate on (Johnson and Storey), A., i, 837.

Imides of the aromatic sulphonylic acids, preparation of (Haga), A., i, 870; (Suzuki), A., i, 871.

Iminazole ring, resolution of, in amarine and anisine (Fischer and Prause), A., i, 219.

series, tautomerism in the (Gabieli), A., i, 573.

Iminazoles, formation of (Meldola and Hay), T., 1659; P., 197.

Iminazolones. See Glyoxalones.

β-Iminazolylproponic acid and α-chloro- (Windaus and Vogt), A., i, 694.

Imino-acids, synthesis of (Stadnikoff), A., i, 251.

Imino-compounds, formation and reactions of (Moore and Thorpe), T., 165; P., 12; (Best and Thorpe), P., 288.
INDEX OF SUBJECTS.

Iminodiacetic acid and its derivatives (Jongkees), A., i, 959.
β-naphthalenesulphonyl derivative and its barium salt (Bergell and Feigl), A., i, 396.

Iminodiactimide. See 2,6-Diketopiperazine.

Imino-esters, catalysis of (Derby), A., i, 419; (Stieglitz), A., ii, 167, 168; (McCracken), A., ii, 572; (Schlesinger), A., ii, 680.

Imino-esters, chloro-, 

isostereoisomerism of (Stieglitz), A., i, 726.

Iminosyndrine and 4-nitroso-

(Michaelis, Mielecke, and Lutze), A., ii, 62.

Imperatoria Ostruthium, constituents of the rhizome of (Herzog), A., ii, 978.

Inanition, metabolism of calcium, magnesium, and phosphorus during (Wellmann), A., ii, 306.

Indazole and its silver and mercuric derivatives (Jacobson and Huber), A., i, 299.

derivatives, formation of, from o-methylated anilines (Jacobson and Huber), A., i, 298.

Indene, preparation of pure (Boes), A., i, 410.

Indene-3-carboxylic acid, 2-amino-, and its ethyl ester and amide, and their hydrochlorides (Moore and Thorpe), T., 183; P., 13.

2:3-Indenobenzopyranol(1:4) and 7-hydroxy-, and their salts (Perkin and Robinson), T., 1099.

Indiarubber. See Caoutchouc.

Indican, detection of, in urine (Salkowski), A., ii, 999.

Indicator, metselil yellow as a selective (Linder), A., ii, 627.

Indicators, theory of (Acree), A., i, 423, 652; (Stieglitz), A., i, 652; (Acree and Slagle), A., i, 653.

Establishment of the isomerism theory of, in the case of methyl-orange and helianthin (Hantzsch and Hilscher), A., i, 469.

constitution of, used in acidimetry (Hewitt), A., ii, 269.

for the titration of cinchona bases (Rupp and Seevers), A., ii, 259.

addition of indigo in titrations with methyl- or ethyl-orange (Luther), A., ii, 62.

Indigofera arrecta and I. sumatranana, analysis of the leaves of (Gaunt, Thomas, and Bloxam), A., ii, 76.

Indigo, analysis of (Gaunt, Thomas, and Bloxam), A., ii, 76.

Indigoid dyes (Friedländer), A., i, 371, 673; (Bezdzik and Friedländer), A., i, 673; (Friedländer and Schuloff), A., i, 674.

behaviour of, towards alkalis (Friedländer), A., i, 372.

Indigo-red series, thio-, preparation of colouring matters of the (Farwerke vorm. Meister, Lucts, & Brüning), A., i, 987.

Indigotin, preparation of (Lilienfeld), A., i, 797.

stereochemistry of (Falk and Nelson), A., i, 107.

electrolytic reduction of (Chumat), A., i, 107.

and α-, m-, and p-dichloro-, colours of, in various solutions (Schwalbe and Jochheim), A., i, 1019.

behaviour of, towards alkalis (Friedländer), A., i, 372.

reaction of, with potassium permanganate (Miller and Smirnoff), A., i, 468.

some unsymmetrical analogues of (Gros), A., i, 1011.

estimation of, in indigo-yielding plants (Bergtheil and Briggs), A., ii, 75.

Indigotin, tri- and tetro-bromo-, preparation of (Gesellschaft für Chemische Industrie in Basel), A., i, 468.

chloro-, and its leno-compound, preparation of stable (Gesellschaft für Chemische Industrie in Basel), A., i, 695.

α-, m-, and p-chloro-, colours of, in various solutions (Schwalbe and Jochheim), A., i, 1019.

chlorobromine, preparation of (Gesellschaft für Chemische Industrie in Basel), A., i, 1019.

tri-, tetro-, and hexa-halogenated derivatives, preparation of (Gesellschaft für Chemische Industrie in Basel), A., i, 798.

Indigotin group (Wieland and Gmelin), A., i, 1013.

Indigotinsulphonic acids, halogen (Schwalbe and Jochheim), A., i, 1019.

Indium, interaction of, with organic halogen compounds (Spencer and Wallace), T., 1832; P., 194.

Indium perchlorate, iodate, selenate, and cacoxen selenate (Mathers and Schliekemberg), A., ii, 386.

silicotungstates (Wyrouboff), A., ii, 386.

Indium, separation of iron from (Mathers), A., ii, 434.
Indole in flowers (WEEHUIZEN), A., ii, 1065.
regular occurrence of, in urine (JAFFÉ), A., ii, 1057.
urinary pigments derived from (BENEDICENTI), A., ii, 1057.
derivatives (HINSBERG), A., i, 453.
detection of, in pus (PORCHER), A., ii, 769.
estimation of, in feces (V. MORACZEW-SKI), A., ii, 441; (GORTER and DE GRAAFF), A., ii, 783.
Indoles (ANGELI and MORELLI), A., i, 828.
electrolytic reduction of the (CARRASCO), A., i, 912.
reactions of (ANGELI and MARCHETTI), A., i, 207.
Indoles, nitroso-, structure of (ANGELI and MORELLI), A., i, 828.
Indole-acetic acid as the chromogen of urorosein (HERTER), A., ii, 410.
Indolinones, formation of (LIEBER), A., i, 681.
Indolyldiacetic acid, α-amino-, N-benzoyl derivative of, and its reduction (ELLINGO and FLAMAND), A., i, 378.
Indophenol, C₉H₄O₃N₂S, from p-toluenesulphonyl-N-α-phthylamine and p-aminophenol (CHEMISCHE FABRIK GRIESEHIM-ELEKTRON), A., i, 209.
Indophenol, sodium salt (CASSELLA & CO.), A., i, 416.
Indoxazin (CONDUCHÉ), A., i, 154.
Indoxyl and its derivatives, preparation of (LILJENFELD), A., i, 797.
and its homologues and derivatives, preparation of (BADISCHÉ ANILIN-& SODA-FABRIK; LILJENFELD), A., i, 371.
urinary, symptomatic significance of (PORCHER), A., ii, 769.
1-Indoxylbenzene, 3- and 4-hydroxy- and 3:4-dihydroxy-, and their sulphonic acids (FRIEDLÄNDER and SCHULOFF), A., i, 674.
Indoxylcarboxylic acid, thio-. See (1)-Thionaphthen-2-carboxylic acid, 3-hydroxy-.
Indoxylthionaphthenone (2-thionaphthen-2-indole-indigotin) (FRIEDLÄNDER), A., i, 372.
Indoxyl-2- and -3-thionaphthen-3- and -2-ones, 3'- and 2'- (BEZDZIK and FRIEDLÄNDER), A., i, 673.
Induline, explanation of the formation of (OSTROGOVICH and SILBERMANN), A., i, 373.
Indulines from aniline (BACOVESCÜ), A., i, 825.
Infant’s urine. See Urine.
Intramolecular, rearrangement in inactive substances, polarimetric study of (Patterson and McMillan), T., 1041; P., 135.
effected by fusion with potassium hydroxide (Blanksma; Tymstra), A., i, 262.
Invertase of the date (Vinson), A., ii, 418, 724.
from yeast, adsorption affinity of (Michaelis), A., i, 235.
Invert sugar. See Sugar, invert.
Iodide and Iodates. See under Iodine.
Iodide of starch, nature of (Katayama), A., i, 9; (Padoa), A., i, 249.
Iodides. See under Iodine and Polyiodides.
Iodination, studies in (Körner and Belasio), A., i, 778.
Iodine, new polymorphous form of (Kurhatoff), A., ii, 31.
electrolytic conductivity of, in nitrobenzene solution (Brunner), A., ii, 149.
relation between current and potential difference in solutions of, in potassium iodide (Brunner), A., ii, 754.
solubility of, in water (Hartley and Campbell), T., 741; P., 58.
action of, on some elements in vacuum (Guichard), A., ii, 31.
reaction of, with phosphorous acid (Steele), T., 2203; P., 193.
liberation of, from hydriodic acid by certain halogenated malonyl derivatives (Whiteley), P., 288.
comparative investigations on the elimination of, after administration of potassium iodide and salolin (Bächl), A., ii, 521; (Abderhalden and Kautzsch), A., ii, 611.
and selenium (Pellini and Pedrina), A., ii, 833.
and sulphur, existence of compounds of (Smith and Carson), A., ii, 32; (Ephraim), A., ii, 581.
Hydriodic acid (hydrogen iodide), photochemical oxidation of, by oxygen (Plotnikoff), A., ii, 790.
decomposition of, in light (Bodenstein), A., ii, 172.
influence of radium on the decomposition of (Creighten and Mackerzie), A., ii, 450.
influence of iron compounds and of peroxydases on the catalysis of, by hydrogen peroxide (Wolff and de Stoeklin), A., i, 746.

Iodine:
Hydriodic acid, liquid, heat of vaporisation of (Elliott and McIntosh), A., ii, 354.
Iodides, new type of combination of, with sulphur (Auger), A., i, 241.
Iodic acid, study of the oxidation phenomena produced by (Baubigny), A., ii, 577.
and bromic acid, estimation of, by means of thiosulphuric acid (Casolari), A., ii, 222.
periodates, bromates, and chlorates, estimation of, by means of formaldehyde, silver nitrate, and potassium persulphate (Brunner and Mellet), A., ii, 222.
Hypiodious acid, action of nascent, on unsaturated acids (Bougault), A., i, 179, 269, 537, 791, 983.
Iodine and chlorine, estimation of, in "erythrosine" (Jean), A., ii, 129.
bromine, and chlorine, separation of, by means of hydrogen peroxide in acid solution (Jannasch), A., ii, 730.
See also Halogens.
Iodo-. See also under the parent Substance.
"Iodoargyrum" (Nardelli), A., ii, 715.
Iodo-fatty acids, higher, preparation of esters of (Färbenfabriken Vorm. F. Bayer & Co.), A., i, 310.
Iodoform-sulphur (Auger), A., i, 241.
Iodogorgonic acid. See Tyrosine, 2:5-diiodo-.
Iodohydrins, aromatic, mechanism of the transposition of phenyl in (Tiffenau), A., i, 165, 166; (Tiffenau and Daudel), A., i, 972.
Iodolactones (Bougault), A., i, 537.
Ionic concentrations, experiments, and mobility, Ionisation, and Ions. See under Electrochemistry.
Ionised gases. See under Gases.
Ionium (Mackwald and Kemptman), A., ii, 144; (Boltwood), A., ii, 455.
3-Ionone hydrate, preparation of (Coulin), A., i, 1000.
Ipomea purpurea, chemical examination of (Power and Rogerson), A., ii, 725.
Ipuranol and its diacetyl derivative from olive bark (Power and Tutin), T., 907; P., 118.
Ipuranol and its acetyl derivative and Ipurolic acid and its esters and salts (Power and Rogerson), A., ii, 725.
Iridium, wave-length tables of the arc and spark spectra of (British Association Reports), A., ii, 334.
Iridium salts, complex (Gialdini), A., i, 3.
Iridium chlorides, compounds of, with alkalies (Delépine), A., ii, 702; (Vézés), A., ii, 703.

oxides (Wöhler and Witzmann), A., ii, 300.

solid solutions in the dissociation of (Wöhler and Witzmann), A., ii, 301.

Iridium crucibles, use of, in chemical operations (Crookes), A., ii, 702.

Irido-oxalates (Gialdini), A., i, 3.

Iron, crystallised, from a foundry at Teschen, Austria (Cornu), A., ii, 949.
electrolytic, preparation of (Amberg), A., ii, 598.
metallic, constitution of (Tilden), T., 1862.

flame spectra of (Hemsalech and de Watteville), A., ii, 336, 445.
spectrum of, in a hydrogen flame (Hemsalech and de Watteville), A., ii, 547.
spectrum of, observed in the oxyhydrogen blowpipe flame (Hemsalech and de Watteville), A., ii, 547.
decarburisation of (Wüst), A., ii, 286.

passivity of (Fredenhagen), A., ii, 679.
cobalt, and nickel, experiments on the passivity of (Byers), A., ii, 1026.
rusting of (Tilden), T., 1356; P., 169; (Friend), A., ii, 698.
corrosion of, by water and water solutions (Heyn and Bauer), A., ii, 849.
rust, composition of (Tilden), T., 1362; P., 189.
solubility of graphite in (Charpy), A., ii, 110; (Benedicks), A., ii, 275.
as oxygen carrier (Cervello), A., i, 1027.
of the liver (Scaffidi), A., ii, 210.
percentage of, in fats, lipoids, and waxes (Glikin), A., ii, 407.

Iron alloys with aluminium (Gwyer), A., ii, 285.

with carbon (Charpy), A., ii, 697.
specific heat of (Oberhoff and Meuthen), A., ii, 886.
influence of phosphorus on (Wüst), A., ii, 287.

with carbon and phosphorus (Goerens and Dobbelstein), A., ii, 1042.
with carbon and silicon (Gontermann), A., ii, 851.
with copper (Sahmen), A., ii, 186.
with phosphorus (Gercke), A., ii, 1041.

Iron alloys with vanadium (Vogel and Tammann), A., ii, 502.

See also Ferro-alloys, Ferrochrome, Ferro-silicon, and Ferro-vanadium.

Iron compounds, hysteresis of certain (Berndt), A., ii, 1013.
colloidal, as peroxide-diastases (Wolfe), A., i, 137, 490; ii, 573, 1022;
(Wolff and de Stoëflin), A., i, 746.

Iron salts, reducing and oxidising power of ( Müller and Kapeller), A., ii, 192.

complex, in which the iron is masked (Pascal), A., ii, 193.

and copper salts in presence of acids and alkalis (Frischer), A., ii, 947.

Iron antimonides (Kurnakov and Constantinoff), A., ii, 390.
carbide, formation of (Pring), T., 2105; P., 241.
carbides (Upton), A., ii, 1042.
hydroxide, heterogeneous colloid (Sziglár), A., ii, 197.
oxide, spent, estimation of naphthalene in (Gair), A., ii, 135.
bisulphides, utilisation of native (Schröder), A., ii, 500.
barium silicate. See Taramellite, sulphates, anhydrous, thermal dissociation of the (Keppeler and D'Ans), A., ii, 289; (L. Wöhler, Plüdemann, and P. Wöhler), A., 290, 581.
sulphide (Malatti), A., ii, 192.
and aluminium sulphide, probable existence of a compound of (Ditz), A., ii, 111.
sulphides, decomposition of, by aluminium (Ditz), A., ii, 111.

Ferric salts, complex, relation between magnetic and chemical properties of (Pascal), A., ii, 756, 927.
oxidations effected by (Bongiovanni), A., i, 770.
ammonio-salts, new series of, in which the iron is masked (Pascal), A., ii, 193.
chloride, structure of (Jufereff), A., ii, 698.

and ferrous chloride, conductivity of solutions of (Jufereff), A., ii, 698.
hydrolysis of (Malfitano and Michel), A., ii, 111.
hydrolysis of, effect of the valency of the negative ions on the (Malfitano and Michel), A., ii, 288.
influence of neutral salts on the hydrolysis of (Malfitano and Michel), A., ii, 1042.
Iron:—

Ferric chloride, conditions of equilibrium in the systems, potassium ferrocyanide, water, and (Volschin), A., ii, 468.
reaction between potassium thio-
cyanate and (Bongiovanni), A., i, 770, 859.
compounds of, with alkaloidal salts (Scholtz), A., i, 202.
chlorides (Cameron and Robinson), A., ii, 112.
hydroxide, nature of the pseudo-
solutions of (Giolitti), A., ii, 950.
hydroxylamite (Ebler and Schott), A., ii, 1031.
oxide, preparation of pure (Brandt), A., ii, 899.
electrolytic inactivity of (Peters), A., ii, 387.
dissociation pressures of (WAL-
den), A., ii, 852.
different colours of, an effect of the size of the grains (Wöhler and Condrea), A., ii, 287.
sulphates (Cameron and Robinson), A., ii, 112.

Ferrous salts, effect of ferric salts on the rate of oxidation of, and on the catalytic action of (Green), A., ii, 824.
oxide, estimation of, in rock analyses (Mauzelius), A., ii, 538.
oxide hydrate, natural (Hart), A., ii, 861.

Iron organic compounds:—

Iron organic salts (Rosenthaler and Siebeck), A., i, 246.
Ferrous ferrocyanide, colloidal, oxyd-
asic phenomena produced by (Wolff), A., i, 490; ii, 1022.
Iron and manganese minerals from the crystalline schists of Brosteni, Rou-
mania (Butureanu), A., ii, 955.
Iron ore from Bohemia, a remarkable (Zeck and Döring), A., ii, 397.
Iron ores, estimation of arsenic in (Güedras), A., ii, 984.
separation of alumina and silica in (Timby), A., ii, 533.

Cast iron, identity of graphite and “temper” graphiccarbon in (Chaply), A., ii, 37.
estimation of phosphorus in (Ches-
neau), A., ii, 427.

Cast-irons containing manganese, con-
titution of (Gullet), A., ii, 192.

Fig-iron, estimation of carbon in (Orthey), A., ii, 131.

Steel process, Thomas basic (Wüst and Laval), A., ii, 851.

Iron:—

Steel, loss of carbon during solution of, in potassium cupric chloride (Moore and Bain), A., ii, 899.
direct combustion of, for carbon and sulphur (Isham and Aumer), A., ii, 898.
apparatus for the estimation of carbide in (Mars), A., ii, 429.
estimation of carbon in (Orthey), A., ii, 131.
estimation of carbon in, by means of an electric furnace (Johnson), A., ii, 630.
estimation of chromium and nickel in (Campbell and Arthur), A., ii, 779.
estimation of chromium, molybd-
enum, nickel, and vanadium in (Blair), A., ii, 900.
estimation of chromium and tungsten in (Höffrichsen and Wolter), A., ii, 900.
volumetric estimation of manganese in (Sacerdoti), A., ii, 228; (Raymond), A., ii, 323.
estimation of phosphorus in (Ches-
neau), A., ii, 427; (Missen), A., ii, 732.
estimation of sulphur in (Jaboulay), A., ii, 223; (Orthey), A., ii, 731.
apparatus for the estimation of sulphur in (Raymond), A., ii, 628.
estimation of tungsten in, containing chromium (V. Knorre), A., ii, 779.
estimation of vanadium in (Camp-
bell and Woodhams), A., ii, 901.

Steels, gases occluded in (Belloc), A., ii, 108.
containing phosphorus (de Kry-
loff), A., ii, 698.
See also Nickel steel.

Iron (in general) detection, estimation, and separation:—
precipitation of, by ammonia in presence of tartaric acid (Strecker), A., ii, 71.
and copper, detection of (Delépine), A., ii, 633.
estimation of, by permanganate after reduction with titanous sulphate (Newton), A., ii, 538.
estimation of ferrous (Knight), A., ii, 323.
estimation of ferric (Bollenbach), A., ii, 229.
alumina, and phosphoric acid, estimation of, in presence of each other (Cooksey), A., ii, 987.
Iron (in general) detection, estimation, and separation:—
and chromium, volumetric estimation of, by means of titanic chloride (JATAR), A., ii, 778.
and vanadium, estimation of, in presence of each other (EDGAR), A., ii, 736.
apparatus for the estimation of carbide in (MARS), A., ii, 429.
estimation of carbon in (DE KONINCK and V. WINIARter), A., ii, 320.
apparatus for the estimation of carbon in (WIDEMANN), A., ii, 984; (GRZESCHIK), A., ii, 1071.
volumetric estimation of manganese in (RAYMOND), A., ii, 323.
estimation of phosphorus in (CRESNEAU), A., ii, 427.
estimation of sulphur in (JABOUlAY), A., ii, 223; (ORTHEY), A., ii, 731.
apparatus for the estimation of sulphur in (RAYMOND), A., ii, 628.
estimation of vanadium in (CAMPBELL and WOoDHAms), A., ii, 901.
colorimetric method for the estimation of small percentages of, in copper alloys (GREGORY), T., 93.
and vanadium, simultaneous volumetric estimation of, in ferro-vanadium (WARyNSki and MDIVANi), A., ii, 786.

pure ferric oxide as a standard substance for the estimation of, in hydrochloric acid solution (BRANDT), A., ii, 899.
volumetric estimation of, in ferric compounds (Muir), A., ii, 228.
estimation of, in reduced iron (FREichs), A., ii, 538.
separation of, from cobalt and nickel (LASBY), A., ii, 988.
separation of, from indium (MATHERS), A., ii, 434.
separation of, from manganese (MOORE and MILLER), A., ii, 434.
separation of, from thorium, titanium, and zirconium from (DITTRICH and FREUND), A., ii, 135.

Iron group, determination of the melting points of elements of the, by a new radiation method (BURGESS), A., ii, 41.

Iron and aluminium groups, qualitative analysis of the (NOYES, BRAY, and SPEAR), A., ii, 538.

Iron oxide contact process (KEPPELER, D'ANS, SUNDuell, and KAISER), A., ii, 482.

Isatin and its methyl derivative, preparation of (BAUER), A., i, 695.

Isatin, action of ethylamine on (HASLINGER), A., i, 454.

Isatinethyline, 5:7-dibromo- (HASLinger), A., i, 454.

α-Isatoxime (WIELAND and GmElIN), A., i, 1013.

Isomeric change, action of carboxyl chloride as an agent for arresting (LORRY and MAcSON), T., 119.
rearrangement (FAWORSKY and BORG-MANN), A., i, 15.

Isomeries, reciprocal transformation of, under the influence of chemical induction (TANATAR), A., i, 760.
structural, formal types of (LAAR), A., i, 749.

Isomerism, dynamic. See under Affinity, chemical.
structural (MARINO), A., ii, 833.

Isomorphism (GOSNLER), A., ii, 396.

Isomorphous substances and their mixtures, specific heats and heats of fusion of (BOGOJAWLESNSKY and WINGRADOFF), A., ii, 806.

J.

Jateorrhizine and its derivatives from calumba root (FEIST), A., i, 101.

Jecorin and other lecithin-like substances from the liver of the horse (BASKOFF), A., i, 1029.

Jeffropinic acids, α- and β-, and α- and β-Jeffropinic acids (TSCHIRCH and LEUCHTENBERGER), A., i, 197.

Jet, origin of (SPIELMANN), A., ii, 505.

K.

Kaersutite from Linoa and Greenland (WASHINGTON and WRIGHT), A., ii, 563.

“Kalkstickstoff.” See Manurial experiments.

Kaolin, formation of (HÄHNEL), A., ii, 956.

Katabolism, protein, action of hydrocyanic acid on (LOEwY, WOLF, and ÖSTERBERG), A., ii, 312.

Kayana-abura. See Terryra nucifera, oil of.

Keratin, state of combination of sulphur in the molecule of (BAUSCH), A., i, 710.

Keratins, various, glutamic acid in (ABDERHALDEN and FUCHS), A., i, 1029.

Ketchup, detection and estimation of benzoic acid in (REED), A., ii, 74.
estimation of benzoic acid in (LA WALL and BRADSHAW), A., ii, 438.

Keten (STAUDINGER and KLEVER), A., i, 246, 394; (WILSMORE and STEWART), A., i, 313.
2-Keto-1-methylidihydro-1'-2'-naphthoquinoxaline (LANGE), A., i, 839.

4-Keto-2-methyl-1:4-dihydroquinoline and its additive salts (HELLER and SOURLIS), A., i, 913.

2-Keto-1-methyltetraydroxanaphthalene, chloro-derivatives (FRIESE and HEMPELMANN), A., i, 730.
Ketones, reaction of, with diphenylmethanidedimethylhydrazine (V. Braun), A., i, 790.

action of mercuric iodide on, in alkaline solution (Marsh and Struthers), P., 266.

action of a mixture of mercury diethyl and sodium on (Schöningen), A., i, 881.

condensation of, with p-phenylene diamine, β-naphthylamine, and β-naphthylhydrazine (Rothefuss), A., i, 52.

condensation of, with ethyl phenylpropionate (Rüemann), T., 431; P., 52.

action of alcoholic potassium hydroxide on (Montagne), A., i, 988.

action of sodamide on (Haller and Bauer), A., i, 987.

action of sodium and alkyl haloids on (Schöningen), A., i, 866.

containing the group, CH₂CO-CH₃, condensation of, with esters in presence of sodium ethoxide (Clarke, Lapworth, and Wechsel, T., 30.

of the type, CH₂CH₂CH₃CO-R, action of hydroxylamine on (Crusa and Terni), A., i, 762.

naturally occurring aliphatic, synthesis of certain, and their possible mode of formation in the organism (Dakin), A., i, 134.

aromatic unsaturated, coloured hydrohalides of (Francesconi and Casamano), A., i, 801.

cyclic, new (Blanc), A., i, 654.

synthesis by means of the carboxylic esters of (Kötzt, Bieber, Hesse, and Schwartz), A., i, 24.

tautomerism of (Mannich and Hánku), A., i, 275.

condensation of, with aromatic aldehydes (Wallach, Mallison, and Martius), A., i, 424.

reaction of, with diphenylmethanidedimethylhydrazine (V. Braun), A., i, 737.

fatty, melting points of the p-nitrophenylhydrazones of, and their identification (Dakin), A., ii, 234.

hydroaromatic (Crossley and Gil-ling, P., 150, 281.

β-unsaturated, reduction of (Skita, Ardan, and Krauss), A., i, 855.

See also β-Acetoxycarboxymethylketones, Amino-ketones, β-Hydroxy-a-dialkyl ketones, Hydroxy-ketones, and Triketone.

Ketones, thio-derivatives of (Fromm, Lambricht, and McKee), A., i, 989.

Ketonic acid, C₆H₅O₂, and its semicarbazone, from 1-methyldecyclo-1:2:3-A'cyano-1-oxo-3-one (Semmler and Bartelt), A., i, 355.

C₆H₅O₃, and its semicarbazone from the diketone from santene (Semmler), A., i, 38.

C₆H₅O₃, and its semicarbazone, from the oxidation of apiophene (Bouveault and Levallois), A., i, 193, 195.

C₁₃H₂₀O₇, and C₁₃H₁₀O₇, and their phenylhydrazones, from santonin (Angeli and Marino), A., i, 543.

C₆H₅O₇, and its oxime, from the reduction of the acid, C₆H₅O₇N₃ (Winds nurturing A., i, 728.

C₈H₁₄O₁₃, and its oxime and potassium salt, from cholestenone (Dörée and Gardner), T., 1330; P., 173.

Ketonic acids, dibasic (Blaise and Gault), A., i, 713.

napthethresorecinol as a reagent for (Mandel and Neuberg), A., ii, 993.

Keto-Ketonic acids, determination of the constitution of isomeric derivitives of (Meyer), A., i, 28.

Ketonic and enolic compounds, behaviour of, with diazo-compounds (Tingle and Williams), A., i, 126.

the ammonia reaction for distinguishing between (Michael and Hibbert), A., i, 78.

tertiary amines as reagents for distinguishing between (Michael and Smith), A., i, 943.

acetyl chloride and acetic anhydride as reagents for distinguishing between (Michael and Murphy), A., i, 949.

β-Ketonic esters, new synthesis of (Zeltner), A., i, 243, 759; (Stolle), A., i, 310.

Keto-2-phenylbenzotriazine, m-cyanoamino- (Pierron), A., i, 925.

Keto-2-phenylidihydrobenzotriazine, m-cyanoamino- (Pierron), A., i, 926.

4-Keto-2-phenylimino-terahydrothio-phen-3-dicarboxylic acid, ethyl ester, and its isomeride (Rüemann), T., 627; P., 53.

Keto-2-phenylanthrazetrazone (Pier-ron), A., i, 926.

3-Keto-1:2:5:4-tetramethylpyrroliidine, 4-amino-, and its phenylthiocarbonamide (Kohn), A., i, 829.

INDEX OF SUBJECTS. 1353

4-Keto-2-thio-5-methylthiazolidine-3-acetic acid (Körner), A., i, 510.
4-Keto-2-thiothiazolidine-3-acetic acid. See Rhodanine acid.
5-Keto-2:2:4-trimethyltetrahydrofuran, 4-amino-, and its phenylthiocarbamide (Kohn), A., ii, 875.

Kidney, frog's, colloid nature of pigments in relation to their behaviour in the (Höber and Kempner), A., ii, 716; (Höber and Chassin), A., ii, 875.

Kidneys, action of the digitalis group on the (Jonescu and Loewi), A., ii, 720.

perfused, tissue respiration in (Verdon), A., ii, 53.

Kidney secretion of indigo-carmin, methylene-blue, and sodium carminate (Shaper), A., ii, 769.

Kinetic theory, application of, to the metals (Reboul), A., ii, 934.

Kinetics. See under Affinity, chemical.

Kiri-abura. See Wood oil, Japanese.

Kjeldahl's method (Salkowski), A., ii, 1070.

Kröhnikte from Chile (Palache and Warren), A., ii, 1047.

Krypton, xenon, helium, and neon, percentage of, in the atmosphere (Ramsay), A., ii, 688.

density of (Moore), T., 2181; P., 272.

L.

Laccase, oxidations with, in presence of salts (V. Euler and Bolin), A., ii, 1021.

Lacquer, Japanese (Miyama), A., i, 437.

Lactaldehyde, synthesis of, and its derivatives (Wohl and Lange), A., i, 942, 943.

Lactaldehydecetal, preparation and reactions of (Wohl and Lange), A., i, 942, 943.

Lactam, C11H12O2N2 from α-benzylationinoisobutyramide (Mohr and Geis), A., i, 339.

C15H16O2N, from the menthylurethane of ethyl lactate (Vallee), A., i, 976.

Lactic acid (i-ethylidene-lactic acid, α-hydroxypropionic acid), formation and decomposition of, by micro-organisms (Meissner), A., ii, 414.

in eclampsia (ten Doesschate), A., ii, 122; (Donath), A., ii, 213.

formation of, in muscle (Latham), A., ii, 609.

action of, on the isolated and surviving heart of mammals (Backman), A., ii, 612.

in wine (Paris), A., ii, 543.

comparison of methods of estimating (Trummer), A., ii, 905.

estimation of, in animal fluids and organs (Jerusalem), A., ii, 905.

estimation of, in lactates (Paessler), A., ii, 498.

estimation of, in musts and saccharine liquids (Legler), A., ii, 438.

Lactic acid, bismuth salts (Telle), A., i, 851.

glucinum salt (Glasmann and Novicky), A., i, 121; (Tanatar and Kurovski), A., i, 759.

2-Lactic acid (paralactic acid, sarcolactic acid), formation of, in the autolysis of muscle (Inouye and Kondo), A., ii, 209.

Lactic acids, thio-, optically active (Lovén), A., i, 714.

Lactic acid fermentation. See under Fermentation.

Lactone, C6H10O2N, and its acetyl and bromo-derivatives, from 3-methylpyrazolone and ethyl acetocetate (Wolff and Schreiner), A., i, 291; (Bülow and Schaub), A., i, 579.

C9H10O2N2 from 3-methylpyrazolone and ethyl methylacetocetate (Wolff and Schreiner), A., i, 291.

C10H12O2N2 from 1:3-dimethylpyrazolone and ethyl methylacetocetate (Wolff and Schreiner), A., i, 291.

β-Lactone, C29H14O3, from diphenylketen and quinone (Staudinger), A., i, 410.

Lactone dyes (Herzig and Epstein), A., i, 899.

Lactones and the corresponding hydroxyacids, pharmacological action of certain (Marshall), A., ii, 1060.

of the pyrazole series (Wolff and Schreiner), A., i, 291.

β-Lactones, formation of (Staudinger), A., i, 410, 411.

γ-Lactones, formation of (Shuboff and Schestakoff), A., i, 755.

Lactones. See also Iodolactones.
Lactose (milk sugar) and its derivatives, scission of, by diastase (Bierry and Giaja), A., i, 1031.

forms of (Hudson), A., i, 952.

heats of solution of the three forms of (Hudson and Brown), A., ii, 665.

action of calcium hydroxide on (Killian), A., i, 128, 715.

condensation of, with formaldehyde (Rosenberg), A., i, 320.

estimation of (Shimizu), A., ii, 991.

estimation of, in milk (Carrez), A., ii, 236; (Guérin), A., ii, 329.

Lavulose-\(\alpha\)-nitrophenylhydrazone (fructosazine, 2:5-ditetracycloxybutylpyrazine) and its octa-acetyl derivative (Stölte), A., ii, 51.

degradation of, in the animal body (Stölte), A., i, 833.

Lavulose (d-fructose), fermentation of, by yeast juice (Harden and Young), P., 115.

oxidation of (Nef), A., i, 7.

behaviour of, towards dilute sodium hydroxide (Meisenheimer), A., i, 319.

in diabetic urine (Borchardt), A., ii, 518.

tetra- and penta-acetates, crystallised (Brauns), A., i, 320.

precipitation of, by basic lead acetate (Geerligs), A., ii, 991.

detection of, in presence of other natural sugars (Pieraerts), A., ii, 542.

Lavulose-o-nitrophenylhydrazone (Reclaire), A., i, 1014.

Lamp, Hefner. See Hefner lamp.

Langbeinite and vanthoffite (Nacken), A., ii, 692.

Lanthanum ammonium molybdate (Barbier), A., ii, 595.

sulphate, formation of, from lanthanum oxide by sulphuric acid (Wirth), A., ii, 570.

disulphide (Biltz), A., ii, 1038.

Lanthanum, cerium, and didymium, quantitative spectra and separation of (Pollok and Leonard), A., ii, 645.

Lassallite. See Pilolite.

Latent heat of fusion. See under Thermochemistry.

Laterite, origin of (Chautard and Lemoine), A., ii, 203.

Laurane, \(C_{29}H_{52}\) from laurel oil (Matthews and Sandier), A., i, 418.

Laurel-leaf oil (Hänsel), A., i, 665.

Laurel oil, "unsaponifiable matter" of (Matthews and Sandier), A., i, 417.

Lauric acid, \(\alpha\)-hydroxy- (Power and Rogerson), A., ii, 725.

Lavas of the recent eruption of Etna (Lacroix), A., ii, 766.

Lavender oils, observations on the analysis of (Jeanard and Satie), A., ii, 232.

Lead, atomic weight of (Baxter and Wilson), A., ii, 281.

electrochemistry of (Cumming), A., ii, 248.

heating effects produced by Röntgen rays in (Bumstead), A., ii, 342.

and selenium, freezing-point diagram of (Friedrich and Leroux), A., ii, 696.

poisoning. See under Poisoning.

Lead alloys with aluminium (Gwyer), A., ii, 286.

with antimony, estimation of arsenic in (Howard), A., ii, 428.

with calcium (Doński), A., ii, 279.

with cobalt (Ducelliez), A., ii, 594; (Lewkonja), A., ii, 553.

with nickel (Voss), A., ii, 195.

with palladium, nature of (Pushin and Pashsky), A., ii, 860.

with tin (Rosenhain and Tucker), A., ii, 1038.

hardness of (Saposhnikoff), A., ii, 294.

estimation of lead in (Holzmann), A., ii, 633.

Lead compounds, solubility of, in water (Pleissner), A., ii, 40.

Lead chloride, analysis of (Baxter and Wilson), A., ii, 281.

ammonium chromate (Gröger), A., ii, 691.

hydroxide, heterogeneous colloidal (Szilárd), A., ii, 197.

potassium periodide, Wells’, composition and formula of (Meldrum), P., 97.

nitrate and sodium nitrate, temperatures of spontaneous crystallisation of mixtures of (Isaac), T., 384; P., 30.

nitrites (Chilesotti), A., ii, 845, 948.

potassium nitrites, complex (Meldrum), P., 97.

oxides, velocity of reduction of, by carbon monoxide and the existence of a suboxide (Brislee), T., 154.

peroxide, formula of, and the action of selenious acid on (Mainino), A., ii, 106, 833.

Triplumbic tetroxide (red lead), examination of (Partheil), A., ii, 69, 227.

assay of (Sacher; Piesczek), A., ii, 228; (Beck), A., ii, 777.

comparison of two tests for (Dunlap), A., ii, 537.
Lead sulphate, compound of, with arsenic sulphate (Kühl), A., ii, 36.
sulphide and its oxidation products, equilibrium in the reaction between (Schenck and Rassbach), A., ii, 947.
analysis of (Jacobsen), A., ii, 989.
Lea/s and silver assays in ores, dry (Loevy), A., ii, 328.
estimation of, volumetrically (Bollenbach), A., ii, 68; (Roch), A., ii, 227.
estimation of, in alloys (Elborne and Warren), A., ii, 735.
estimation of, in lead-tin alloys (Holzmann), A., ii, 633.
estimation of, in ores (Low), A., ii, 536.
copper, and silver, estimation of, in complicated organic salts (Rindl and Simonis), A., ii, 432.
See also Radio-lead.
Lead ions, univalent, existence of, in aqueous solutions (Denham and Allmand), T., 424; P., 14.
Leaf, causes of the displacement of absorption bands in the (Iwanowski), A., ii, 57.
Leaves, yellow autumn, pigment of (Tsvett), A., i, 279.
Lechithid formation (Kyes), A., ii, 215.
Lecithin, chemistry of (Mayer), A., i, 243.
methods for the preparation of, from plant seeds (Schulze), A., i, 385.
physico-chemical researches on (Porges and Neubauer), A., ii, 90.
stability of (Long), A., i, 385.
behaviour of, with bile salts, and its occurrence in bile (Long and Gephardt), A., ii, 872.
behaviour of emulsions of, with metallic salts and certain non-electrolytes (Long and Gephardt), A., i, 385.
preparation of choline from (Riedel), A., i, 395.
quantitative recovery of choline from (Moruzzi), A., i, 395; (Maclean), A., i, 396.
the biological importance of (Glikin), A., ii, 120.
of the heart muscle, amount of choline in (Maclean), A., ii, 967.
partition of, in the organism (Nerkeing), A., ii, 608.
phosphorus compounds of (Ehrenfeld), A., i, 598.
estimation of, in milk (Nerking and Haensel), A., ii, 999.

Leesbergite, the so-called (Bruhns), A., ii, 703.
Legumelin from the pea, hydrolysis of (Osborne and Heyl), A., i, 928.
Legumin from the vetch, hydrolysis of (Osborne and Heyl), A., i, 843.
Lemon, estimation of citral in essence of (Bruylants), A., ii, 390.
Lemon grass oil, estimation of citral in (Bloch), A., ii, 782.
Lemon oil, detection of small quantities of turpentine in (Chace), A., ii, 908.
Lens, crystalline, chemico-physical investigation of the (Bottazzi and Scalinci), A., ii, 966, 1054.
Lepidolite, manufacture of lithia from (Schieffelin and Cappon), A., ii, 690.
Leucine (a-aminoo-hexoic acid) and its salts and methyl derivative and its aurichloride (Kudielka), A., i, 511.
from casein (Heckel), A., i, 231.
from the ligamentum nuchae of oxen (Samec), A., i, 231.
fraction from protein hydrolysis (Ehrlich and Wendel), A., i, 302.
resolution of, into its optical components, and its formyl derivatives (Marko), A., i, 772.
oxidation of, with hydrogen peroxide (Dakin), A., i, 80.
L-Leucine derivatives, synthesis of (Abderhalden and Hirszowski), A., i, 887.
L-Leucine (a-aminoo-β-methylvaleric acid), preparation of, from the hydrolytic products of proteins (Leuvene andJacobs), A., i, 375.
synthesis of (Ehrlich), A., i, 396; (Briaschi and Friedmann), A., i, 607.
Leucines, isomeric, behaviour of, in the liver (Emiden), A., ii, 515.
Leucite, utilisation of (Manuelli), A., ii, 386.
influence of micro-organisms on the utilisation of the potassium in, by plants (De Grazia and Camiola), A., ii, 415.
as manure (Alvisi and Venditori), A., ii, 61; (Monaco), A., ii, 424.
Leucoaliizarin (1:2-dihydroxyanthranol) (Grandmougin), A., i, 786.
Leuco-base, C15H9N3, from naphtho-blue (Noelting and Phillips), A., i, 296.
Leucocytes, the death of (Ross), A., ii, 868.
the vacuolation of (Ross), A., ii, 868.
INDEX OF SUBJECTS.

Leucamines of cod liver oil (Hawk), A., ii, 308.
Leuco-2-methylisorosindone diacetate (Keirrmann and Stern), A., i, 221.
Leucoprotease and anti-leucoprotease of mammals and birds (Opie and Barker), A., ii, 117.
Leucoquinizarin (Grandmougin), A., i, 808.
Lecorosindone diacetate (Keirrmann and Stern), A., i, 221.
Leuco-4-methylisorosindone diacetate (Keirrmann and Stern), A., i, 221.
Leucotannin and its acetyl derivatives (Nierrenstein), A., i, 91.
Leucothioindigotin and its diacetyl derivative (Friedlander), A., ii, 59.
Leucyl-$\beta$-aminobutyric acid and its copper salt and anhydride (Kay), A., i, 773.
Leucyl-$l$-histidine and its copper salt (Fischer and Cone), A., i, 1005.
Leucyl-$d$-methyisoserines, $A$- and $B$, and their phenylearbinides (Kay), A., i, 774.
L-Leucyl-$l$-tyrosine (Arberdhalen and Hirszowsky), A., i, 888.
L-Leucyl-$d$-valine and its methyl ester and anhydride (Fischer and Scheiber), A., i, 958.
Light. See under Photochemistry.
Lignin, composition and reactions of (Klason; Klason and Fagerling), A., i, 717.
Cellulose, and cutin, separation of (Köng; Matthes), A., ii, 286.
Lignosulphonic acid, barium salt (Klason), A., i, 717.
Lime. See Calcium oxide.
Limulus heart, muscle and nerve of, relative resistance of, to drugs (Meek), A., ii, 308.
Linaloe seeds, oil from (Roure-Bert and Fils), A., i, 558.
Linalool, hydrogenation of, by means of nickel and hydrogen (Enklaar), A., i, 934.
Dithizonide (Erdmann), A., ii, 831.
Linalyl acetate, thiozonic acid of (Erdmann), A., ii, 831.
Methyl ether (Bacon), A., i, 815.
Linaria, glucosides of (Klobb), A., i, 903.
Linarine phenol and its acetate (Klobb), A., i, 904.
Linking, carbon-nitrogen, which substances contain a readily resolvable single (Emde), A., i, 83.
Linkings, conjugated, addition of the higher oxides to (Wieland and Stenzl), A., i, 517.
Linkings, double and treble, action of ozone on (Harrises), A., i, 75, 387; (Molinari), A., i, 244, 349.
Resolution of, by addition of water to terpene compounds (Wallach), A., ii, 429.
Linseed oil, alcoholysis of (Haller), A., i, 123.
Lipase in embryonic tissues (Mendel and Leavenworth), A., ii, 207.
inhibiting action of fluorides on (Amberg and Loewenhart), A., i, 235.
Lipoids (Fränkel; Bolaffio), A., i, 377.
Percentage of iron in (Glikin), A., ii, 407.
Lipolysis, agglutination, and hemolysis (Neuerg), A., ii, 708.
Lippianol from Lippia scaberrima (Power and Tunin), A., ii, 59.
Lippia scaberrima (Levkooss Boss), constituents of (Power and Tunin), A., ii, 59.
Liqueurs, identification of thujone in (Duparc and Monnier), A., ii, 996.
Liquid, polarimetric measurements with small quantities of (Donau), A., ii, 647.
Liquid mixtures, electro-optical properties of (Chaudier), A., ii, 788.
Liquids, new method for determining the specific heats of (Richards and Rowe), A., ii, 806.
torsional elasticity of (Lauer and Tammann), A., ii, 667.
surface tension of, investigated by the method of jet vibration (Pedersen), A., ii, 158.
relation between compressibility, surface tension, and other properties of (Richards and Matthes), A., ii, 158.
which boil above 100°, apparatus for estimating the expansion of (Thörner), A., ii, 907.
time-law of the capillary rise of, and the relationship of velocity to the chemical constitution (Ostwald and Goppelbroeder), A., ii, 263.
density of, below zero (Timmermans), A., ii, 85.
determination of the molecular weights and critical temperatures of, by the aid of drop weights (Morgan and Stevenson), A., ii, 356; (Morgan and Higgin), A., ii, 668.
polymorphism of (Vorländer), A., ii, 22.
INDEX OF SUBJECTS. 1357

Liquids, fermented, detection of methyl alcohol in (Wolfe), A., ii, 72.
fermenting, simple form of apparatus for observing the rate of absorption of oxygen by (Adeney), A., ii, 781.
Lithia. See Lithium oxide.
Lithium, in radioactive minerals (Gleditsch), A., ii, 9, 246; (Ramsay and Cameron), A., ii, 247.
thermo-electric organic, inflammable, of low boiling point, relation between the ignition temperature and the vapour pressure of (Charitschkoff), A., ii, 255.
organic, detection of free acids in (Repton), A., ii, 781.
Liquorice, sweet substance from (Rase-Nack), A., i, 818.
Lithium chloride, conductivity and viscosity of solutions of (Green), T., 2023; P., 187.
and sucrose, conductivity and viscosity of mixtures of solutions of (Green), T., 2049; P., 187.
effect of water on the decomposition curves of, in acetone and in pyridine (Patten and Mott), A., ii, 253.
solutions of, in liquid ammonia (Ruff and Zedner), A., ii, 585.
Lithium, molecular volume of (Rau), T., 998; P., 75.
oxide (lithia), manufacture of, from lepidolite (Schieffelin and Cappion), A., ii, 690.
thioantimonates (Donk), A., ii, 763, 839.
Liver, capacity of, the to reverse the optical action of sugars (Pflüger), A., ii, 307.
can the, form glycogen from optically active amino-acids? (Grube), A., ii, 516.
the smallest molecule from which the, can make glycogen (Grube), A., ii, 307.
changes in the nitrogenous constituents of the, when the kidneys are placed out of action (Olivi), A., ii, 407.
Liver, higher fatty acids in the, after removal (Leathes), A., ii, 1054.
behaviour of isomeric leucines in the (Emden), A., ii, 515.
formation of acetoacetic acid in the (Emden and Engel), A., ii, 515.
formation of acetone in the (Emden and Marx), A., ii, 515.
the iron of the (Scaffidi), A., ii, 210.
the nucleo-protein of the (Levene and Mandel), A., i, 587.
in chloroform necrosis (Wells), A., ii, 974.
of birds, formation of uric acid in the (Friedmann and Mandel), A., ii, 1054.
of diabetic dogs, formation of acetoacetic acid in the (Emden and Lattes), A., ii, 515.
of the horse, jeconin and other lecithin-like substances from the (Baskoff), A., i, 1029.
of reptiles. See Reptiles.
Liver autolysis. See under Autolysis.
Liver disease, excretion of creatine and creatinine in (Mellanby), A., ii, 54.
Livetin from egg-yolk (Plimmer), T., 1501; P., 190.
Lolium temulentum, fixation of free atmospheric nitrogen by, infested with a fungus (Hannig), A., ii, 523.
Long leaf pine oil (Teeple), A., i, 355.
Lonicera Xylotoma, pectins from the fruit of (Bridel), A., ii, 125.
Lubricating oils. See under Oils.
Luminescence, fluorescence, and chemical constitution (Hantzsch), A., ii, 446.
Lung-tissue, decomposition of fat by (Sieber), A., ii, 406.
Lupeol (van Romburgh), A., i, 39; (Cohen), A., i, 882.
and its butyrate (Cohen), A., i, 884.
Luteolium (Urbain), A., ii, 283, 849.
Lutidinamide (v. Meyer and Henning), A., i, 911.
Lutidines. See Dimethylpyridines.
Lycopersicum esculentum. See Tomatoes.
Lymph, lymphagogue action of (Carlson, Green, and Beck), A., ii, 611.
excess of chlorides in (Carlson, Green, and Luckhardt), A., ii, 610.
Lymph formation, relative hemolytic power of lymph and serum under various conditions of (Hughes and Carlson), A., ii, 304.
Lymph glands. See Glands.
Lysine, arginine, and histidine, amount of, in the hydrolytic products of various animal tissues (Wakeman), A., ii, 209.

additive salts of (Ackermann), A., ii, 774.

Lysinogen of the blood-disks (Takaki), A., ii, 512.

Magnesium. See Magnesium oxide.

Magnesio-acetylene bromide and its reactions (Oddo), A., i, 748.

Magnesite stone, artificial, composition of (Cornu), A., ii, 590.

Magnesites, estimation of magnesium oxide in (Mayrhofer), A., ii, 431.

Magnesium and its hydride, spectrum of, as obtained by spark discharges under reduced pressure (Brooks), A., ii, 242.

action of metallic, on certain fatty acids (Fenton and Sisson), A., i, 243.

action of, on esters of brominated fatty acids (Zeltnier), A., i, 243; (Stolle), A., ii, 510.

direct interaction of, with alkyl haloids (Spencer and Crewdson), T., 1821; P., 194.

interaction of, with aryl haloids (Spencer and Stokes), T., 68.

and calcium, antagonistic action of (Melzer and Auer), A., ii, 312, 519.

Magnesium alloys with copper (Urazoff) A., ii, 186; (Sahmen), A., ii, 187.

with nickel (Voss), A., ii, 195.

Magnesium compounds, colloidal and gelatinous (Neuberg and Rewald), A., ii, 39.

Magnesium salts, abnormal behaviour of, on hydrolysis (Denham), A., ii, 380.

Magnesium bromide and iodide, molecular compounds of, with organic substances, reciprocal displacement of the constituents of, and their relative stability (Menschutkin), A., ii, 170.

carbide, formation of (Piring), T., 2106; P., 241.

carbonate, reaction of, with potassium hydrogen carbonate and water (Büchner), A., ii, 184.

artificial, agronomical equivalent of (Kanamori), A., ii, 625.

ammonium chromate (Gröger), A., ii, 690.

oxide (magnesia), reducibility of, by carbon (Slade), T., 327; P., 29.

Magnesium oxide and lime, ratio of, for the mulberry tree (Nakamura), A., ii, 126.

estimation of, in magnesites (Mayrhofer), A., ii, 431.

oxychloride formed by electrolysis of the residual solutions from the manufacture of potassium chloride, and its importance for the preparation of bromine (Hof), A., ii, 946.

phosphate, compound of, with methylamine (Francois), A., i, 505.

silicido (Lebeau and Bossuet), A., ii, 184.

sulphate and potassium sulphate system and magnesium sulphate and sodium sulphate system (Nacken), A., ii, 69.

influence of, on metabolism (Steel), A., ii, 767.

manuring with (Daikuhara), A., ii, 139.

top-dressing with (Zirker), A., ii, 625.

Magnesium organic compounds, isomeric (Schmidlin and Hodgson), A., i, 239.

action of, on arsenious oxide (Sachs and Kantorowicz), A., i, 1031.

action of, on ethyl orthosilicate (Khotinsky and Seregenkoff), A., i, 1032.

reducing properties of (Letellier), A., i, 242.

Magnesium ammonium and magnesium oxonium compounds, reciprocal transformations of (Tschelinzeff), A., i, 254.

benzyl, cymyl, and tolyl chlorides (Hesse), A., i, 592.

methiodide, compound of, with amyl ether (Zerrwittinoff), A., i, 616.

phenyl bromide, action of chloromethyl ether on (Reychler), A., i, 159.

See also Grignard's reaction.

Magnesium, estimation of, volumetrically (Rosenthaler), A., ii, 67; (Reifton), A., ii, 632.

separation of, from the alkalis by alcoholic ammonium carbonate (Gooch and Eddy), A., ii, 632.

Magnesium-pectolite from the diabase of Burg, Hesse-Nassau (Reuning), A., ii, 201.

Magnetic behaviour of air, argon, and helium in relation to oxygen (Tännler), A., ii, 152.

double refraction. See under Photochemistry.

field, chemical reactions in a (Berndt), A., ii, 756.
INDEX OF SUBJECTS.

Magnetic field, decomposition of complex chemical compounds in a variable (ROSENTHAL), A., ii, 152.

See also Molecular magnetic field. rotation. See under Photochemistry. susceptibilities of complex ferric salts (PASCAL), A., ii, 756.
of certain iron compounds (BERNDT), A., ii, 1013.
of the oxygenated metallic radicals (PASCAL), A., ii, 756, 927.

Magneto-optical phenomena, use of very low temperatures for the study of (BECQUEREL), A., ii, 3.

Magnolia kobus, essential oil of (CHARABOT and LALOUE), A., i, 196; (ROURE-BERTRAND FILS), A., i, 558; (SCHIMMEL & CO.), A., i, 666.

Maize, effects of feeding with (BAGLIONI), A., ii, 619.

manganese compounds as fertilisers for (SUTHERST), A., ii, 528.

proteins of. See under Proteins.

Malachite-green, leuco-base of, reaction of, with hemoglobin (BUCKMASTER), A., ii, 643.

Malacone, a silicate of zirconium (CUMMING), T., 350; P., 28.

composition of (TSCHERNIK), A., ii, 862.

Maleic acid, alkaldioal salts, and their optical activity (HILDITCH), T., 704; P., 61.

Maleic acid, basic ferric salt (SCHOLZ), A., i, 604.

Maleic acid: dihydroxy-, titanium derivative. See Titan-di-dihydroxymaleic acid under Titanium.

Malic acid in the production of wine (MESTREZAT), A., ii, 723.

fermentation of, in the production of wine (ROSENSTIEHL), A., ii, 772.
estimation of (POZZI-ESCOT), A., ii, 1078.
estimation of, in food products (COWLES), A., ii, 904.

Maleic acid. bismuth salt (TELLE), A., i, 851.

ferric, ferrous, and basic ferric salts (ROSENTHALER and ZIEBECK), A., i, 246.

Malonaldehyde, nitro-, condensation of, with acetylacetone (HALE and ROBERTSON), A., i, 634.

Malonic acid and its ester, preparation of, from chloroacetic acid (PHELPS and TILLOTSON), A., i, 757.
esterification of (PHELPS and TILLOTSON), A., i, 756.

Malonic acid, condensation of, with aldom and crotonaldehyde (RIEDEL), A., i, 501.

influence of substituting groups on the reactions of derivatives of (EINHORN, v. DIESBACH, FEIBELMANN, and LADISCH), A., i, 312.

complex iron compounds of (MATSUI), A., ii, 853.
thioanilide of (RHUMANN), T., 624.

Malonic acid, ferrons and ferric alkali salts (SCHOLZ), A., i, 603.
rare earth salts (ERDMANN and WIRTH), A., ii, 694.

Malonic acid, ethyl ester, action of phenylthiocarbamide on (RHUMANN), T., 621; P., 53.
sodium derivative, action of allylthiocarbamide on (RHUMANN), T., 625.

action of monochloromethyl ether on (SIMONSEN), T., 1777; P., 212.
methyl ester, condensation of, with αβ-unsaturated aldehydes (MEERWEN), A., i, 90.

Malonic acid, cyan-, ethyl ester, thioanilide of, and its salts (RHUMANN), T., 626.

action of ethyl chloroacetate on (RHUMANN), T., 627; P., 53.
nitro-, ethyl ester, ammonium derivative, action of formaldehyde on, diethylamine salt, and nitrosoamine (BATTAGLIA), A., i, 396.

Malonic semichloride (STAUDINGER and OTT), A., i, 602.

Malonyl bromide, dibromo- (STAUDINGER and KLEVER), A., i, 318.
derivatives, halogenated, liberation of iodine from hydrorobic acid by certain (WHITELEY), P., 283.

Malonylanilideoxime, 3-mitroso-, and its anilide salt (WIELAND and GEMELIN), A., i, 1013.

Malonylisobutyrazoneaconoacetic acid, ethyl ester, a substance with three reactive methylene groups (BULOW), A., i, 253.

Malonylureide, ethyl ester (BOHRINGER & SÖHNE), A., i, 464.

Malt, the soluble and non-coagulable nitrogen compounds in (BROWN), A., ii, 883.

water-soluble polysaccharides of (BROWN), A., ii, 973.

Maltase, physico-chemical investigation of (PHILOCHE), A., i, 712; ii, 470.
Maltose and its derivatives, scission of, by diastase (Briery and Giaja), A., i, 1031.

Mammalian uterus. See Uterus.

Mammals, heart of. See Heart.

leucoprotease and anti-leucoprotease of (Opie and Barker), A., ii, 117.

p-Mandelic acid, velocity of esterification of, by means of alcoholic hydrogen chloride (Kailan), A., ii, 28.

Mandelonitrile glucoside, Fischer’s, formation of (Auld), T., 1281; P., 182.

Manganese and the periodic law (Reynolds), A., ii, 41.

Manganese alloys, preparation of (Dieffenbach), A., ii, 697.

action of, on potatoes and sugar beet (Gregoire, Hendrick, and Carpain), A., ii, 529.

as fertilisers for maize (Sutherst), A., ii, 528.

with aluminium (Hindrichs), A., ii, 857.

Manganese salts, is the manurial action of, observable in the field? (V. Feilitzen), A., ii, 61.

influence of, on vegetation (Rhodin), A., ii, 980.

Manganese carbide (Stadeler), A., ii, 592.

nitride, Mn₃N₄ (Henderson and Galley), A., ii, 485.

Manganese compounds, preparation of (Dieffenbach), A., ii, 697.

action of, on potatoes and sugar beet (Gregoire, Hendrick, and Carpiaux), A., ii, 529.

as fertilisers for maize (Sutherst), A., ii, 528.

with aluminium (Hindrichs), A., ii, 857.

Manganese compounds, preparation of (Hindrichs), A., ii, 856.

with copper (Sahmen), A., ii, 187.

Manganese compounds, preparation of (Dieffenbach), A., ii, 697.

action of, on potatoes and sugar beet (Gregoire, Hendrick, and Carpiaux), A., ii, 529.

as fertilisers for maize (Sutherst), A., ii, 528.

with aluminium (Hindrichs), A., ii, 857.

Manganese salts, is the manurial action of, observable in the field? (V. Feilitzen), A., ii, 61.

influence of, on vegetation (Rhodin), A., ii, 980.

Manganese carbide (Stadeler), A., ii, 592.

nitride, Mn₃N₄ (Henderson and Galley), A., ii, 485.

Manganese compounds, preparation of (Dieffenbach), A., ii, 697.

action of, on potatoes and sugar beet (Gregoire, Hendrick, and Carpiaux), A., ii, 529.

dioxide and dimanganese trioxide, dissociation temperatures of, in air and oxygen (Meyer and Rögers), A., ii, 191.

action of hydrochloric acid on (Holmes and Manuel), A., ii, 765.

Permanganate solutions, optical investigation of the condition of (Hantzsch and Clarke), A., ii, 646.

Manganese silicate and calcium silicate, isomorphism of (Ginsberg), A., ii, 842.

sulphate and sodium fluoride, action of, on onions (Namba), A., ii, 618.

sulphide, spontaneous combustion of (Binder), A., ii, 192.

Manganous chloride, transition temperature of (Richards and Wrede), A., ii, 16.

Manganese:

Manganous oxide, reduction of, by carbon (Greenwood), T., 1491; P., 188.

ammonium sulphates (Lang), A., i, 350.

Manganese, detection and estimation of small quantities of (Duyk), A., i, 70.

and chromium, detection of, in presence of each other (Karslake), A., ii, 635.

modification of Volhard’s method of estimating (Mayer), A., ii, 71.

estimation of, by means of potassium ferricyanide (Bollenbach and Luchmann), A., ii, 1074.

estimation of, volumetrically, in iron and steel (Raymond), A., ii, 323.

estimation of, in iron and manganese ores (Onthry), A., ii, 598.

estimation of, volumetrically, in steel (Sacerdotti), A., ii, 228.

estimation of, in potable water (Eryn耶), A., ii, 135.

use of ammonium persulphate in the separation of, from copper in acid solutions (Gottschalk), A., ii, 433.

separation of, from iron (Moore and Miller), A., ii, 434.

Manganese and iron minerals from the crystalline schists of Brosteni, Roumania (Butureanu), A., ii, 955.

Manganese ore deposits of the Queluz District, Brazil (Derby), A., ii, 506.

Manganese compounds. See under Manganese.

Mangolds, experiments with different varieties and on the storage of (Sjollema and van Daalen), A., ii, 618.

manurial experiments on, with calcium cyanamide and sodium nitrate (Klapper), A., ii, 619.

Mannitol hydrogen peroxide (Tanatar), A., i, 400.

Mannose, fermentation of, by yeast juice (Harden and Young), P., 115.

\(\alpha\)-Mannose, oxidation of (Nef), A., i, 7.

Mannose-\(\alpha\)- and -\(\beta\)-nitrophenyl-hydrzones and \(\alpha\)-nitrophenyloseazone (Reclaire), A., i, 1014.

Manometer, simple, for vacuum distillation (Gebhard), P., 51.

Mantles, incandescent, application of combustion without flame to lighting with (Meunier), A., ii, 463.

Manures, influence of, on the composition of wheat (Snyder), A., ii, 528.

green, persistence of the nitrogen of, in a light sandy soil (V. Seelhorst), A., ii, 727.
Manures, phosphatic, relation between the increased yield due to, and the amount of phosphoric acid in the soil (PILZ), A., ii, 423.

estimation of alkaline earths in (FOERSTER), A., ii, 1072.

estimation of potassium in (SCHENKE), A., ii, 321.

Manurial experiments, pot culture experiments in 1906-7 (VOELCKER), A., ii, 622.
on barley (DAIKUHARA), A., ii, 128.
on crops (WAGNER), A., ii, 1066.
on oats (SEIDLER and STUTZER), A., ii, 1065.
on pasture land (SOLBERG), A., ii, 422.
on sugar beet (ANDERLIK and URBAN), A., ii, 219, 1066; (GREGOIRE, HENDRICK, and CARPIAUX), A., ii, 529.

with ammonium salts, calcium cyanamide, and sodium nitrate (WAGNER, HAMANN, and MÜNZINGER), A., ii, 622.

with ammonium nitrate (PFRIFFER, HEFFNER, and FRANK), A., ii, 980.

with ammonium sulphate (BACHMANN), A., ii, 980; (NAZARI), A., ii, 1068.

with ammonium sulphate, calcium cyanamide, calcium nitrate, and sodium nitrate (NAZARI), A., ii, 1068.

with ammonium sulphate and sodium nitrate (BAESSLER), A., ii, 127; (CLAUSEN), A., ii, 981.

with basic slag-ammonia (BACHMANN), A., ii, 624.

with calcium cyanamide (REMY; ASCHMAN and AREND; LÖHNIS and SABASCHNIKOFF), A., ii, 220; (STUTZER; NAMBA and KANOMATA; SJOLLEMA and DE WILDT), A., ii, 623; (HASELHOFF; KAPPEN), A., ii, 728.

under different conditions (UCHIYAMA), A., ii, 128.

with calcium cyanamide and Swedish calcium nitrate (v. FEILITZEN), A., ii, 590.

with calcium cyanamide and sodium nitrate for mangolds (KLÖPFEL), A., ii, 619.

with calcium cyanamide for potatoes (STUTZER), A., ii, 726.

with calcium nitrate and calcium cyanamide (v. FEILITZEN), A., ii, 890.

with lime (KANOMATA), A., ii, 624; (GUTHRIE and COHEN), A., ii, 889.

Manurial experiments, with lime and magnesia for the mulberry tree (NĀKAMURA), A., ii, 126.

with precipitated calcium phosphate (SÖDERBAUM), A., ii, 423.

with dicyanodiamide (LOEW), A., ii, 775.

with gypsum (TAKEUCHI), A., ii, 624.

with leucite (ALVISI and VENDITTO), A., ii, 61; (MONACO), A., ii, 424.

with artificial magnesium carbonate (KANAMORI), A., ii, 625.

with magnesium sulphate (DAIKUHARA), A., ii, 129; (ZIKKER), A., ii, 625.

with manganese compounds (SÜTHERT), A., ii, 528; (GRÉGOIRE, HENDRICK, and CARPIAUX), A., ii, 529.

with magnesium salts (v. FEILITZEN), A., ii, 61; (RHODIN), A., ii, 981.

with different kinds of nitrates (SREBLIEN), A., ii, 61.

with nitrogen in 1907 (SÖDERBAUM), A., ii, 980.

with organic nitrogen, as compared with sodium nitrate (POPP), A., ii, 727.

with old and new nitrogenous manures (NAZARI), A., ii, 1068.

with new nitrogenous manures (v. FEILITZEN), A., ii, 981.

for hemp (STÖHR), A., ii, 421.

with sodium nitrate and ammonium sulphate (BAESSLER), A., ii, 127; (CLAUSEN), A., ii, 981.

See also Plants and Soils.

Manurial trials, Swedish (BOLIN), A., ii, 422.

Manurial value of bone dust (UCHIYAMA), A., ii, 128.
of bone and mineral phosphates (MONTANARI), A., ii, 128.

Marcitine and its anirichloride (ACKERMANN), A., i, 10.

Mariotte-Boyle law, application of a deduction from the (REBENSTORFF), A., ii, 565.

Mariotte's law, apparent deviations from, and their influence on the measurement of small pressures (SCHERL and HEUSE), A., ii, 1016.

Marmot, comparison of the hemolytic and toxic action of eel's serum on the (CAMS and GLEY), A., ii, 215.

Marrubic acid and its salts and ethyl ester, and Marrubin (GORDIN), A., i, 344.

Marsh gas, exact analysis of (GRÉHANT), A., i, 493.
Mass of suitable precipitates, possibility of determining the, by observation of their rates of settling (Kohn), A., ii, 92.

Mass action and Mass law. See under Affinity, chemical.

Matter, constitution of (Pissaljemsky), A., ii, 478.

indestructibility of, and the absence of exact relations among the atomic weights (Comstock), A., ii, 477.

liquid-crystalline state as a general property of (v. Weimarn), A., ii, 1023.

Measuring vessel and pipette, rapid (Schubert), A., ii, 424.

Meat, creatine and creatinine in (Emmett and Grindley), A., ii, 53.

digestion and absorption of, in the intestine (London and Sulima), A., ii, 870.

cured, nitrates in (Richardson), A., ii, 208.

Meat extracts, composition of (Micko), A., ii, 644.

monoamino-acids in (Micko), A., ii, 713.

creatinine and creatinine in (Emmett and Grindley), A., ii, 53.

Meconines (Mermod and Simonis), A., i, 342.

2-m-Meconyl-5-methoxyphenol (Perkin and Robinson), T., 513.

Medical chemistry. See under Chemistry.

Meduse, action of the salts of sea-water on the rhythmic movements of (Bethe), A., ii, 969.

Melabocaal from Sumatra, presence of t-dimethylisoamyl from the latex of (de Jong), A., i, 952.

Molamine, salts of, with acid dyes (Radlberger), A., i, 1001.

Molamins, artificial, and the melanin of the cockchafer (Ishizaka), A., i, 280.

Mollitic acid (benzenehexacarboxylic acid), constitution of the phthaleins of (Silberrad), P., 209.

rhodamines of (Silberrad and Roy), P., 204.

Melting point, relation of, to the surface of the granules of a solid substance (Pawloff), A., ii, 927.

of the anilides, p-toluidides, and a-naphthalides of the normal fatty acids (Robertson), T., 1033; P., 120.

of the elements of the iron group, determination of, by a new radiation method (Burgess), A., ii, 41.

of metals, new method of determining the (Shukoff and Kurbatoff), A., ii, 153.

Melting point of certain osazones (Fischer), A., i, 105.

and boiling points of aromatic sulphides, selenides, and tellurides, and their halogen additive compounds (Lyons and Bush), A., i, 417.

Melting point curves of binary mixtures of o-, m-, and p-nitroanilines (Tingle and Rolker), A., i, 408.

of mixtures of o- and p-nitroanilines (Tingle and Rolker), A., i, 974.

and freezing point curves of binary systems when the solid phase is a mixture (amorphous solid solution or mixed crystals) of the two components (Van Laar), A., ii, 808.

ideal, of binary alloys, correction of the (Mazzotto), A., ii, 660.

Melting points, inverse (Brönsted), A., ii, 509.

Membranes, permeabilities of collodion, gold-beaters’ skin, parchment paper, and porcelain (BigeLOW), A., ii, 88.

Men, healthy, excretion of sugar in (SchenDORff), A., ii, 311.

\( \Delta_{13} \)-Menthadiene. See Carnvene.

\( \Delta_{13} \)-p-Menthadiene. See Origanene.

\( \Delta_{63} \)-m-Menthadiene. See iso-Carvene.

Menthane, 2,4-diamino-, and its derivatives (Harries and Majima), A., i, 734.

Menthazine (Kijner), A., i, 91.

Menthene, thio- (Fromm and McKee), A., i, 991.

\( \Delta^3 \)-Menthene, 2-amino-. See Carvenylamine.

Menthones, o-, m-, \( \Delta^2 \)-, and \( \Delta^4 \)-, and their derivatives (Wallach and Churchill), A., i, 407.

\( \Delta^1 \)-Menthene-4-ol. See Terpinen-4-ol.

\( \Delta^p \)-Menthen-1-ol. See Terpinen-1-ol.

\( \Delta^m \)-Menthene-8-ol. See Dihydroarvestrenol.

Menthone (Wallach and Churchill), A., i, 407.

\( \Delta^1 \)-Menthone and its semicarbazone (Wallach and Meister), A., i, 812.

\( \Delta^1 \)-Menthone and its semicarbazone and dibromide (Wallach and Meister), A., i, 813.

\( l \)-Menthothelyheptanolide (Schimmel & Co.), A., i, 667.

Menthols, m- and \( \delta \) - (Wallach and Churchill), A., i, 407.

Menthols, isomeric, and their acid esters (Pickard and Littlebury), P., 217.

Menthone, action of amyl nitrite on, in presence of sodium ethoxide (Clarke, Lapworth, and Wechsler), T., 36.

p-Menthone, syntheses of optically active (Kötz and Schwarz), A., i, 37.
INDEX OF SUBJECTS.

Menthoneacetal (Arbusoff), A., i, 555.
Menthonephenylhydrzone (Borsche, Witte, and Bothe), A., i, 366.
Menthyl methoxyacetate (Farbenfabriken vorm. F. Bayer & Co.), A., i, 429.
Menthylcarbimide, reactions of (Vallee), A., i, 976.
Mercaptans, addition of, to unsaturated acids (Posner and Baumgarth), A., i, 21.
Mercuriammonium chlorides. See under Mercury.
Mercurous and Mercuric salts. See under Mercury.
Mercury, purification of (Bettel), A., ii, 382.
gradual modification of the first linear spectrum of emission of (Castelli), A., ii, 3.
gaseous, dispersion of (Cuthbertson and Metcalfe), A., ii, 545.
specific heat of (Kurbatoff), A., ii, 807.
recalculation of the vapour pressure of (Laby), A., ii, 1039.
apparatus for the rapid distillation of (Florio), A., ii, 829.
diffusion of metals in (Smith), A., ii, 159.
on-electrolytic solution of, in water and other liquids (Christoff), A., ii, 696.
interaction of, with alloys of other metals (Mallet), A., ii, 187.
physico-chemical considerations as to pharmacological and toxicological actions of (Sabbatini), A., ii, 718.
Mercuriumammonium chloride, ammoniacal (Gaudechon), A., ii, 383.
Dimercuriumammonium chloride and ammonium chloride, double, dissociation of, by water (Gaudechon), A., ii, 188.
Mercury alloys (amalgams) (Smith), A., ii, 38.
conduction of electricity by (Kinsky), A., ii, 754.
with ammonium (Smith), A., ii, 38.
demonstration of the formation of, by electrolysis of ammonium chloride (Schoeder), A., ii, 270.
with calcium and sodium, behaviour of, as electrodes in solutions of neutral salts (Byers), A., ii, 926.
with zinc (Van Deventer), A., ii, 591.
Mercury salts, haemolytic action of (Dunin-Borkowski), A., ii, 1040.
Mercury perchlorate, bromo- and iodo- (Borelli), A., ii, 1039.
thiocyanate- (Borelli), A., ii, 1040.
Mercury ammonium chlorates (Groger), A., ii, 691.
iodide, condensation of, with camphor (Marsh and Struthers), P., 267.
peroxide dyes (v. Antropoff), A., ii, 333.
Mercurous nitrite, molecular volume of (Ray), T., 999; P., 75.
Mercuric salts with complex cations, constitution of (Borelli), A., i, 515; ii, 1039.
rapid estimation of, in aqueous solution (Liversedge), A., ii, 634.
Mercuric bromide or chloride, action of hydrogen phosphide on (Le- moult), A., ii, 35.
bromide and chloride, estimation of the halogen in (Kohn), A., ii, 892.
chloride, ammonium chloride, and water at 30°, in equilibrium (Meerbürg), A., ii, 676.
solutions, effect of glass and traces of organic substances on (Van Ryn), A., ii, 591.
reactions of, with organic acids (Oechsner de Coninck and Daury), A., ii, 392.
additive compounds of, with aromatic nitrogen compounds (Mas- carelli), A., ii, 182.
pastilles, rapid valuation of (Flora), A., ii, 735.
detection of very small quantities of (Kof and Haehn), A., ii, 69.
estimation of, in pastilles (Saporetti), A., ii, 183; (Rimini), A., ii, 433.
ammonium chloride (white precipitate), reactions of, with methyl iodide (Schmidt and Krauss), A., i, 139.
acidimetric assay of (Rupp and Lehmann), A., ii, 70.
iodide, two observations relating to the decomposition of (Kohn), A., ii, 696.
action of, on ketones in alkaline solution (Marsh and Struthers), P., 266.
double salt of, with potassium iodide in organic solvents (Marsh and Struthers), P., 266.
nitrate, action of, on inorganic hydroxides (Biltz and Zimmer- mann), A., ii, 104.
nitrate solution, solubility of silver chloride in (Buttle and Hewitt), T., 1405; P., 173.
Mercury:

Mercuric oxide, estimation of, volumetrically (Rupp and Schirmer), A., ii, 1073.

sulphide, solubility of (Knox), A., ii, 830.

Mercuri-iodides of aluminium and thorium (Duboin), A., ii, 593.

Mercury organic compound, new (Nardelli), A., ii, 715.

Mercury cyanides, complete analysis of (Rupp and Lehmann), A., ii, 70.

oxycyanide, acidiometric estimation of both mercury components in (Rupp), A., ii, 634.

Mercuric cyanide, preparation of (Rupp and Goy), A., i, 863.

reactivity of (Hofmann and Wagner), A., i, 143, 514.

compounds of, with alkalis and nitric acid (Hofmann and Wagner), A., i, 514.

alkaline, action of, on halogen derivatives of acetylene and ethylene (Hofmann and Kirmreuther), A., i, 145.

compound of, with pyridine (Schroeder), A., i, 252.

zinc cyanide, formula of (Dunstan), P., 135.

oxycyanide (Rupp and Goy), A., i, 770.

Mercury dialkyls and sodium, action of a mixture of, on aldehydes, ketones, esters, and carbon dioxide (Schorigin), A., i, 881.

diethyl, action of, on mercury fulminate (Grigorowitsch), A., i, 251.

phenyl, reaction of, with zirconium tetrachloride (Peters), A., i, 1032.

Cyanomercury salts (Borelli), A., i, 515.

Mercuri-fatty acids, a-hydroxy-, synthesis of (Schrauth and Schoeller), A., i, 617.

Mercuriacetic anhydride, hydroxy-, and its salts, synthesis of (Schrauth and Schoeller), A., i, 617.

Mercuridimalonic acid, methyl ester (Schrauth and Schoeller), A., i, 617.

Mercury, estimation of, by reduction with hydrogen peroxide (Kolb and Feldhofer), A., ii, 69.

vapour, new method of estimating, in air (Meniere), A., ii, 433.

estimation of, volumetrically, by the thio cyanate, iodometric, and acidi metric processes (Rupp), A., ii, 1073.

Mercury, estimation of, volumetrically, in its ores (Muller), A., ii, 227.

Mercury measuring tubes. See under Analysis.

Merotropic compounds, phenylcarbimide as reagent for determining the constitution of (Michael and Cobb), A., i, 947.

Merotropy and desmotropy (Michael and Smith), A., i, 943; (Michael and Cobb), A., i, 947.

Mesaconic acid, phenyl esters, and their derivatives (Clarke), A., i, 333.

Mesityl oxide (methyl isobutyl ketone, isopropylidenacetone), aminopyrrolidine derivatives from (Kohn), A., i, 829.

Mesitylenesulphinic acid, preparation of (Knoevenagel and Kenner), A., i, 971.

Mesitylenesulphinic anhydride, preparation of (Knoevenagel and Polack), A., i, 971.

Mesitylenetraldehyde (1:3:5-trimethylalbenzene) and its hexa-acetate (Bielecki), A., i, 424.

Mesityloxidoxalic acid, methyl esters, polymeride of, rotary polarisation in crystals of (Sommerfeldt), A., ii, 339.

Mesohdy, so-called (Auwers), A., i, 228.

Mesolite from Montresta, Sardinia (Pelacani), A., ii, 864.

Mesothorium (Hahn), A., ii, 557.

short-lived intermediate product between radiothorium and (Hahn), A., ii, 454.

Mesoxalic acid, methyl ester, and some of its reactions (Curtiss and Tarnowski), A., i, 760.

Metabolism, effect of castration on (McCrudden), A., ii, 405.

action of intestinal astringents on (Spiro), A., ii, 1050.

influence of magnesium sulphate on (Steel), A., ii, 767.

changes in, due to the action of strontium (Burgass), A., ii, 405.

in acapanuria (Abderhalden and Bloch), A., ii, 54.

in a case of coma under rectal feeding (Laidlaw and Ryffel), A., ii, 311.

animal, the importance of so-called plant-amides in (Henriques and Hansen), A., ii, 119.

of calcium (Patterson), A., ii, 205.

of calcium, magnesium, and phosphorus during inanition (Wellsmann), A., ii, 306.

in relation to rickets (Aron), A., ii, 771.
INDEX OF SUBJECTS.

Metabolism, creatinine (LEFMANN), A., ii, 1050.
gaseous, changes in, after exclusion of hepatic circulation (SCAFFIDI), A., ii, 1051.
in uremic dogs (LA FRANCA), A., ii, 303.
inorganic and nitrogenous, in pancreatic diabetes in dogs (ELTA and WHITNEY), A., ii, 213.
intermediary, influence of thyroidectomy and thyroid feeding on (UNDERHILL and SAIKI), A., i, 962.
of the dog, influence of hydrazine on (UNDERHILL and KLEINER), A., ii, 214.
mineral, in healthy and rachitic children (CRONHEIM and MÜLLER), A., ii, 405.
nitrogenous parenteral (MICHAELIS and RONA), A., ii, 206.
nuclein, in a dog with an Eck's fistula (SWEET and LEYENE), A., ii, 119.
ferments of (SCHITTENHELM), A., ii, 960.
phosphorus, in man (SHERMAN), A., ii, 405.
of proteins, immunity, and hypersensitiveness (FRIEDEMANN and ISAAC), A., ii, 606.
and muscular activity (SHAFFER), A., ii, 961.
influence of amides on (FRIEDLÄNDER), A., ii, 514.
influence of carbohydrates on (MARLIN), A., ii, 306.
influence of internal hemorrhage on (WEINGARTEN and CROHN), A., ii, 710.
influence of potassium cyanide on (RICHARDS and WALLACE), A., ii, 214.
in cystinuria (WOLF, SHAFFER, ÖSTERBERG, and SOMOGYI), A., ii, 717.
in poisoning by bromobenzene (MARriott and WOLF), A., ii, 123.
respiratory. See Respiratory metabolism.
starvation (HALPERN), A., ii, 1051.
uric acid, the importance of allantoin in (WIECHOWSKI), A., ii, 119.

Metachlorophyllin. See Chlorophyll, so-called crystalisable.

Metal ammonia compounds, complex (WERNER), A., ii, 42; (WERNER, BINDSCHEDLER, and GRÖN), A., ii, 43; (SAND and BÖRMAN), A., ii, 44.
See also under the separate Metals.

Metallic carbonates and hydroxides, free energy changes attending the formation of certain (JOHNSTON), A., ii, 812.
dissociation pressures of some (JOHNSTON), A., ii, 358; (SCHOTTKY), A., ii, 1016.
See also Carbonates.
cyanides, reactions of, with phenylhydrazine (STRUTHERS), P., 179.
See also Cyanides.
deposits, use of, in metallography (GIOLITTI), A., ii, 945.
films, transparent (TURNER), A., ii, 1034.
halogen salts, oxides, and sulphides, action of metallic calcium and calcium hydride on (PERKIN and PRATT), A., ii, 379
See also Perhalogen salts.
hydroxides and carbonates, free energy changes attending the formation of certain (JOHNSTON), A., ii, 812.
dissociation pressures of some (JOHNSTON), A., ii, 358; (SCHOTTKY), A., ii, 1016.
amphoteric (WODD), T., 411; P., 15.
preparation of hydrosols of, from hydrogels (MÜLLER), A., ii, 286.
action of, on solutions of ammonium thiocyanate (GROSSMANN), A., i, 512.
action of silver nitrate and of mercuric nitrate on (BLITZ and ZIMMERMANN), A., ii, 104.
ions. See Ions under Electrochemistry.
nitrides, formation of (HENDERSON and GALLETTY), A., ii, 485.
and their magnetic properties (SHUKOFF), A., ii, 484; (WEDEN and VEIT), A., ii, 1041.
See also Nitrides.
oxides, emission of electrons by (JENTSCH), A., ii, 652.
reduction of, by carbon, in presence of metallic iron and other substances (GREENWOOD), T., 1496; P., 189.
autoreduction of some, in the vacuum of the cathode light (DAMM and KRAFFT), A., ii, 39.
action of, on primary alcohols (SABATIER and MAILHE), A., i, 594, 715.
refractory, reduction of, by carbon (GREENWOOD), T., 1483; P., 188.
See also Oxides.
radiation. See under Photochemistry.
radicles, oxygenated, magnetic properties of (PASCAL), A., ii, 1013.
Metallic salts, specific heat of, between the temperature of liquid air and room temperature (Nordmeyer), A., ii, 358.

equilibrium between metals and solutions of (bose), A., ii, 569.

action of arsenic on solutions of some (Reckleben, Lockemann, and Eckardt), A., ii, 36.

as peroxides (wolff), A., i, 137, 490; ii, 573, 1022; (wolff and de Stokklin), A., ii, 746.

reactions of, with phenylhydrazine (struthers), P., 179.

cyclic complex, new class of (grün and Bockisch), A., i, 984.

fused, influence of temperature and of the state of aggregation on the absorption spectra of (retschinsky), A., ii, 910.
molecular state of (lorenz, kaufler, and liebmann), A., ii, 1023.

conductivity of (Arndt and gessler), A., ii, 923.

viscosity of, at high temperatures (Fawsitt), T., 1302; P., 146.

of the heavy metals, change of free energy accompanying the formation of (lorenz and fox), A., ii, 656.

densities of some, and their mixtures at various temperatures (lorenz, Frei, and jabs), A., ii, 156.

density and equivalent conductivity of (Arndt and gessler), A., ii, 923.

normal, action of (Hüber), A., ii, 28.

See also Salts.

silicates (Jordis), A., ii, 103, 492; (Jordis and hennis), A., ii, 291.

preparation of, by wet methods (Jordis), A., ii, 291; (Ulffers), A., ii, 592.

See also Alkali silicates and Silicates, solutions, aqueous, surface tension of dilute (heydweiller), A., ii, 356.

sulphates, compounds of, with antimony sulphate (Gutmann), A., ii, 503.

See also Sulphates.

sulphides, liquefaction and sublimation of certain (Biltz), A., ii, 845.

and their mixtures, freezing-point diagrams of (friedrich and Schoen), A., ii, 281.

volatility of some (Damm and Krafft), A., ii, 39.

Metallic sulphides and sodium peroxide, use of, for decomposing minerals and industrial products (Walton and Scholz), A., ii, 732.

See also Sulphides under Sulphur, and Polysulphides.

vapours, abnormal dispersion of (Schön), A., ii, 334.

Metallography, use of metallic deposits in (giolitti), A., ii, 945.

Metalloids, the metallic form of (jordis), A., ii, 98.

ultimate rays of the (de Gramont), A., i, 645.

Metals, resolution of the spectral lines of some, in a magnetic field (moore), A., ii, 138.

photochemical action of, in the dark (légrady), A., ii, 142.

radioactivity of, and the penetrating radiation from the earth (McLennan), A., ii, 648.

photographic action of (Sæland), A., ii, 789.

galvanic self-induction of (van de Venter and van Lummel), A., ii, 12, 558.

difference of potential and the stability of the alternating arc between (Guye and Bron), A., ii, 561, 755.

electrical resistance and expansion of (Broniewski), A., ii, 147.

cathode of electricity by (Kinsky), A., ii, 754.

cathodic pulverisation of in attenuated gases (Kohlschüter and Goldschmidt), A., ii, 457; (Fischer and Hännel), A., ii, 653, 800, 925; (Kohlschüter), A., ii, 799, 800, 925; (Walter), A., ii, 925.

material effects accompanying the passage of an electric current through solutions of, in liquid ammonia (Kraus), A., ii, 835.

certain phenomena exhibited by, on a Nernst glower (Mendenhall and Ingersoll), A., ii, 151.

new method of determining the melting point of (Shukoff and Kurbatoff), A., ii, 153.

relation between compressibility, thermal expansion, atomic heat, and atomic volume of (Grüneisen), A., ii, 568.

thermal expansion and specific heat of (Grüneisen), A., ii, 568.

passive state of (Byers), A., ii, 1026.

viscosity of (Fawsitt), T., 1306; P., 146.

viscosity of, certain, and its variation with temperature (Guye and Mintz), A., ii, 930.
Metals, diffusion of, in mercury (Smith), A., ii, 159.
equation of condition for; a correction (Grüneweisen), A., ii, 563; (Thiesen), A., ii, 659, 808.
application of the kinetic theory to (Reboul), A., ii, 934.
and solutions of metallic salts, equilibrium between (Bose), A., ii, 569.
solutions of, in non-metallic solvents (Kraus), A., ii, 486, 834, 835.
hardness of solid solutions of (Kurnakoff and Schemtischuschny), A., ii, 932.
finely divided, action of, on nitrogen compounds (Padao and Chiaves), A., i, 104.
catalytic action of, on compounds containing nitrogen (Padao and Scaglariini), A., i, 828.
action of, on water (van Ryn), A., ii, 190.
behaviour of, when heated in ammonia (Henderson and Galletly), A., ii, 485.
action of ammonium persulphate on (Turrentine), A., ii, 104; (Levi, Migliorini, and Ercolini), A., ii, 581.
action of halogens on (Schuyten), A., ii, 51, 685.
action of nitric acid on (Stansbie), A., ii, 497.
action of oxygen on (Jordis and Rosenhaupt), A., ii, 172.
action of, on aqueous solutions of the persulphates (Turrentine), A., ii, 104; (Levi, Migliorini, and Ercolini), A., ii, 581.
extraction of gases contained in (Boudouard), A., ii, 109.
and ammonia, formation of compounds between (Kraus), A., ii, 486.
the rapid electro-analytical deposition and separation of (Sand), T., 1572; P., 189.
qualitative and quantitative separation of (Pozzi-Escot), A., ii, 892.
which are precipitated by hydrogen sulphide, separation of the (Bollenbach), A., ii, 985.
Metals of the ammonium sulphide group, separation of (Euler), A., ii, 987.
Metanil yellow as a selective indicator (Lindele), A., ii, 627.
Metasaccharin, C2 sugars from (Kilian), A., i, 185.
Metastannic acid. See under Tin.

Meteloidine from Datura Meteloides and its additive salts (Pyman and Reynolds), T., 2077; P., 234.
Meteoric chromites (Tassin), A., ii, 956.
iron, El Inca (Rinne and Boeke), A., ii, 303.
Meteorite, Ainsworth (Howell), A., ii, 204.
Allegan, calcium sulphide in the (Tassin), A., ii, 956.
Jerseyite (Goldsmith), A., ii, 401.
Williamstown (Howell), A., ii, 203.
Methane, synthesis of (Bone and Coward), T., 1975; P., 222.
synthesis of, by means of calcium hydride (Mayer and Altmayer), A., i, 845.
thermal decomposition of (Bone and Coward), T., 1197; P., 167.
action of the silent electric discharge on moist (Lön), A., i, 117.
derivatives in which two or three atoms of hydrogen are replaced by negative radicles (Haller and Muller), A., ii, 445, 1001.
Methane, dibromomido-, bromodiido-, and chlorodiido- (Auger), A., i, 494.
trichloro-. See Chloroform.
See also Marsh gas.
Methanesulphonic acid, chlorobromostyrylamine and quinidine salts, and their optical activity (Pope and Read), T., 797; P., 99.
Methanetricarboxylic acid, thioanilide and thioallylamide, diethyl esters and diamides of (Ruhemann), T., 623; P., 53.
diethyl ester, thioanilide of, action of ethyl chloroacetate on (Ruhemann), T., 627; P., 53.
3-Methoxyacetophenone, 4-hydroxy-. See Apocynin.
Methoxyacetylphosphamic acid, dibromo-, methyl ester (Steinkoff and Grünupp), A., i, 962.
Methoxyanthraquinone, dehydroxy- (Bentley and Weizmann), T., 437; P., 52.
p-Methoxyastrolactic acid and atrolic acid, comparative study of the dehydration of (Bougaullt), A., i, 340.
p-Methoxyastrabetic acid and its dibromide (Bougaullt), A., i, 341.
4-Methoxybenzaldehyde, 2-and 3-chloro-, synthesis of (Gattermann), A., i, 31.
1-Methoxybenzene. See Anisole.
p-Methoxy-benzhydrylamine and its derivatives benzhydrol (Busch and Lehrhein), A., i, 153.
p-Methoxybenzoic acid. See p-Anisic acid.
2-Methoxybenzoic acids, nitro-, isomeric (Keller), A., i, 285.

Methoxybenzonitrile, dinitro-, van Genus', constitution of (Blanksa), A., i, 271.

5-Methoxybenzophenone, 2-hydroxy- (Herzig and Hofmann), A., i, 190.

Methoxy-α-benzoquinone, tribromo-, methylhemiaceatal of, and its acetyl derivative and phenylhydrazone (Jackson and Flint), A., i, 191.

1-p-Methoxybenzylcoumarone (Zwayer and v. Kostanecki), A., i, 444.

4-Methoxybenzylpropionic acid, 2-hydroxy-, and its methyl ester, preparation of (Perkin and Robinson), T., 508.

2-Methoxybenzylideneacetyl-1-naphthol (v. Kostanecki), A., i, 359.

p-Methoxybenzylideneamine-α-alkylcinnamic acids, esters, and their liquid crystals (Vorlander and Kasten), A., i, 641.

p-Methoxybenzylidenemethylsemicarbazide (Michaelis and Hadanck), A., i, 1020.

2-Methoxybrazan (v. Kostanecki and Lampe), A., i, 672.

5-Methoxybutane-α-αγ-tetraoxybenzyl acid and its ethyl ester and silver salt, synthesis and hydrolysis of (Simonse, T., 1784.

3-Methoxy carbazole and its piperate (Borsche, Witte, and Bothe), A., i, 368.

4-Methoxychalkone, 2-hydroxy-, and its sodium salt and acetate, and dibromide of the acetate (Zwayer and v. Kostanecki), A., i, 444.

p-Methoxy cinnamaldehyde, liquid crystals of (Rotarski), A., i, 641.

p-Methoxy cinnamaldehyde, presence of, in oil of tarragon, and its oxime and semicarbazone (Daufresne), A., i, 19; (Daufresne and Flament), A., i, 558.

p-Methoxy cinnamic acid, liquid crystals of (Rotarski), A., i, 640.

5-Methoxy diethyl phthalaldehyde, 4:6-di- amino-, and its diacetyl derivative (Bauer), A., i, 274.

Methoxy dihydrodicyclopentadiene, nitro- (Rule), T., 1562; P., 175.

and its reactions (Wieland and Stenzl), A., i, 519.

4-Methoxy-3:5-dimethylbenzaldehyde, synthesis of (Gattermann), A., i, 33.

4-Methoxy-2:6-dimethylbenzaldehyde and its oxime, synthesis of (Gattermann), A., i, 33.

4-Methoxy-3:5-dimethylbenzophenone (Auwers and v. Markovits), A., i, 630.

6-Methoxy-2:4-dimethylpyridine, 3-cyano- (V. Meyer and Henning), A., i, 911.

Methoxydicyclopentadiene, compound of, with platinous chloride (Hofmann and v. Narbut), A., i, 519.

1-Methoxy-3-ethoxybenzene, 2:6-di- and 2:4:6-trinitro- (Blanksa), A., i, 158.

Methoxyethoxy-N-ethylisouquinolone (Decker and Dunant), A., i, 206.

Methoxyethoxymethane (Henry), A., i, 381.

Methoxyethoxy-2-methylbenzaldehyde and its oxime, synthesis of (Gattermann), A., i, 34.

Methoxyethoxy-N-methylisouquinolone (Decker and Dunant), A., i, 206.

Methoxyl groups, detection of (Herzig), A., ii, 638.

quantitative estimation of (Kirpal), A., ii, 436.

elimination of the (v. Kostanecki and Lampe), A., i, 442.

5-Methoxy-Δ2-hexene (Reif), A., i, 847.

p-Methoxyhydratropylypyruvic acid, iodo-lactone from (Bougault), A., i, 539.

2-Methoxyindene, 3-cyano- (Moore and Thorpe), T., 180; P., 18.

7-Methoxy-2:3-indenobenzopyranol(1:4), anhydroferrichloride (Perkin and Robinson), T., 1102.

7-Methoxy-4:3-indenobenzopyranol(1:4), 4:5'-dihydroxy-, salts of (Engels, Perkin, and Robinson), T., 1150.

4-Methoxy-1-indoxyl benzene and its sulfonic acid (Friedlander and Schuloff), A., i, 674.

3-Methoxy-1-methyl-4-ψ-allylbenzene and its polymeride (Béhal and Tiffeneau), A., i, 631.

6-Methoxy-2-methyl benzaldehyde, 4-hydroxy-, and its azine, oxime, and phenylhydrazone (Gattermann), A., i, 31.

p-Methoxy-Ø-methylcinnamic acid (Schroeter and Buchholz), A., i, 170.

5-Methoxy-2-methylcoumarilic acid and its methyl and ethyl esters (v. Kostanecki and Lampe), A., i, 442.
INDEX OF SUBJECTS.

1369

7-Methoxy-5-methylflavone (TAMBOR), A., i, 350.
Methoxy-7-methylflavones, 2', 3', and 4', 5-hydroxy-, and their sodium salts (TAMBOR), A., i, 358.
α-Methoxymethylglutaric acid and its barium salt (SIMONSEN), T., 1783.
β-Methoxymethylmalonic acid, ethyl ester, synthesis and reactions of (SIMONSEN), T., 1780; P., 212.
β-Methoxymethyl-β-isopropylmalonic acid and its ethyl ester and barium salt, synthesis of (SIMONSEN), T., 1787; P., 212.
β-Methoxymethylisovaleric acid and its ethyl ester and silver salt, synthesis of (SIMONSEN), T., 1788.
Methoxy-a-naphthflavanones, 3'- and 4'-, and their isonitroso-derivatives (V. KOSTANECKI), A., i, 359.
Methoxy-a-naphthflavonols, 3'- and 4'-, and their sodium salts and acetates (V. KOSTANECKI), A., i, 359.
1-Methoxy-2-naphthaldehyde (FRIEDLÄNDER), A., i, 373.
4-Methoxy-2-naphthaldehyde, 1-hydroxy- (FRIEDLÄNDER), A., i, 373.
Methoxy-1-naphthaldehydes, 2- and 4-, and their amines, synthesis of (GATTERMANN), A., i, 38.
2-Methoxy-1-naphthylcarbinyl-amine and -chloroacetamide (EINHORN), A., i, 613.
γ-Methoxyphenylenaminoacetoacetic acid, ethyl ester (BENARY), A., i, 601.
4-Methoxy-2-phenylbenzopyranol(1:4) salts (PERKIN, ROBINSON, and TURNER), T., 1111.
3-Methoxyphenylmethylcarbinol, 4-hydroxy-. See APOCYNOL.
4-p-Methoxyphenyl-6-phenyl-2-methylpyridine, 3-cyano- (V. MEYER and LAMSCHER), A., i, 911.
4-Methoxyphenylphthalide, 2-hydroxy- (PERKIN and ROBINSON), T., 611.
β-Methoxynonyphenylpropaldehyde and its dimeric form, preparation of (BALSIANO), A., i, 901.
γ-p-Methoxynonyphenylpropane-αβ-diol (DAUPRESNE), A., i, 19.
p-Methoxyphenyl-. See also Anisylic.
α-Methoxy-n-propyl iodohydrin (HOERING), A., i, 896.
α-Methoxystyrene (TIFFENNEAU), A., i, 19.

XCIV. ii.

9-Methoxy-Δ1(9)-tetrahydrocarbazole (BORSCHE, WITTE, and BROTHE), A., i, 366.
5-Methoxythionaphthen, tri- and tetra-chloro- (WARGER and EWINS), T., 2089.
Methoxylinaldehyde and their derivatives, synthesis of (GATTERMANN), A., i, 32.
p-Methoxytoluene, α-dinitro-, diazo-benzene derivative (PONZIO and CHARRIER), A., i, 582.
p-Methoxytoluene-m-sulphonic acid and its oxidation (SMILES and LE ROSSIGNOL), T., 758.
m-Methoxytolyl sulphoxide (SMILES and LE ROSSIGNOL), T., 756.
p-Methoxytolyl sulphoxide (SMILES and LE ROSSIGNOL), T., 759.
3-Methoxytritanic acid, 4-hydroxy- (V. LIEBIO), A., i, 541.
a-Methoxytritanol-3-sulphonic acid, ammonium salt (V. LIEBIG and HERB), A., i, 450.
5-Methoxy-m-xylene-2-sulphonic acid (SMILES and LE ROSSIGNOL), T., 761.
5-Methoxy-m-xylyl sulphoxide (SMILES and LE ROSSIGNOL), T., 761.
Methronic acid, constitution of (TREPHILIEFF), A., i, 735.
bromo-derivatives, constitution of (TREPHILIEFF), A., i, 735.
Methyl alcohol, condensation of, with benzoin (IRVINE and MCNICOLL), T., 950; P., 119.
conversion of, into formaldehyde (ORLOFF), A., i, 77, 761.
and its impurities (FRIEDRICH), A., ii, 990.
detection of small quantities of, in presence of ethyl alcohol (HINKEL), A., ii, 1076.
detection of, in fermented liquids (WOLFF), A., ii, 72.
Methyl chloride, physical properties of (BAUME), A., ii, 372.
cyanide, preparation of (AUGER), A., i, 81.
derivatives, volatility in the "methylation" series of (HENRY), A., i, 381.
Methyl ether, physical properties of (BAUME), A., ii, 372.
Methyl ether, chloro-, action of, on magnesium phenyl bromide (KEYCHLER), A., i, 159.
action of, on the phenoxides of the alkali metals (KEYCHLER), A., i, 158.
syntheses with (SIMONSEN), T., 1777; P., 212.
Methyl ether, hydroxy-, preparation of (Reychler), A., i, 130.

Methyl silicate, latent heat of vaporisation and specific heat of (Kahlenberg and Koenig), A., ii, 460.

Methyl sulphate, preparation of (Societe Anonyme des Produits Chimiques de Fontaines in Lyon-Monplaisir), A., i, 597.

action of, on alkali polysulphides (Strecker), A., i, 386.

action of, on oils of the aromatic and aliphatic series (Harrison and Perkin), A., ii, 135.

and oil of turpentine, reciprocal solubility of (Dubroca), A., ii, 22.

Methyl sulphate, chloro-, action of aminogroups on (Houben and Arnold), A., i, 533.

Methylacetal. See Acetilmethylcarbinol.

Methylacetone. See Methyl ethyl ketone.

α-Methyldipic acid, esters and diamide of (Bouyeault and Locquin), A., i, 172.

α-Methylallyl alcohol. See Δα-Buten-γ-ol.

4-Methyl-3-isoamylsalicylic acid and its dibromide (Meerwein), A., i, 90.

Methylamine, two methods of preparing (Francois), A., i, 506, 765; (Berthoume), A., ii, 742.

modification of the preparation of, from bromoacetamide (Francois), A., i, 956.

magnesium phosphate (Francois), A., i, 505.

Methylamines, detection of, in presence of ammonia (Tsalapatin), A., ii, 440.

p-Methylaminobenzaldehydehydrazine, liquid crystals of (Rotarski), A., i, 640.

2-Methylaminobenzoic acid. See N-Methylanthranilic acid.

4-Methylaminobenzoic acid, 3-nitro-, methyl ester, 3:5-dinitro-, and its methyl ester, and 3:5-dinitro-ω-nitro- and 3:5-dinitro-ω-nitroso-, methyl esters (Reverdin and de Luc), A., i, 167.

Methilaminobenzoic acids, m- and p-, ω-cyano- (Houben and Arnold), A., i, 554.

Methilaminodimethylcarbinol and its divaleryl derivative (Riedel), A., i, 957.

4-Methylamino-5-ethoxy-1-phenyl-3-methylpyrazole, cyano- (Fahrwerke Vorm. Meister, Lucius, & Bruning), A., i, 472.

β-Methilamino-α-hydroxyisobutyric acid and its ethyl ester (Les Etablissements Poulenc Freres & Ernest Fourneau), A., i, 988.

Methylaminoketo. See Ketomethylamino.

2-Methylamino-3-methoxybenzoic acid (damascenic acid) (Keller), A., i, 234.

β-Methylamino-β-methylpentane, δ-amin-, and its additive salts and cyclic carbamide (Kohn and Morgenstern), A., i, 769.

2-Methylaminophenetole, 3-nitro- (Blanksma), A., i, 978.

p-Methylaminophenol, sulphurous acid compound of (Societe Anonyme des Plaques et Papiers photographiques, A. Lumiere et ses Fils), A., i, 977.

Methylaminophenylmethylcarbinol and its benzoyl derivatives (Riedel), A., i, 957.

o-Methylaminophenyl-o-toluidinoacetic acid (v. Ostromissensky), A., i, 82.

β-Methilaminopropaldehyde diethylacetate (Wohl and Johnson), A., i, 49.

γ-Methilamyl alcohol. See Hexyl alcohol, active.

Methilamylsalicylic acid. See δη-Dimethyl-δ-octen-8-ol.

δ-Methyl-Δα-amyline, β-chloro- (Clarke), A., i, 594.

Methilylaniline picrate (Vignon and Evieux), A., ii, 665.

β-Methilaniminoethyl ethyl ketone and its picrate and semicarbazone (Blaise and Maire), A., i, 566.

α-Methilanthracene from emodin from aloes (Oesterle and Tisza), A., i, 905.

β-Methilanthracene from emodin from Frangula (Oesterle and Tisza), A., i, 356.

N-Methilanthranilic acid, 3- and 5-amino-, hydrochlorides of, and 5-chloro- (Keller), A., i, 284.

3-hydroxy-, and its hydrochloride (Keller), A., i, 284.

5-nitroso- (Houben and Brassert), A., i, 27.

Methilanthraquinone, dihydroxy-derivatives. See Morindadiol and Soran-jiadiol.

1-Methilanthraquinone, 2- and 4-chloro- (Heller and Schulke), A., i, 995.

Methylyarsinic acid, action of alkalis on, and its iodo-derivatives (Auger), A., i, 516.
diiodo- (Auger), A., i, 13.
Methylation in the ethylene derivatives from the point of view of volatility (Henry), A., i, 752.
Methylazulino-benzoic acid (Keller), A., i, 284.
Methylbaptigenetin and its acetylation (Gorter), A., i, 98.
Methylbenzanthrone, preparation of (Badische Anilin- & Soda-Fabrik), A., i, 993.
p-Methylbenzhydryl-acetyl- and benzoyl-acetones (Fosse), A., i, 86.
Methylbenzyldilamine and its hydrochloride and nitrate (Busch and Leefhelm), A., i, 153.
Methylbenzylpyrazolone (Milrath), A., i, 1014.
Methyl isobutenyl ketone. See Mesityl oxide.
Methylisobutyliso-allylcarbinol. See α-Dimethyl-α-β-hepten-5-ol-.
Methylcyclobutylcarbinol and its phenylurethane (Zelinsky and Guttt), A., i, 618.
Methyl-β-butyleny α-β-oxide (Riedel), A., i, 956.
Methyl tert.-butyl ketone. See Pinacoln.
Methyl cyclobutyl ketone and its semicarbazone (Zelinsky and Guttt), A., i, 618.
α-Methylbutyric acid, l-amino- (isoulicine) (Ehrlich and Wendel), A., i, 269.
Methyamicophilenonitrile (Glover), T., 1299; P., 152.
α-Methaclymphor, preparation of, and its bromo-derivatives and β-sulphonic acid and its derivatives, and oxime (Glover), T., 1299; P., 151.
comparison of, with fenchone (Glover), T., 1285; P., 151.
Methylicarbamide cyanocacetate (Baum), A., i, 252.
Methylicarbamides, action of, on benzil (Biltz, Horrmann, and Rimpel), A., i, 218; (Biltz and Rimpel), A., i, 462.
Methylcarbazole and its piorate (Borsche, Witte, and Bothe), A., i, 307.
p-Methyl-carbonatobenzoic acid and its chloride (Fischer), A., i, 592.
p-Methyl-carbonatobenzoylglucine, ethyl ester (Fischer), A., i, 892.
Methyl-carbonato-derivatives of amino- acids (Fischer), A., i, 544.
2-Methylisocarbostyril-4-carboxylic acid and its ethyl ester (Dieckmann and Meiser), A., i, 895.
2-Methylcarvenene (Ruhe and Emmerich), A., i, 556.
Methyldichlorodiacetamide (Bergell and Feigl), A., i, 141.
Methyl α-chloropropyl ketone, preparation of (Korschun), A., i, 502.
4-Methyl-1-chloropropylfuracic acid (Majima), A., i, 223.
Methylcinchotoxine methiodide and its benzoyl derivative (Rabe, Schneider, and Braasch), A., i, 361.
4-Methyl-o-coumaric acid, ethyl ester (Fries and Klostermann), A., i, 822.
2-Methylccumaric acid, and 4-mono-and 4:6-dil-bromo-, and their salts (Peters and Simonis), A., i, 340.
4-Methylcumarin and its bromo-derivatives (Peters and Simonis), A., i, 339.
6- and 7-chloro-, formation of (Clayton), T., 2021.
7-Methylocumarin and its additive salts, oxime, and phenylhydratone (Clayton), T., 526; P., 26.
3-Methylytosine and its piorate and platinichloride (Johnson and Clapp), A., i, 836.
4-Methylytosine, synthesis of, and its additive salts (Johns), A., i, 917.
Methyl damascenine and its additive salts and nitroso-compound (Keller), A., i, 263.
2-Methyl-1:2'-dianthraquinonylamino, oxidation of (Badische Anilin- & Soda-Fabrik), A., i, 466.
Methyldiethylnolamine, chloro-, and its platinichloride (Houben and Arnold), A., i, 534.
2-Methylidihydrocarvene. See 2-Methyl homolinonene.
2-Methylidihydrocarvenol (Ruhe and Emmerich), A., i, 433.
4-Methylidihydrocumarin (Peters and Simonis), A., i, 340.
α-Methyl-dihydrogeranic acid. See αβ-Trimethyl-α-β-ocetoenoic acid.
2-Methylidihydroquinoline and its piorate (Heller and Sourlis), A., i, 914.
Methylidihydrouracil, α and β, trihydroxy-, and their reactions (Behrend and Beer), A., i, 840.
1-Methylcyclo-1:2:3-Δ'octen-3-one (Semmler and Bartelt), A., i, 355.
4-Methylidenylamine, 4-nitro-3-amino- (Ullmann), A., i, 457.
4-Methylidenylmethanecarboxylic acid, 2-hydroxy-, lactone of (V. Leibig), A., i, 728.
Methylenecyclobutane. See Vinyltrimethylene.

Methylenecitric acid, preparation of (Farbenfabriken vorn. F. Bayer & Co.), A., i, 604.

Methylenecitric acid, preparation of (Farbenfabriken vorn. F. Bayer & Co.), A., i, 631.

Methylenedicyclohexylamine, conversion of, into carbonyldicyclohexylamine (Barger), T., 566.

Methylenedicyclohexylamine, preparation of (Hoering), A., i, 895.

4:5-Methylenedicyclohexylamine (1:4) anhydroferrichloride (Perkin and Robinson), T., 1105.

γ-Methylenedicyclohexylammonium acid, β-iodo-α,α-dihydroxy-, lactone of (Bougafult), A., i, 539.

γ-Methylenedicyclohexylammonium acid, α-hydroxy- (Bougafult), A., i, 270.

Methylenedicyclohexylammonium acid and its iodolactone (Bougafult), A., i, 270.

α-3:4-Methylenedicyclohexylammonium ethyl-ether, β,β-dichloro-, αβωω-tetrachloro-, and β-chloro-α-hydroxy- (Barger), T., 2083; P., 237.

β-3:4-Methylenedicyclohexylammonium methylamino, β-hydroxy-, and its benzoyl derivative and their additive salts (Pyman), T., 1806; P., 208.

α-3:4-Methylenedicyclohexylammonium propyl-ether, αβωω-tetrachloro- (Barger), T., 2085; P., 237.

INDEX OF SUBJECTS.

5-3:4 Methylenedicyclohexylammonium valeric acid, β-iodo-γ-hydroxy-, lactone of (Bougafult), A., i, 537.

3:4-Methylenedicyclohexylammonium, ω-bromo-dinitro- and ω-chloro-dinitro- (Ponzi and Charrier), A., i, 522.

Methylenedicyclohexylammonium, its dibromide, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.

Methylenedicyclohexane and its dibromide, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.

Methylenedicyclohexene and its dichloride, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.

Methylenechloride, condensation of, with 1-bromo- and 1-chloro-2-naphthylamines (Senier and Austin), T., 63.

Methyleneaminobenzoic acids, m- and p- (Houben and Arnold), A., i, 534.

Methyleneaminobenzoic acid and its salts (Houben and Arnold), A., i, 533.

Methylenedecimethylcarbamides, α-ethylbutyramide, -ethylcarbamide, and -propionamide (Einhorn), A., i, 609.

Methylenedimethylidianthranilic acid (Houben and Arnold), A., i, 533.

Methylenedimethylamine, derivatives of (Gneim and Walder), A., i, 63.

Nitro- See Methylene-green.

Methyleneethylamine, See Vinyltrimethylene.

Methylenecyclobutane. See Vinyltrimethylene.

Methylenecitric acid, preparation of (Farbenfabriken vorn. F. Bayer & Co.), A., i, 604.

Methylenecitric acid, preparation of (Farbenfabriken vorn. F. Bayer & Co.), A., i, 631.

Methylenedicyclohexylamine, conversion of, into carbonyldicyclohexylamine (Barger), T., 566.

Methylenedicyclohexylamine, conversion of, into carbonyldicyclohexylamine (Barger), T., 566.

Methylenedicyclohexylamine, preparation of (Hoering), A., i, 895.

4:5-Methylenedicyclohexylamine (1:4) anhydroferrichloride (Perkin and Robinson), T., 1105.

γ-Methylenedicyclohexylammonium acid, β-iodo-α,α-dihydroxy-, lactone of (Bougafult), A., i, 539.

γ-Methylenedicyclohexylammonium acid, α-hydroxy- (Bougafult), A., i, 270.

Methylenedicyclohexylammonium acid and its iodolactone (Bougafult), A., i, 270.

α-3:4-Methylenedicyclohexylammonium ethyl-ether, β,β-dichloro-, αβωω-tetrachloro-, and β-chloro-α-hydroxy- (Barger), T., 2083; P., 237.

β-3:4-Methylenedicyclohexylammonium methylamino, β-hydroxy-, and its benzoyl derivative and their additive salts (Pyman), T., 1806; P., 208.

α-3:4-Methylenedicyclohexylammonium propyl-ether, αβωω-tetrachloro- (Barger), T., 2085; P., 237.

5-3:4 Methylenedicyclohexylammonium valeric acid, β-iodo-γ-hydroxy-, lactone of (Bougafult), A., i, 537.

3:4-Methylenedicyclohexylammonium, ω-bromo-dinitro- and ω-chloro-dinitro- (Ponzi and Charrier), A., i, 522.

Methylenedicyclohexylammonium, its dibromide, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.

Methylenedicyclohexene and its dichloride, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.

Methylenedicyclohexene and its dichloride, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.

Methylenedicyclohexene and its dichloride, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.

Methylenedicyclohexene and its dichloride, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.

Methylenedicyclohexene and its dichloride, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.

Methylenedicyclohexene and its dichloride, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.

Methylenedicyclohexene and its dichloride, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.

Methylenedicyclohexene and its dichloride, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.

Methylenedicyclohexene and its dichloride, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.

Methylenedicyclohexene and its dichloride, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.

Methylenedicyclohexene and its dichloride, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.

Methylenedicyclohexene and its dichloride, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.

Methylenedicyclohexene and its dichloride, chloronitrosite, and piperidine (Faworsky and Borgmann), A., i, 15.
INDEX OF SUBJECTS.

1. Methylcyclohexanol and its bromide (Paworsky and Borgmann), A., i, 15.

2. Methylcyclohexan-3- and -4-ol-4-n-butylfonic acids, ethyl esters (Wallach and Rentschler), A., i, 405.

3. Methylcyclohexan-4-ol-isobutyric acid, ethyl ester (Wallach and Churchill), A., i, 406.

4. cis-1-Methylcyclohexan-6-ol-3-carboxylic acid and its lactone (Fisher and Perkin), T., 1883.

5. trans-1-Methylcyclohexan-6-ol-3-carboxylic acid, synthesis of (Fisher and Perkin), T., 1882.

7. Methylcyclohexan-3-ol-3-propionic acid, ethyl ester (Wallach and Evans), A., i, 404.

8. Methylcyclohexan-4-ol-4-propionic acid (Wallach and Evans), A., i, 404.

10. Methylcyclohexan-3-one, condensation of, with ethyl α-bromopropionate (Wallach and Evans), A., i, 404.

11. Methylcyclohexan-4-one, condensation of, with ethyl α-bromopropionate (Wallach and Evans), A., i, 404.

13. Methylcyclohexan-2-, -3-, and -4-ones, condensation of, with ethyl α-bromoiso-butyratc (Wallach and Churchill), A., i, 406.

14. Methylcyclohexan-3- and -4-ones, condensation of, with ethyl α-bromo-n-butyratc(Wallach and Rentschler), A., i, 405.

15. Methylcyclohexan-2-one-4-carboxylic acid and its ethyl ester, oxime, and semicaparazone, preparation of (Meldrum and Perkin), T., 1425.

16. Methylcyclohexan-6-one-3-carboxylic acid and its oxime and semicaparazone, synthesis of (Fisher and Perkin), T., 1850.

17. Methylcyclohexan-3-one-nitrophenylhydrazone (Borsche, Witte, and Bothe), A., i, 367.

INDEX OF SUBJECTS.

1-Methyl-\(\Delta^1\)-cyclohexene and its chloronitrosite (Faworsky and Böhmann), A., i, 15.

1-Methyl-\(\Delta^3\)-cyclohexene-4-acetic acid and its ethyl ester and nitrile (Harding, Haworth, and Perkin), T., 1967; P., 230.

1-Methyl-\(\Delta^3\)-cyclohexene-4-acetic acid, \(\alpha\)-cyano-, and its ethyl ester (Harding, Haworth, and Perkin), T., 1963.

1-Methylcyclohexene-2-\(\beta\)-butyric acids and their ethyl esters and silver salts (Wallach and Rentschler), A., i, 405.

1-Methylcyclohexene-2-, 3-, and 4-iso-butyric acids and their derivatives (Wallach and Churchhill), A., i, 406.

1-Methyl-\(\Delta^6\)-cyclohexene-3-carboxylic acid and its calcium salt and ethyl ester, synthesis of (Fisher and Perkin), T., 1885; P., 228.

1-Methyl-\(\Delta^1\)-cyclohexene-4-carboxylic acid, formation of, from \(\alpha\)-cis- and \(\alpha\)-trans-1-methylcyclohexan-2-ol-4-carboxylic acids (Meldrum and Perkin), T., 1416; P., 187.

\(\alpha\)-1-Methyl-\(\Delta^1\)-cyclohexene-4-carboxylic acid, resolution of (Fisher and Perkin), T., 1871; P., 228.

\(\alpha\)-1-Methyl-\(\Delta^1\)-cyclohexene-4-propionic acid and its methyl ester and nitrile, and \(\alpha\)-cyano-, and its methyl ester (Harding, Haworth, and Perkin), T., 1973.

1-Methylcyclohexenopropionic acids and their ethyl esters and silver salts (Wallach and Evans), A., i, 404.

\(\beta\)-Methyl-\(\Delta^8\)-hexen-5-\(\beta\)-ol (Gry), A., i, 307.

\(\delta\)-Methyl-\(\Delta^8\)-hexen-\(\gamma\)-\(\beta\)-ol and its acetate (Abelmann), A., i, 2.

\(\gamma\)-Methyl-\(\Delta^8\)-hexen-5-\(\alpha\)-ol and its acetate (Reif), A., i, 847.

1-Methyl-\(\Delta^1\)(or 2)-cyclohexen-2-\(\beta\)-ol, acetate of (Mannich and Hancu), A., i, 276.

1-Methyl-\(\Delta^2\)-cyclohexen-4-\(\alpha\)-ol, acetate of (Mannich and Hancu), A., i, 276.

1-Methyl-\(\Delta^1\)-cyclohexen-2-\(\beta\)-ol-6-one (Blaise and Maire), A., i, 392.

1-Methyl-\(\Delta^1\)-cyclohexen-3-\(\alpha\)-4-6-dicarboxylic acid, ethyl ester, desmutropy of, and its sodium salt, \(p\)-nitrophenylhydrazone, and semicarbazone (Rabe, Spence, and Ehrenstein), A., i, 530.

\(\gamma\)-Methylhexic acid (Ciamician and Silber), A., i, 277.

\(\beta\)-Methylhexyl iodide (Zelinsky and Pscchevalsky), A., i, 845.

1-Methylcyclohexyl-4-acetic acid and its silver salt, and \(\alpha\)-bromo-, and its ethyl ester, and \(\beta\)-bromo-, and \(\alpha\)-hydroxy-, and its silver salt (Perkin and Pope), T., 1081.

4-bromo-3-hydroxy-, lactone of (Harding, Haworth, and Perkin), T., 1970.

1-Methylcyclohexyl-4-carboxil and its bromide (Perkin and Pope), T., 1078.

1-Methylcyclohexyl-3-hydrazine, formation of (Kijner), A., i, 106.

Methylycyclohexylhydrazone methylycyclohexanone (Kijner), A., i, 107.

1-Methylcyclohexylidene-4-acetic acid, experiments on the synthesis of, and its ethyl ester (Perkin and Pope), T., 1075; P., 145; (Harding, Haworth, and Perkin), T., 1943; P., 230.

2-Methylhomolinomene (2-methylidyhydrocarvene) and its hydrobromide (Kupe and Emmerich), A., i, 433.

N-Methylhomopapaververium derivatives (Decker and Dunant), A., i, 205.

Methylhomphathic acid, hydroxy-, methyl ester, \(\alpha\)- and \(\beta\)-m-nitrobenzoates of (Dieckmann and Meiser), A., i, 895.

Methylhydantoin, isomerism of (Harrisses), A., i, 573.

\(\beta\)-Methylhydantoin, preparation of (Weitzner), A., i, 841.

Methylhydrazine, acyl derivatives, constitution of (Michaelis and Hadanck), A., i, 1020.

\(\alpha\)-Methyl-\(\beta\)-hydridone, \(\alpha\)-cyano-, and its phenylhydrazine (Moore and Thorpe), T., 181; P., 19.

1-Methylhydrothymine, 5-bromo-4-hydroxy- and 5-nitro-4-hydroxy- (Johnson and Clapp), A., i, 886.

3-Methylhydrothymine, 5-nitro-4-hydroxy- (Johnson and Clapp), A., i, 886.

3-Methyl-1:7-\(\beta\)-di-hydroxydiethylxanthine (Farbenfabrikken Vorm. F. Bayer & Co.), A., i, 475.

5-Methyl-4-iminazolone, amino-, and its salts and methyl derivatives (Tafel and Mayer), A., i, 743.

2-Methylimino-4:6-dimethylidinepyrimidine (Majima and Kobayashi), A., i, 224.

\(\beta\)-Methyliminodipodaldehyde tetraethylacetal (Wohl and Johnson), A., i, 49.

Methylimino-groups, detection of (Herzig), A., ii, 638.
INDEX OF SUBJECTS.

1375

Methylimino-groups, quantitative estimation of (Kirpal), A., ii, 436.

5-Methylimino-1:2:3:tri-phenyl-cyclo-hexan-1:0:4-carboxylic acid, ethyl ester (Rabe and Ehrenstein), A., i, 553.

a-Methyl. See Glycerol monomethyl ether.

7-Methyldiazole and its nitroso-derivative, and the action of copper powder on (Jacobson and Huber), A., i, 299.

3-Methyldione (scotole), occurrence of, in the human intestine (Herter), A., ii, 211.

1-Methyldione (Carrasco), A., i, 913.

Methyl-dl-a-iodopropionyl-l-tryptophan (Aberdalden and Baumann), A., i, 932.

Methyl-2-ionone hydrate, preparation of (Coulon), A., i, 1000.

Methyliridic acid. See 3:4:5-Trimethoxyphenylacetic acid.

o-Methylin. See 1:2-Methylnaphthaquinolone, and its dihydrobromide and tetrabromide (Reif), A., i, 847.

1-Methyldicyclo-2:2:2:octane and 7-amino-, isomeric (Semmler and Bartelt), A., i, 38.

1-Methyldicyclo-2:2:2:octan-7:01 and its acetate and chloride (Semmler and Bartelt), A., i, 38.

Methylol compounds of acid amides (Einhorn, Feibelmann, Gütter, Hamburger, and Spröngerts), A., i, 608.

Methylolcarbamide (Einhorn and Hamburger), A., i, 142.

Methylolcarnol and its acetyl derivative (Power and Tutton), T., 899; P., 117.

Methylorange, isomerism of (Hantsch and Hilscher), A., i, 469.

a-Methyl-a-oxalosuccinic acid, ethyl ester, preparation and reduction of (Simonsen), T., 1783.

a-Methylmeconine, bromo- (Mermod and Simons), A., i, 343.

Methylmethyadiene (Rupe and Emmerich), A., i, 433.

3-Methyl-A-2:2:2:octane (Rupe and Ebert), A., i, 663.

2-Methylmenthane, 2:8-dihydroxy- (Rupe and Emmerich), A., i, 433.

Methylmenthatriene (Rupe and Emmerich), A., i, 433.

3-Methyl-A-8:8:8:8:octane (Rupe and Ebert), A., i, 663.

Methylmenthone (Arhusoff), A., i, 555.

1:2-Methylnaphthaquinonitrile, 3:monon-and 3:4-di-chloro (Fries and Hemplmann), A., i, 731.

1-Methyl-2-naphthaquinol, 3:monon-and 3:4-di-chloro (Fries and Hemplmann), A., i, 731.

1-Methyl(2:5)-dimethoxycarboxylic acid, ethyl ester, and its semicarbazones (Blanc), A., i, 21.

1-Methylpentane-3:4:one-3-acetic acid and its methyl ester, and their semicarbazones (Blanc), A., i, 172.
INDEX OF SUBJECTS.

1-Thymylcyclopentan-2-one-3-carboxylic acid, esters, and their semicarbazones (BOUVEAULT and LOCQUIN), A., i, 172.

Methylcyclopentan-4-one-3-carboxylic acid, methyl ester, and the reaction of the sodium derivative with ethyl bromoacetate (BLANC), A., i, 20.

2-Methylcyclopentanone-3-carboxylic acid and its ethyl ester, oxime, and semicarbazone, synthesis of (HAWORTH and PERKIN), T., 579.

2-Methylcyclopentanone-2,3-dicarboxylic acid, ethyl ester, and its hydrolysis (HAWORTH and PERKIN), T., 579.

2-Methylcyclopentanone-3,5-dicarboxylic acid, ethyl ester (HAWORTH and PERKIN), T., 582.

1-Methyl-α,δ- and δ-α'-pentene-2-carboxylic acids, formation and separation of, and oxidation of, and their ethyl esters (HAWORTH and PERKIN), T., 585.

Ethyl esters, action of magnesium methyl iodide on (HAWORTH and PERKIN), T., 593.

1-Methyl-α,δ,4-cyclopentene methyl ketone and its semicarbazone (HARDING, HAWORTH, and PERKIN), T., 1969.

γ-Methyl-α,γ-penten-β-ol and its acetate (ABELMANN), A., i, 2.

2'-Methyl-1,2:2'-phenonaphthacarbazole-N'-sulphonic acid, sodium salt (BUSCHER and SEYDE), A., i, 455.

4-Methylphenylmethylcarbinol, 2-hydroxy- (hydroxyethylmethyl) (FRIES and FICKEWIRTH), A., i, 824.

5-Methylphenylmethylcarbinol, 2-hydroxy- (FRIES and FICKEWIRTH), A., i, 824.

2-Methylpiperidine and water, mutual solubility of (FLASCHNER and MAC EWEN), T., 1000; P., 119.

Methylpiperidiumacetic acid, chloro-, and its ethyl ester and platinichloride (V. BRAUN), A., i, 608.

N-Methylproline. See Hygic acid.

1-Methyl-2-isopropenolcyclopentane, 5-hydroxy- (HAWORTH and PERKIN), T., 594.

1-Methyl-3-isopropenolcyclopentane, 1-hydroxy- (HAWORTH and PERKIN), T., 593.

1-Methyl-2-isopropenol-δ-cyclopentene (HAWORTH and PERKIN), T., 597.

1-Methyl-2-isopropenol- and -propenyl-δ-cyclopentenes (HAWORTH and PERKIN), T., 593.

1-Methyl-3-isopropenol- and -propenylcyclopentenes (HAWORTH and PERKIN), T., 592.

α-Methyl-α'-isopropyladipic acid, α'-di-hydroxy-, synthesis of (WALLACH and MEISTER), A., i, 812.

α-Methyl-δ-isopropyladipic acid and its ethyl ester (BOUVEAULT and LOCQUIN), A., i, 173.

3-Methyl-6-isopropylazobenzene, 4(2:4'-trinitro- (BORSHE), A., i, 68.

4-Methyl-1-isopropylcarbazole and its picrate (BORSHE, WITTE, and BOTHE), A., i, 367.

α-Methyl-α-isopropylidiglycollic acid, ethyl ester (JUNGFLEISCH and GONCHÖT), A., i, 128.

Methylisopropyldiphenyl-2-carboxylic acid and its silver salt (LUX), A., i, 874.

2-Methyl-5-isopropylhexahydrocarbazole and its nitroso- and carbamyl derivatives (BORSHE, WITTE, and BOTHE), A., i, 567.

1-Methyl-4-isopropyl-δ(3 or 3)-cyclohexen-3-ol, acetate of (MANNICH and HÁNCÚ), A., i, 276.

Methylisopropylcyclopentanes, synthesis of terpins, terpineols, and terpenes from (HAWORTH and PERKIN), T., 573; P., 64.

1-Methyl-3-isopropylcyclopentan-2-one and its oxime, semicarbazone, and 3-carboxylic acid (BOUVEAULT and LOCQUIN), A., i, 173.

1-Methyl-3-isopropylcyclopentan-2-one-1-carboxylic acid, ethyl ester (BOUVEAULT and LOCQUIN), A., i, 173.

1-Methyl-3- and -4-propyldienecyclohexanes and their nitrosochlorides and nitroplipperidines (WALLACH and RENT-SCHLER), A., i, 405.

δ-Methyl-α-isopropylmalic acid and its ethyl ester and silver salt (KÖTZ), A., i, 24.

Methylpropylcyclop propane (ZELINSKY and PERSCHEVSKY), A., i, 845.

3-Methyl-6-isopropyltritanolactone, 2-hydroxy- (V. LIEBIG), A., i, 541.

3-Methylisopulegol and its acetyl derivative (KUPPE and EBERT), A., i, 663.

3-Methylpyrazole-4-isopropylencarboxylic acid, 5-hydroxy-, lactone of. See 3:4-Dimethyl-1:2-pyrazo-6:7-pyrow.

3-Methylpyrazoline and its phenylcarbamide and picrate (MAIRE), A., i, 290.

3-Methylpyrazolone, 4-isonitroso- (BÜLOW and SCHAUER), A., i, 687.

3-Methylpyrazolone-4-isobutylencarboxylic acid and its lactone (WOLFF and SCHREINER), A., i, 291.
INDEX OF SUBJECTS.

1377

3-Methylpyrazoloneisopropylencarbonylic acid (WOLFF and SCHEINER), A., i, 292.

2-Methylpyridine. See α-Picoline.

4-Methylpyridine. See γ-Picoline.

2-Methylpyridine-3-carboxylic acid and its hydriodide and chloride (TURNAU), A., i, 912.

2-Methylpyridine-3:5-dicarboxylic acid, 6-hydroxy-, and its salts (SIMONSEN), T., 1030; P., 136.

ethyl-ammonium and ethyl-silver ester salts (SIMONSEN), T., 1028; P., 136.

4-Methylpyrimidine-5-acetic acid, 2:6-diamino-(JOHNSON and HEYL), A., i, 59.

Methylpyrimidines, 4- and 5-, 2-cyanoamino-6-hydroxy-, and their salts (POHL), A., i, 576.

6-Methyl-2-pyrone-3:5-dicarboxylic acid, ethyl ester, and its derivatives and reactions (SIMONSEN), T., 1022; P., 136.

2-Methyl-4-quinazolone, 7-amino-, and its nitro- and acetyl-derivatives (BOGER and KLABER), A., i, 467.

7-nitro- and its derivatives from 4-nitroacetylthranil (BOGER and KLABER), A., i, 466.

2-Methyl-4quinazolonyl-3-acetic acid and 3-α-benzoic acid, 7-nitro-, ethyl esters, amides, and nitriles (BOGER and KLABER), A., i, 468.

2-Methyl-4quinazolonyl-3-(2:5-dimethyl-3:4-dicarbethoxyxypyrrole), 7-nitro-(BOGER and KLABER), A., i, 468.

2-Methylquinoline (quinidine) and its additivet derivatives (HELLER and SOURIS), A., i, 913.

α-Methylisoserine, resolution of, into its optically active components, and its benzoyl derivatives (KAY), A., i, 772.

derivatives of (KAY), A., i, 773.

Methylisina-propionic acid (MAUTHNER), A., i, 729.

α-Methylisparteine, formation of, from isosparteine (VALEUR), A., i, 736.

new method of ring formation of, by the action of iodine (VALEUR), A., i, 1006.

isomerisation of (MOURE and VALEUR), A., i, 44.

MethyIspar tene, α- and β-, and their additive salts (MOURE and VALEUR), A., i, 44.

constitution of (MOURE and VALEUR), A., i, 206.

MethyIsulphony chloride, trichloro-, action of sodium ethoxide on (BROWN and COWIE), A., i, 3.

Methyl tannin. See Pentamethyl tannin.

Methyl-Δ3-α-tetrahydrocarbazoles, 4- and 9-, and 10-nitro- of the 4-compound (BORSCH, WITTE, and BOTHE), A., i, 366.

2-Methyl-Δ2-α-tetrahydrocycmene, 2-chloro- (RUPE and EMMERICH), A., i, 433.

1-Methyl-Δ2-tetrahydronicotinic acid. See Arecaidine.

methyl ester. See Arecoline.

1-Methyl-Δα-tetrahydropropyridine, 3-cyano-, hydrochloride of (WOHL and JOHNSON), A., i, 49.

1-Methyl-Δα-tetrahydropropyridine-3-aldehyde. See Arecaidinealdehyde.

2-Methyltetrahydroquinoline. See Tetrahydroquiniclaldehyde.

7-Methylthiocomaruin (CLAYTON), T., 527; P., 26.

α-Methylthiobenzoic acid (methylthiosaliclic acid), preparation of (FABERWerke VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 648, 797.

5-Methylthio-4-benzoyl-l-phenyl-3-methylpyrazole. See 4-Benzoyl-α-thioptipine.

Methylthionine, dinitro-, and its additive salts (GNEHM and WALDER), A., i, 64.

Methylthiosalicylic acid. See α-Methylthiobenzoic acid.

Methylthymines, 1- and 3- (JOHNSON, CLAPP, and MARTIN), A., i, 835.

Methyl-o-toluidine, preparation of (v. BRAUN), A., i, 626, 685.

Methyl-p-toluidine, preparation of (v. BRAUN), A., i, 626.

N-benzoyl derivative (v. BRAUN), A., i, 626.

Methyl-π-toluclidineacetonitrile (v. BRAUN), A., i, 626, 628.

α-Methyltricarballylic acid, formation of (HAWORTH and PERKIN), T., 591.

3-Methyltricarboxylic acid, 2-amino-, lactam of (v. LIEBIG), A., i, 646.

6-Methyltritanolactone, 2:4-dihydroxy-(v. LIEBIG), A., i, 541.

Methyltritanolactones, 2-hydroxy- (v. LIEBIG), A., i, 541.

3-Methyluracil, 5-bromo- (JOHNSON and CLAPP), A., ii, 836.

1-Methyluracil-3-acetic acid (WHEELER and LIDDLE), A., i, 639.

4-Methyluracil-5-acetic acid, synthesis of, and its esters and salts (JOHNSON and HEYL), A., i, 59.

β-Methylvaleric acid, α-amino-. See isoLeucine.

α-bromo- (EHRlich), A., i, 396.

Methylvanillylidenecetone and its hydrochloride (FRANCESCONI and CUSMANO), A., i, 802.
Methylvanillylideneinnamy1ideneacetone (Francesconi and Cusmano), A., i, 802.

1-Methyl-4-vinylbenzene, \( \beta \)-dichloro- (Zincke and Schubert), A., i, 337.

Methysticin, constitution of (Winzheiner), A., i, 804.

\( \psi \)-Methysticin (Winzheiner), A., i, 805.

Methysticol, and its phenylhydrazone, \( p \)-bromophenylhydrazone, and semicarbazone (Winzheiner), A., i, 805.

identity of, with piperonylenacetone (Winzheiner), A., i, 856.

Meyamite and tungstite (Walker), A., i, 507.

Mica, paragonite, a new variety of (Barbier), A., ii, 604.

Michler’s carbinol, replacement of hydroxyl in, by the alkylmethylen radicle (Fosse), A., i, 568.

Micro-balance, use of, for the determination of electrochemical equivalents and for the measurements of densities of solids (Brill and Evans), T., 1442; P., 185.

Microbes, action of the zinc ion on media for (Mendel), A., ii, 722.

Microchemical analysis. See under Analysis.

studies (Bolland), A., ii, 1080.

Microcline, composition of, from the pegmatites of Mesvres (Barbier), A., ii, 955.

and orthoclase, a chemical difference between (Barbier), A., ii, 704.

Micro-hydrometers, cylinder for (Gawalowski), A., ii, 479.

Micromeria Chamissonis (Yebra Buena), chemical examination of (Power and Salway), A., ii, 418.

Micromerol and its acetyl derivative and methyl ether and Micromeritol and its mono- and di-acetyl derivatives (Power and Salway), A., ii, 418.

Micro-organisms, influence of, on the utilisation of the potassium in leucite by plants (de Grazia and Camiola), A., ii, 415.

formation and decomposition of lactic acid by (Meissner), A., ii, 414.

phosphorus in the fat of (Allilair), A., ii, 123.

oxidising hydrogen (Nikleswski), A., ii, 314.

See also Bacteria, Fermentation, Microbes, and Yeast.

Microscopic analysis. See under Analysis.

Micro-voltameter. See under Electrochemistry.

Milk, curdling of, in the infant’s stomach (Keidl and Neumann), A., ii, 606.

human, behaviour of, to rennet and acids (Bienefeld), A., ii, 121; (Fuld and Wohlgemuth), A., ii, 311; (Engel), A., ii, 873.

human and cows’, available alkali in the ash of (Kastle), A., ii, 714.

cows’, the ferment which destroys lactose in (Vandevelde), A., ii, 713.

action of acids on the coagulation of, by vegetable rennets (Gerber), A., i, 745.

method for the determination of the accelerating action of sodium and potassium salts on the coagulation of, by ferments (Gerber), A., i, 71.

bacterial growth and chemical changes in, kept at low temperatures (Pennington), A., ii, 409.

freezing point of, a new method of detecting adulteration (Atkins), A., ii, 941.

the protein hydrolysis of (Vandevelde), A., ii, 211.

haemolytic factors in (Lane-Clayton), A., ii, 970.

peroxydase reaction of (Kastle and Porch), A., ii, 409.

heat and unheated, reaction for distinguishing between (Wilkinson and Peters), A., ii, 907.

heated or pasteurised, method of detecting (Lane-Clayton), A., ii, 970.

raw and pasteurised, peptonisation in (Colwell and Sherman), A., ii, 972.

effect of pasteurisation on the development of ammonia in (Whitman and Sherman), A., ii, 881.

Milk, estimation of fat in (Sidersky), A., ii, 238.

estimation of fat in skimmed (Lezé), A., ii, 75.

recovery of amyl alcohol from the acid liquors obtained in the Gerber process of estimating fat in (Richmond), A., i, 495.

detection of hydrogen peroxide in (Feder), A., ii, 318; (Wilkinson and Peters), A., ii, 907, 1069.

estimation of lactose in (Carrez), A., ii, 236; (Guérin), A., ii, 329; (Shimizut), A., ii, 991.

estimation of lecithin in (Nerking and Haensel), A., ii, 999.

estimation of potassium dichromate in (Gouère), A., ii, 325.
Milk, rapid estimation of water in (THÖRNER), A., ii, 222.
Milk proteins and enzymes (Olsen), A., i, 1031.
Milk-serum (LANDOFF), A., ii, 714.
Milk sugar. See Lactose.
Millon's base, thermochemical data relating to the chlorinated compounds from (GAUDECHON), A., ii, 85, 383.
Mineral acids. See under Acids. chemistry (LOCZKA), A., ii, 394.
phosphates, behaviour of, in soil (MONTANARI), A., ii, 128.
water. See under Water.
substances, triboluminescence of (KARL), A., ii, 549.
sulphides. See under Sulphur.
Minerals, coloration of (SIMON), A., ii, 954.
influence of fine grinding on the water and ferrous iron content of (HILLEBRAND), A., ii, 778.
and industrial products, decomposition of certain, by means of sodium peroxide and metallic sulphides (WALTON and SCHOLZ), A., ii, 732.
containing uranium, helium in (BORDAS), A., ii, 505.
helium and radioactivity in (STRUTT), A., ii, 649.
Australian, radioactivity in, and occurrence of radium in (MAWSON and LUBY), A., ii, 917.
polymorphous (WEBER), A., ii, 302.
radioactive. See under Photochemistry.
saline, helium in, and its probable connexion with potassium (STRUTT), A., ii, 923.
detection of small quantities of helium in (BORDAS), A., ii, 430.
detection of phosphoric acid in (LIDOFF), A., ii, 894.
Mirrors, violet coloration of the glass of, produced by the action of light (MASCHHAUTT), A., ii, 1003.
Mistletoe. See VISCUUM ALBUM.
Mists, formation of, in presence of radium emanation (CURIE), A., ii, 7, 797.
Mitscherlich's apparatus, receiver for (HABERMANN), A., ii, 17.
Mixtures, binary, heat-contents of (TAMMANN), A., ii, 660.
Molasses, formation of (LEBEDEFF), A., i, 608.
Molecular aggregations produced in gases by sudden cooling (OWEN and HUGHES), A., ii, 505.
attraction, examination of seven esters (MILLS), A., ii, 84.
complexity of amides in various solvents (MELDRUM and TURNER), T., 876; P., 98.
compounds, reciprocal displacement of the constituents of, and their relative stability (MENSCHUTKIN), A., ii, 170.
conductivities of α-oximino-fatty acids (INGLS and KNIGHT), T., 1595; P., 191.
and ionisation of electrolytes in aqueous solutions as conditioned by temperature, dilution, and hydrolysis (JONES and JACOBSON), A., ii, 1011.
magnetic field and specific heat of ferromagnetic substances (WEISS and BECK), A., ii, 659.
masses, method of measuring large (SUTHERLAND), A., i, 930.
refractions. See under Photochemistry.
weights. See Weights, molecular.
Molecules, polymerisation and dissociation of, in the liquid state (LONGINESCU), A., ii, 931.
the size of, and charge of the electron (PERRIN), A., ii, 927.
Molybdates. See under Molybdenum.
Molybdenum, quantitative spectra of (LEONARD), A., ii, 645.
new element allied to (OGAWA), A., ii, 953.
compounds with uranium (LANCIEN), A., ii, 699.
with uranium. See also Uranyl molybdate.

tervalent, thiocyanates of (ROSENHEIM and GARFUNKEL), A., i, 614.

Molybdic acid and vanadic acid, estimation of, in presence of one another (EDGAR), A., ii, 540.
Molybdates, anhydrous (GROSCHUFF), A., ii, 501.
of the rare earths, complex (BARBIERI), A., ii, 595.
INDEX OF SUBJECTS.

Molybdenum silicate (DefaCoq), A., ii, 595.

Molybdenum, hexathiocyno-salts of (Maas and Sand), A., i, 397, 513, 961; (Rosenheim and Garfunkel), A., i, 614.

Molybdenum, colour test for (Betzel), A., ii, 230.

Molybdic acid. See under Molybdenum.

Monazite sand, chemical constitution of a North American (Tschernik), A., ii, 302.

Montmorillonite, ratio of alumina and silica in (Stremme), A., ii, 1041.

Mordant dyes, theory of (Werner and Thomann), A., i, 440; (Liebermann), A., i, 441; (Tschugaeff; Werner), A., i, 669.

Morinda citrifolia, constituents of the root-bark of (Oesterle and Tisza), A., ii, 527.

Morindanigrin and Morindadiol and its diacetyl derivative (Oesterle and Tisza), A., ii, 527.

Morindin and its acetyl derivative (Perkin), P., 149.

and its acetate and benzoate (Oesterle and Tisza), 'A., i, 36.

Morindone trimethyl ether (Oesterle and Tisza), A., i, 37.

Morphide, α-chloro-, hydrolytic products of (Opfè), A., i, 362.

Morphine (Knorr and Hörein), A., i, 41, 42, 361; (Knorr and Raabe), A., i, 908.

constitution of (Bucherer), A., i, 43.

action of free alkalis on (Grubler), A., i, 204.

constipating action of (Magnus), A., ii, 412.

alkyl bromides, preparation of (Riedel), A., i, 452.

γ-isomorphine and its acetyl derivative and additive salts (Opfè), A., i, 362.

apoMorphine and ψ-apocodeine, relation between (Knorr and Raabe), A., i, 908.

Morphines, four isomeric, relationship of, to the codeines (Knorr and Hörein), A., i, 42.

Morphine diabetes. See Diabetes.

Morpholquinone from phenanthrene (Schmidt and Söll), A., i, 995.

Mortar, microscopic study of (Gallo), A., ii, 843, 844.

See also Cement.

Moser rays. See under Photochemistry.

Moulds, oxidation by means of (Herzog and Meier), A., ii, 1063.

Moulds, conversion of cinnamic acid into styrene by means of (Herzog and Ripke), A., ii, 1064.

See also Yeast.

Mouse tumours, glycogen in (Haaland), A., ii, 612.

Muconic acid, dichloro-, constitution of (Radulescu), A., i, 604.

Mud from the baths of Fitero Viejo. See Waters of Fitero Viejo.

Mulberry tree, the most favourable ratio of lime to magnesia for the (Nakamura), A., ii, 126.

Mummies, fatty acids from (Schmidt), A., ii, 878.

Muscarine, synthetical, fate of, in the organism (Fühner), A., ii, 1061.

quantitative estimation of, by physiological methods (Fühner), A., ii, 877.

Muscle, physical chemistry of excitation of (Höber), A., ii, 121.

contraction of, and receptive substances (Langley), A., ii, 120, 769.

temperature-coefficient of rate of conduction and latent period in (Woolley), A., ii, 711.

formation of lactic acid and carbon dioxide in (Latham), A., ii, 609.

of birds, action of barium chloride on (Edmund and Roth), A., ii, 966.

of frog, creatine and creatinine in (Brown and Cathcart), A., ii, 516.

mammalian cardiac, consumption of dextrose by (Locke and Rosenheim), A., ii, 120.

non-striated mammalian (Saiki), A., ii, 712.

striated, contraction of (Macdonald), A., ii, 712.

of reptiles. See Reptiles.

Muscle coagulation, decomposition of blood platelets, and blood coagulation (Bürker), A., ii, 510.

Muscle extracts (Krimberg), A., i, 41, 842; ii, 609.

Muscle plasma (Mellanby), A., ii, 713.

Muscular activity and protein metabolism (Shaffer), A., ii, 961.

the utilisation of sugar during (Müller), A., ii, 713.

Muscular contraction and receptive substances (Langley), A., ii, 874.

Mustard oil, estimation of, volumetrically (Kuntze), A., ii, 440.

See also Allylthiocarbimide and Phenylthiocarbimide.

Musts, detection of nitrates in (Marsiglia), A., ii, 894.

estimation of lactic acid in (Leger), A., ii, 438.
N.

α-Naphthaflavonol, 3'- and 4'-hydroxy- (v. Kostanek, Engelsohn, and Wenzelmann), A., i, 359.

1-Naphthaldehyde, 3-bromo-4-hydroxy-, synthesis of, and its products with amines, and 4-hydroxy-, and its azine and additive compound with hydrazine sulphate (Gattermann), A., i, 29.

2-chloro-4-hydroxy- and 2-hydroxy- (Friedländer), A., i, 373.

hydroxy-, trimethylene ether of, and its derivatives (Gattermann), A., i, 35.

2-Naphthaldehyde, 1-hydroxy-, and its hydrazone (Friedländer), A., i, 373.

4-Naphthaldehyde, 1:5-dihydroxy-, and its compound with aniline, synthesis of (Gattermann), A., i, 30.

Naphthalene and its derivative, absorption spectra of (Baly and Tuck), T., 1902; P., 223.

and β-naphthol, crystals of, and of their mixtures (Miers and Isaac), T., 927; P., 125.

freezing-point surfaces of the system chlorobenzene, phenol, and (Himode), A., ii, 928.

freezing-point curves of mixtures of phenol and (Yamamoto), A., ii, 928.

oxidation of (Law and Perrin), T., 1937; P., 195.

bran from (v. Kostanek and Lamp), A., i, 671.

homologues of (Bargellini and Melacini), A., i, 775.

new method of preparing (Darzens and Rost), A., i, 411.

absorption spectra of the hydrocarbons isolated from the products of the action of aluminium chloride on (Homer and Purvis), T., 1319; P., 147.

Naphthalene sthynate, α-bromo- (Gibson), T., 2099; P., 241.

estimation of, in coal gas and in spent oxide of iron (Gair), A., ii, 135.

Naphthalene, amino-. See Naphthylamines.

diamino-. See Naphthylendiamine.

Naphthaleneazo-ββ-dinaphtylamines, α- and β- (Fischer and Straus), A., i, 222.

Naphthaleneazoguaiacols, α- and β-, and the acetyl derivative of the α-compound (Colombano and Leonard), A., i, 68.

4-Naphthaleneazo-3-methyl-5-pyrazolones, α- and β-, and their 1-benzoyl derivatives (Bulow and Schaub), A., i, 705.

β-Naphthaleneazophenol and its acetyl derivative (Grandmougin and Freimann), A., i, 1024.

β-Naphthalene-4-azoresorcinol (Orton and Everett), T., 1019.

Naphthaleneazo-. See also Naphtholazo-, and Naphthylazo-.

Naphthalene-carboxylic acid. See Naphthoic acid.

Naphthalene-3:6-disulphonic acid, 1:8-dihydroxy-. See Chromotropic acid.

Naphthalene-indole-indigotin (Friedländer), A., i, 372.

α-Naphthalenesulphonic acid, preparation of (Knoevenagel and Kenner), A., i, 971.

Naphthalene-6-sulphonic acid, 2:3-dihydroxy-, azo-compounds from the α-aminophenols and (Chemische Fabrik Griesheim-Elektron), A., i, 430.

Naphthalene-8-sulphonic acid, hydroxy-. See 1-Naphthol-8-sulphonic acid.

Naphthalensulphonic acids, cerium salts (Erdein and Nieszytka), A., i, 621.

Naphthalene-β-sulphonylaminothienyldiazonium salts (Morgan and Micklethwait), T., 618.

Naphthalene-β-sulphonylbenzidine and -p-nitroaminodiphenyl (Morgan and Micklethwait), T., 617.

as- Naphthalene-β-sulphonyl ethyl benzidine and -diphenyldiazonium salts and their azo-β-naphthols (Morgan and Micklethwait), T., 620.

Naphthalene-β-sulphonylnitroethylaminodiphenyl (Morgan and Micklethwait), T., 620.

β-Naphthalenesulphonyltrytophans (Ellinger and Flamand), A., i, 378.

α-Naphthalides, anilides, and p-toluclidies of normal fatty acids, melting points of (Robertson), T., 1033; P., 120.
Naphthanthraquione and its sulphonic acid (Heller and Schülke), A., i, 994.

αβ-Naphthaphenazine-α- and -αβ-naphthazines and their salts (Fischer and Schindler), A., i, 221.

Naphtha-phenazion and its chloride and -phenazine and its hydrochloride, 9-hydroxy- (Kehrmann and Brunel), A., i, 580.

Naphthaprasindone, amino-, and its acetyl derivative and salts (Kehrmann and Schwarzenbach), A., i, 297.

Naphthaquinoline group, synthesis in the (Simon and Mauguin), A., i, 296.

α-Naphthaquinone antimony pentachloride (Meyer), A., i, 731.

β-Naphthaquinone, 7-hydroxy-, azonium compounds and azines from (Kehrmann and Brunel), A., i, 579.

Naphthaquinoxaline, formation of, and its picrate (Fischer and Romer), A., i, 695.

Naphtharesorcinol as a reagent for certain aldehyde- and ketone-azides (Mandel and Neuberg), A., ii, 998.

Naphthazine, dihydroxy-, and its diacetyl derivative (Fischer and Schindler), A., i, 221.

Naphthazines, oxidation of, by chromic acid (Fischer and Schindler), A., i, 221.

αβ-Naphthazines (Fischer and Straus), A., i, 222.

β-Naphthindigotin, bromo-, preparation of (Gesellschaft für Chemische Industrie in Basel), A., i, 695.

Naphthro-blue, preparation and reactions of (Noeling and Philipp), A., i, 295.

Naphthoic acid hydrazide, β-hydroxy-, and its benzylidene derivative (Franzen and Eichler), A., i, 831.

α-Naphthoic acid, 2-hydroxy-, and its ethyl ester (Lassar-Cohn and Löwenstein), A., i, 985.

β-Naphthoic acid, bromoimino- and chloroimino-, esters (Hilpfer), A., i, 830.

Naphthol derivatives, formation of, from papaverine and the binuclear quinones of the naphthalene series (Decker), A., i, 806.

β-Naphthol and naphthalene, crystals of, and of their mixtures (Miers and Isaac), T., 927; P., 125.

action of methylchloroacetamide on (Einhorn), A., i, 612.

molecular compound of, with 2:3:5-trinitro-4-acetylaminophenol (Meldola and Hay), P., 210.

2-Naphthol, 1-amino-, N-benzoyl derivative of (Auwers and Eisenlohr), A., i, 229.

N- and O-benzoyl and -anisoyl derivatives of (Scheiber and Brandt), A., i, 726.

7-amino- and 7-chloro- (Franzen and Diebel), A., i, 833.

Naphthols, reaction of, with diazonium salts (Orton and Everatt), T., 1010; P., 118.

new differential reactions of the (Volcy-Boucher), A., ii, 990.

azo-derivatives of (Orton and Everatt), T., 1020.

β-Naphtholazobenzene-4-arsenic acid and its sodium salts (Barlowcliff, Pyman, and Remfry), T., 1897.

α-Naphthol 3-sulphonic acid, 5-amino-preparation of (Cassella & Co.), A., i, 160.

1-Naphthol-8-sulphonic acid, cerium salts (Erdmann and Nieszytka), A., i, 622; (Erdmann and Wikin), A., ii, 695.

Naphthyl arsenite (Lang, Mackey, and Gortner), T., 1370; P., 151.

α-Naphthyl trimethylene ether (Gattermann), A., i, 35.

β-Naphthyl trimethylene ether and its dialdehyde (Gattermann), A., i, 35.

α-Naphthyl acetone and acetalddehyde, and their semicarbazones (Tiffeneau and Daudel), A., i, 973.

N-α-Naphthylaldoximes (Scheiber and Beckmann; Scheiber and Brandt), A., i, 725.

α-Naphthylamine picrates (Suida), A., i, 523.

β-Naphthylamine, condensation of, with aldehydes and ketones (Rothenfusser), A., i, 52.

1-bromo- and 1-chloro-, condensation of, with methylene chloride (Senier and Austin), T., 63.

1-β-Naphthylaminobenzene, 4-chloro-2:6-dinitro-, preparation of (Ullmann), A., i, 627.

Naphthylarsenic acid, amino- and hydroxy- (O. and R. Adler), A., i, 492.
Naphthal-4-arsinic acid, 1-amino- (FENZ and KAHN), A., i, 592.
Naphthylazoacetacetic acids, α- and β-, ethyl esters, benzoylhydrzones of (BULOW and SCHAU), A., i, 705.
Naphthylazo. See also Naphthaleneazo, and Naphtholazo.
α-Naphthylbenzylamine and its hydrochloride (BUSCH and LEEFHELM), A., i, 152.
β-Naphthyl-β-benzylthiocarbamide, cyano- (FROMM and WELLER), A., i, 703.
Naphthylearboximide, reactions of (VALLEE), A., i, 976.
α-Naphthylchlorosilicane (MELZER), A., i, 976.
Naphthyldiacetonitriles, α- and β- (v. MEYER and SCHUMACHER), A., i, 906.
1:3-Naphthylenediamine, formation of, from β-imino-α-cyano-γ-phenylpropionate (BEST and THORPE), F., 285.
2:7-Naphthylenedihydrazine and its dibenzylidine derivative (FRANZEN and DEIBEL), A., i, 833.
α-Naphthylethylene (TIFFE NEAU and DAUDEL), A., i, 973.
Naphthyl group, migration of, in iodohydroins of the naphthalene series (TIFFE NEAU and DAUDEL), A., i, 972.
β-Naphthylhydrazine, condensation of, with aldehydes and ketones (ROTHENFUSser), A., i, 52.
β-Naphthylhydrazine, 7-amino-, and 7-hydroxy- and their benzylidine derivatives (FRANZEN and DEIBEL), A., i, 832.
N-α-Naphthylhydroxylamine, aldoxide ethers from (SCHIEBER and BECKMANN; SCHEIDER and BRANDT), A., i, 725.
β-Naphthylmethylnamineacetonitrile (v. BRAUN), A., i, 628.
β-1- and 2-Naphthyl-β-methylglycidic acids and their ethyl esters (DARZENS), A., i, 91.
Naphthyl methyl ketones, α- and αβ-, semicarbazones of (DARZENS), A., i, 91.
β-Naphthyl-3-methylpyrazolone, 7'-hydroxy- (FRANZEN and DEIBEL), A., i, 832.
a-1- and 2-Naphthylpropaldehydes and their semicarbazones (DARZENS), A., i, 91.
a-1-Naphthylpropionic acid (TIEFFENEAU and DAUDEL), A., i, 973.
Naphthylpropylenes, α- and β- (TIEFFENEAU and DAUDEL), A., i, 972.
β-Naphthyl propyl ketone, crystallography of (BARGELLINI and MELACINII), A., i, 775.
β-Naphthylesemicarbazide, 7-hydroxy- (FRANZEN and DEIBEL), A., i, 832.
α-Naphthylsilico-acid and the ester of the ortho-acid (MELZER), A., i, 967.
α-Naphthylthiolic-acid, preparation of (KALLE & CO.), A., i, 605.
β-Naphthyl-thiuret hydrochloride and -dithiobiuret (FROMM and WELLER), A., i, 703.
β-α-Naphthylxylolside, synthesis of (RYAN and EBRILL), A., i, 716.
Narcosis, physical chemistry of (HÖBER), A., ii, 121.
Narcotinesulphonic acid (KNOLL & CO.), A., i, 285.
Natrochalcite, a new mineral from Chile (PALACHE and WARREN), A., ii, 1047.
Natural waters. See under Water.
Neodymium, anomalous magnetic rotatory dispersion of (WOOD), A., ii, 244.
Neodymium salts, borax bead test for (MILBAUER), A., ii, 70.
Neodymium fluoride (POPÓVlC), A., ii, 283.
Neo-erbium (HOFMANN and BURGER), A., ii, 189.
Neo-erbium oxide, spectrum of, and Kirchoff's law (HOFMANN and BUGGE), A., ii, 1002.
Neon, helium, xenon, and krypton, percentage of, in the atmosphere (RAMSAY), A., ii, 688.
Neosine, constitution of (ACKERMANN and KUTSCHE), A., i, 875.
Neottine, a triminophosphatide (FRANKEL; BOLAFFIO), A., i, 377.
Neo-ytterbium (URBAIN), A., ii, 283, 849.
Nepheline, composition of (MOROZEWICZ), A., ii, 201.
Nepheline-syenite from Los Islands, sodium fluoride in (LACROIX), A., ii, 200.
Nernst-glower, certain phenomena exhibited by small particles of metals on a (MENDENHALL and INGERSOLL), A., ii, 151.
Nerve, temperature-coefficient of rate of conduction in (LUcas), A., ii, 711. action of certain narcotics on (BETHE), A., ii, 1059.
great splanchnic, influence of stimulation of, the when the liver is deprived of its blood supply (MACLEOD and RUTH), A., ii, 770. glycogenolytice fibres in the (MACLEOD), A., ii, 770.
Nerve conduction, temperature-coefficient of the velocity of (Snyder), A., ii, 608.
Nerve degeneration, the chemical test for diseases due to (Bauer), A., ii, 717.
endings, action of curare and eserine on (Edmund and Roth), A., ii, 966.
fibres, action of aconitine on (Waller), A., ii, 55.
medullated, Weigert's method of staining (Smith, Mayer, and Thorpe), A.; ii, 966.

Nerves, chemical and physical properties of (Alcock and Lynch), A., ii, 51.
autonomic, action of nitrites and atropine on (Fröhlich and Loewi), A., ii, 711.
peripheral, chemical composition of (Falk), A., ii, 965.
of the frog. See Frog.

Nervous system, sulphur compounds of the (Koch), A., ii, 52.

Neurokeratin (Argiris), A., i, 70.

Neuronal, constitution of (Mannich and Zernik), A., i, 399.

Neutral salt action, experimental and thermodynamic researches on (V. Szyyszewski), A., ii, 761.

Neutral regulation in the animal organism, theory of (Henderson), A., ii, 467.

New Victoria Blue. See Victoria Blue R.

Niaouli oil (Schimmel & Co.), A., i, 666.

Nickel, change of density and specific heat of, after treatment, and the dependence of the specific heat on the temperature (Schlett), A., ii, 563.
passivity of (Fredenhagen), A., ii, 679.
cobalt, and iron, experiments on the passivity of (Byers), A., ii, 1026.
equilibrium in the system, bismuth and (Portevin), A., ii, 45.
and hydrogen, relationships between (Mayer and Altmayer), A., ii, 950.
and copper solutions, colorimetric comparison of (Milbauer), A., ii, 71.

Nickel alloys with aluminium (Gwyer), A., ii, 285.
with bismuth, cadmium, chromium, lead, magnesium, thallium, tin, and zinc (Voss), A., ii, 194.
with copper and zinc, constitution of (Tafel), A., ii, 846.
with thorium (Chauvenet), A., ii, 858.
with zinc (Tafel), A., ii, 105, 846.

Nickel compounds with phosphorus (Konstantinoff), A., ii, 855.

Nickel salts, abnormal behaviour of, on hydrolysis (Denham), A., ii, 380.

Nickel arsenides (Vigouroux), A., ii, 855.
chloride, free energy of (Thompson and Sage), A., ii, 468.
ammonium chromates (Gröger), A., ii, 691.
molybdate and cobalt molybdate (Pozzi-Escot), A., ii, 1042.

Nickelous oxide, dissociation pressure of (Poote and Smith), A., ii, 847.

Nickel oxide, reduction and oxidation of, under ordinary and high pressures (Ipatieff), A., ii, 594.

Peroxide electrodes. See Electrodes under Electrochemistry.
sulphide, compounds of, with bismuth and potassium sulphide (I. and L. Bellucci), A., ii, 196.
sulphides, freezing-point curve of the (Bornemann), A., ii, 292.

Nickel pyridine thioycyanate, action of iodine on (Pfeiffer and Tilgner), A., i, 614.

Nickel, detection of (Pozzi-Escot), A., ii, 229; (Grossmann and Schück), A., ii, 230, 899.
detection of, as double nickel ammonium molybdate (Pozzi-Escot), A., ii, 133.
and cobalt, simultaneous qualitative test for (Grossmann and Heilborn), A., ii, 635.
and cobalt, detection and estimation of (Pozzi-Escot), A., ii, 899.
detection of, in ores and nickel-steel (Grossmann), A., ii, 434.
detection and estimation of, in presence of cobalt, iron, and manganese (Pozzi-Escot), A., ii, 229.
estimation of (Pozzi-Escot), A., ii, 635.
estimation of, volumetrically (Cantoni and Rosenstein), A., ii, 230.

Brunck's dimethylglyoxime process for the estimation of (Grossmann and Schück), A., ii, 71.
rapid estimation of, in presence of all elements of groups 4, 5, and 6 (Pozzi-Escot), A., ii, 635.
estimation of, in presence of a large excess of cobalt (Pozzi-Escot), A., ii, 324.
and cobalt, colorimetric estimation of, in presence of each other (Chalinor), A., ii, 988.
estimation of, in steel (Blair), A., ii, 900.
and chromium, estimation of, in steel (Campbell and Arthur), A., ii, 779.
and carbylamines, character and re-
actions of (Guillemand), A., i, 718.
reduction of, in neutral solutions
(Brunner and Rapin), A., i, 853.
See also α-Amino-nitriles.

Nitrogen, atomic weight of (Leduc), A., ii, 271.
application of the method of limiting
densities to the atomic weight of
(Guye), A., ii, 17.

INDEX OF SUBJECTS.

Nickel and cobalt, estimation and separa-
tion of (Pozzi-Escor), A., ii, 229, 539, 540.
electrolytic estimation of, in nitrate
solutions and its separation from
copper (Thiel), A., ii, 539.
and cobalt, separation of iron from
(Laby), A., ii, 988.
electrolytic separation of zinc and
(Foerster and Treadwell; Fischer), A., ii, 324.
Nickel matte, constitution of (Bornemann), A., ii, 292.
Nickelous oxide. See under Nickel.

Nickel steel, gases occluded in a special
(Belloc), A., ii, 852.
detection of nickel in (Grossmann),
A., ii, 434.

Nitratine, 6-chloro- (Mills and
Widdows), T., 1379; P., 174.

Nicotinic acid hydriodide (Turnau), A.,
i, 912.

Nicotinic acid, hydroxy-, ethyl ester,
and hydrazide of (Mills and
Widdows), T., 1381; P., 174.

Nicotinic acid hydriodide (Turnau),
A., i, 912.

Nigella, alkaloids of the species of
(Keller), A., i, 283.

Nitobium. See Columbium.

Nipponium and its oxides, chloride, and
hydroxide, from thorianite (Ogawa),
A., ii, 952, 953.

Nitrates. See under Nitrogen.

Nitration, studies in (Tingle and Rolk-
er), A., i, 408, 974; (Tingle and
Blanck), A., i, 778, 893.
influence of sulphuric acid in (Kull-
gren), A., i, 768.

Nitric acid and oxide. See under
Nitrogen.

Nitric oxide electrode. See under
Electrochemistry.

Nitrides, preparation of, from metallic
oxides or salts with the aid of
atmospheric nitrogen (Borchers
and Beck), A., ii, 836.
See also under the various Metals and
Metalloids and Metallic nitrides.

Nitrification (Coleman), A., ii, 315.
influence of organic matter on, in
impure cultures (Karpiński and
Niklewski), A., ii, 123.
in acid soils (Hall, Miller, and
Gimingham), A., ii, 524.
in black soils (Sasanoff), A., ii, 614.
See also Bacteria, nitrifying.

Nitrite, \( \text{C}_6\text{H}_5\text{O}_2\text{N}_2 \), from the reduction
of the acid, \( \text{C}_6\text{H}_5\text{O}_2\text{N}_3 \) (Windaus),
A., i, 728.

XCIV. ii.
Nitrogen and hydrogen, chemical action of radium emanation on (Cameron and Ramsay), T., 984; P., 132.
thermochemistry of (Thomlinson), A., ii, 1016.
asymmetric (E. and O. Wedekind), A., i, 258; (E. and O. Wedekind and Paschke), A., i, 334.
effect of ether anaesthesia on the excretion of (Hawk), A., ii, 410.
inefluence of potassium cyanide on the excretion of, in dogs (Welker), A., ii, 411.
ammoniacal, movement of, in nature (Ehrenberg), A., ii, 60.
in soil. See under Manurial experiments and Soil.
organic compounds of phosphorus, sulphur, and, in vegetables (Stutzman), A., ii, 124.
combination of, with calcium carbide (Pollacci), A., ii, 836.
Nitrogen oxides, formation of, in the ozone generator (Manchot), A., ii, 272.
analysis of, by means of their ultra-red absorption spectra (Warburg and Leithäuser), A., ii, 175.
dioxide (nitric oxide), formation of, in high tension arcs (Haber and Koenig), A., ii, 34, 940.
gaseous, refractive index of (Cuthbertson and Metcalfe), A., ii, 545.
solubility of, in aqueous solutions of ferrous sulphate, nickel sulphate, cobalt sulphate, and manganese chloride (Usnier), A., ii, 487.
and oxygen, interaction of (Mandl and Russ), A., ii, 272; (Holwech), A., ii, 941.
peroxide or tetroxide, preparation of (Winans), A., ii, 487.
ozone, and hydrogen peroxide, formation of, in reactions in air which develop high temperatures (Keiser and McMaster), A., ii, 223.
ozone, and hydrogen peroxide, detection of, in gaseous mixtures (Keiser and McMaster), A., ii, 222.
Nitric acid and nitrous acid, preparation of (Foerster and Koch), A., ii, 941.
production of, during electric discharge in air (Meyer), A., ii, 487.
interaction of, with copper in presence of metallic nitrates (Kennie, Higgins, and Cooke), T., 1162; P., 141.

Nitrogen:
Nitric acid, action of, on metals (Stansbie), A., ii, 497.
compound of, with mercuric cyanide (Hofmann and Wagner), A., i, 514.
detection of, in wine and must (Marsiglia), A., ii, 894.
estimation of (Jannasch), A., ii, 430.
estimation of, electrolytically (Shinn), A., ii, 893.
limitations of the copper-zinc couple method in estimating, in waters (Purvis and Courtault), A., ii, 776.
employment of nitron for estimating, in plants and soils (Litzendorf), A., ii, 130.
nitrites, and ammonia, estimation of, in sea-water (Ringer and Klingan), A., ii, 320.
Nitrates in vegetable foods, cured meats, and elsewhere (Richardson), A., ii, 208.
behaviour of, in paddy soils (Dai-Kurara and Iwaseki), A., ii, 127.
manurial experiments with different kinds of (Sebelien), A., ii, 61.
Nitrous acid and nitric acid, preparation of (Foerster and Koch), A., ii, 941, 1031.
limitations of the copper-zinc couple method in estimating, in waters (Purvis and Courtault), A., ii, 776.
nitrites, and ammonia, estimation of, in sea-water (Ringer and Klingan), A., ii, 320.
Nitrates, preparation of pure, from nitrous fumes (Badische Anilin- & Soda-Fabrik), A., ii, 175.
Hyponitrous acid, decomposition of (Divers), P., 16.
Nitrogen sulphide and its compounds (Wöblings), A., ii, 272.
Nitrogen, estimation of (Richmond), A., ii, 530.
estimation of, by Dumas' method (Leemann), A., ii, 629.
estimation of total, including nitrates, in presence of chlorides (Richardson), A., ii, 428.
modification of Kjeldahl's process for estimating, in foods (Corradi), A., ii, 130.
colorimetric estimation of, in soils (Chouchak and Pouget), A., ii, 223.
Nitrogen, estimation of, in urine (Hawk), A., ii, 64.

Nitrogen compounds, effect of constitution on the optical activity of (Everatt), T., 1225; P., 148.

optically active, effect of constitution on the rotatory power of (Everatt and Jones), T., 1789; P., 212.

syn- and anti-stereoisomerism of (Stieglitz), A., i, 726.

catalytic action of finely-divided metals on (Padoa and Scaglirini), A., i, 828.

action of finely-divided metals on (Padoa and Chiaves), A., i, 104.

cyclic, mechanism of the synthesis of (Simon and Mauguin), A., i, 296; (Simon), A., i, 687, 738.

inorganic, preparation of; lecture experiments (Raschig), A., ii, 30.

Nitrogenous metabolism. See under Metabolism.

Nitrogenous substances, use of silver in the combustion of (Epstein and Doht), A., ii, 132.

Nitro-group, reduction of. See under Nitro-compounds.

Nitrohydride derivatives, aromatic, preparation of (Wolffenstein and Böters), A., i, 629.

Nitroso compounds, relation between the absorption spectra and chemical constitution of (Balz and Desch), T., 1747; P., 173.

and nitro-compounds, aromatic, question of the miscibility and formal analogy in (Jaeger), A., i, 147.

Nitrosyl fluoride, compounds of, with antimony and arsenic pentfluorides (Ruff, Stäuber, and Graf), A., ii, 584.

Nomenclature of glyoxilic peroxides (Wieland and Semper), A., i, 108.

of proteins (Report of a Joint Committee of the American Physiological Society and the American Society of Biological Chemists), A., i, 301.

of thorium compounds (Hahn), A., ii, 454.

nonadecamethylene dicarboxylic acid (Eberhardt's acid) and its ethyl ester, silver salt, and diamide (Schaal), A., i, 4.

Nonaldehyde. See Paranonaldehyde.

Nonane, dihydroxy-. See \( \beta \beta \)-Dimethyl-\( \gamma \)-ethylpentane-\( \gamma \)-diol.

Nonanediacarboxylic acids. See \( \delta \)-Methyl-\( \alpha \)-isopropyl-pimelic acid and isopropylisobutylsuccinic acids.

Non-electrolytes, calculation of the diffusion constants of (V. Wogau), A., ii, 817.

osmotic pressure of concentrated solutions of (Sackur), A., ii, 931.

Nonenyl alcohols. See \( \beta \beta \)-Dimethyl-\( \gamma \)-ethyl-\( \Delta \)-\( \gamma \)-pentenol and \( \delta \delta \)-Dimethyl-\( \Delta \)-hepten-\( \delta \)-ol.

Non-homogeneous mixtures, thermodynamics of (Bose and Clark), A., ii, 84.

Noninene. See \( \eta \)-Methyl-\( \Delta \beta \)-octadiene.

Non-miscibility and the mass law (Bancroft), A., ii, 161.

Nononaphthene, occurrence of, in coal tar, and its derivatives (Ahrens and v. Mozidzenski), A., i, 618.

Nonylene glycol. See \( \beta \beta \)-Dimethyl-\( \gamma \)-ethylpentane-\( \gamma \)-diol.

Nopinene. See \( \beta \)-Pinene.

Nopinol acetate and its isomeride (Wallach), A., i, 988.

Nopinone, synthesis of fenchene, \( \beta \)-pinene, camphene, and camphor from (Wallach), A., i, 997.

Norborneol chloride (Semmler and Bartelt), A., i, 195.

\( \eta \)-Norbornylamine and its oxalate, picrate, and hydrochloride (Semmler and Bartelt), A., i, 195.

Norcamphene. See Santene.

\( \eta \)-Norcampholic acid and its nitrile (Semmler and Bartelt), A., i, 195.

\( \eta \)-Norcamphor, benzyldene derivative and oxime of (Semmler and Bartelt), A., i, 195.

\( \eta \)-Norcamphoric acid and its methyl ester and anhydride (Semmler and Bartelt), A., i, 195.

Nuclei, condensation, produced by cooling gases to low temperatures (Owen and Hughes), A., ii, 565.

Nucleic acid, the carbohydrate group in (Steudel), A., i, 487, 710.

of the pancreas (v. Fehr and Jerusalem), A., ii, 119.

See also Guanylic acid.

Nucleic acid cleavage products of (Levene; Steudel), A., i, 931.

pyrimidine derivatives in (Osborne and Heyl; Levene and Mandel), A., i, 376.

compound of, with uric acid (Seo), A., i, 70.

Nucleic acids (Levene and Mandel), A., i, 586.

in animals (Schmiederberg), A., i, 70.

of animal origin, the origin of cytosine obtained by the hydrolysis of (Levene and Mandel), A., i, 376.

of pancreas, spleen, and thymus; identity of (Jones), A., i, 744.
Nucleic acids, soluble silver compounds of, and their derivatives (Farbenfabriken vorm. F. Bayer & Co.), A., i, 376. See also Thymonucleic acid.

Nuclein metabolism. See under Metabolism.

Nucleo-protein, reaction distinguishing phosphoprotein from (Plimmer and Scott), T., 1699 ; P., 200. of the liver (Levene and Mandel), A., i, 587. of the placenta (Savare), A., i, 69.

Nucleo-proteins, constitution of (Hugounenq and Morel), A., i, 744.

Nutmeg, constituents of the expressed oil of (Power and Salway), T., 1653 ; P., 197.

Oats, the protein changes taking place in, when kept in the dark (Butkewitsch), A., ii, 884. assimilation and elimination of nutrients by, at different periods of vegetation (Seidlcr and Stutzer), A., ii, 1065.

Obituary notices:—

John Clark, T., 2275.
August Dupré, T., 2269.
Sir David Gamble, T., 2279.
Frederick James Montague Page, T., 2277.
Sir William Henry Perkin, T., 2214.
Robert Warington, T., 2258.

Oblotine, relation of, to carnitine (Krimberg), A., i, 342.

Oclusion and adsorption; nature of the so-called solid phase (Travers; Freundlich), A., ii, 18.

Ochoco fat (Lewkowitsch), A., ii, 885.

Ochronosis, the pathogenesis of (Gross and Allard), A., ii, 1053.

Ocimum ointile, oil from the leaves of (Goulding and Felly), P., 63.

cyclo-octa diene from ψ-pelletierine, constitution of, and its ozonides and polymerides (Harries), A., i, 254.

Octane, 8-amino-, and its salts and carbamides (Freylon), A., i, 861. hydroxy-. See 88-Dimethyl-8- and -8-hexanols.

See also 88-Dimethylhexane, 8-Methyl-γ-ethylpentane, and γ-isoPropylpentane.

cyclo-Octane, preparation and reduction of (Willstäetter and Kametaka), A., i, 401.

dicyclo-Octane, preparation and reduction of (Willstäetter and Kametaka), A., i, 402.

dicyclo-2:2:2-Octane, formation of (Semmler and Bartelt), A., i, 38.

Octanediacarboxylic acids. See 8-Methyl-α-ethylpmelic acid and α-Methyliso-propyldipic acids.

cyclo-Octanone. See Azelaone.

Octenyl alcohol. See 8-Methyl-Δ2-hepten-8-ol.

Octinene. See 8-Methyl-Δ8-heptadiene.

Octoic acid. See 8-isoPropylvaleric acid.

Octoic acid value of butter-fat, estimation of the (Dons), A., ii, 235.

Octopus, chemical investigations on the (Henne), A., ii, 517.

Octyl alcohols. See Dimethylisoamylcarbinol, 8-Methyl-γ-ethyl-β-pentanol, and γ-isoPropyl-β-pentanol.

5-Octyl-α-camphoramic acid (Freylon), A., i, 861.

Önanthaldioxide. See Heptaldioxide.

Oil from the roof of the Cockleshed coal seam, North Staffordshire (Hall), A., ii, 115.

Oils, catalytic reactions of oxidation and reduction of (Fokin), A., ii, 311. behaviour of, towards calcium carbonate (Künkler and Schwedhelm), A., ii, 494. which boil above 100°, apparatus for estimating the expansion of (Thörner), A., ii, 907. of the aromatic and fatty series, action of methyl sulphate on (Harrison and Perkin), A., ii, 135.

drying, radiation from (Schmidt), A., ii, 796.

essential and ethereal. See Oils, vegetable.

fatty, detection of "saccharin" in (Bianchi and Di Nola), A., ii, 440. lubricating, viscosity of (Mabery and Mathews), A., ii, 741.

mineral, optically active constituents of (Marcussen), A., ii, 384. optical activity of, in connexion with the question of their origin (Zaloziecki and Klarefeld), A., ii, 48. estimation of, in rosin spirit (Adan), A., ii, 1075. See also Naphtha and Petroleum.

phosphorised, estimation of phosphorus in (Wörner), A., ii, 629.

vegetable, constituents of (Semmler), A., i, 37, 92, 279, 483, 557, 558, 664, 784; (Semmler and Bartelt), A., i, 38, 194, 355, 901; (Charabot and Laloue), A., i, 196, 279; (Roure-Bertrand Fils), A., i, 558; (Haensel), A., i, 665; (Schimmel & Co.), A., i, 666.
Oils, vegetable, Japanese (KAMETAKA), A., i, 850.
reaction of phloroglucinol-hydrochloric acid with (KÖBERT), A., ii, 72.
detection of aldehydes or ketones in (ROTHENFUSSER), A., i, 52.
estimation of, in spices (REICH), A., ii, 1075.
Oleanol and its mono- and di-acetyl derivatives (POWER and TUTIN), T., 896; P., 117.
Oleasterol (POWER and TUTIN), T., 895; P., 117.
Olefines, action of ozone on (HARRIES and HAEFFNER), A., i, 846.
cyclic, action of ozone on (HARRIES and TANK), A., i, 517.
See also Hydrocarbons.
Oleic acid, catalytic reduction of (PAAL and ROTH), A., i, 590.
electrolytic reduction of, to stearic acid (MARIE), A., i, 244.
spectroscopic reaction for (LIFSCHUTZ), A., i, 263, 754.
ozonide, products of the decomposition of (MOLINARI and BAROSI), A., i, 849.
poisoning, chronic (FAUST), A., ii, 1062.
estimation of water in (DUBOVITZ), A., ii, 991.
Olenitol and its acetyl derivative (POWER and TUTIN), T., 914; P., 118.
Oleoureopine from Olea europaea (BOURQUELOT and VINTILESCO), A., i, 904.
Olehydroxamic acid (MORELL), A., i, 758.
Olestranol and its acetate and benzoate (POWER and TUTIN), T., 900; P., 117.
Oleum cadmium, sesquiterpene, C₄₉H₄₂O₅, in (LEFESCHKIN), A., i, 275, 557;
(SCHINDELMEISER), A., i, 353.
Oleum dracunculi. See Tarragon oil.
Olibanol (HAENSSEL), A., i, 665.
Olive, new glucoside from the (BOURQUELOT and VINTILESCO), A., i, 904.
Olive bark, constituents of (POWER and TUTIN), T., 904; P., 117.
Olive leaves, constituents of (POWER and TUTIN), T., 891; P., 117.
Onions, behaviour of, to stimulants (NAMBA), A., ii, 618.
Onocerio acid and Onocerin (onocerol) (v. HEMMELMAYR), A., i, 184.
Onoketone, dihydroxyz. and its diacetate and diphenylhydrzone (v. HEMMELMAYR), A., i, 185.
Opal, chaledony, and quartz, relation between (LEITMEIER), A., ii, 954.
Opalescence, critical (ROTHMUND), A., ii, 669.
Opianic acid, esters, nitration of (WEGSCHIEDE, MÜLLER, and CHIARI), A., i, 896.
Opianic acid, nitro-, methyl and ethyl esters, diacetates of, and sodium salt, and anhydride (WEGSCHIEDE, MÜLLER, and CHIARI), A., i, 896.
Opianylanilide (MEYER), A., i, 26.
Optical activity, inversion, isomerides, and properties, and Optically active compounds. See under Photochemistry.
Orcacetophenone dimethyl ether, reactions of (TAMBOR, BARANOWSKI, CUKIER, and TOMI), A., i, 358.
isOrcacetophenone methyl ethers (TAMBOR, BARANOWSKI, COMTETTE, and TOMI), A., i, 349.
Orcinol (2:5-dihydroxytoluene), azo-derivatives of (ORTON and EVERTT), T., 1019; P., 118.
dimethyl ether, aldehyde from, and its azine and phenylhydrzone, synthesis of (GATTERMANN), A., i, 34.
estimation of, in Orchella weed (WATT), A., ii, 739.
Ores, dry lead and silver assays in (LOEVY), A., ii, 323.
Organic chemistry. See under Chemistry.
Organic compounds, fluorescence of (STARK and STEUBING), A., ii, 911.
fluorescence and photo-electric sensitiveness of (STARK and STEUBING), A., ii, 746.
determination of the heat of combustion of, by the platinum resistance thermometer (FISCHER and WREDÉ), A., ii, 155.
action of hydrogen persulphide on (BRUNNER and VUILLEUMIER), A., i, 900.
catalytic dehydration of (SUNDERENS), A., i, 494.
viscosity of binary mixtures of (TSKALOTOS), A., ii, 260.
double compounds, with hydrogen peroxide (TANATAR), A., i, 399.
complex, decomposition of, in a variable magnetic field (ROSENTHAL), A., ii, 152.
cyclic, crystallography of (JAEGHER), A., i, 413.
mixed, relative volatility of certain groups of (HENRY), A., i, 305, 381.
unsaturated, catalytic reactions of oxidation and reduction of (FOKIN), A., i, 311.
Organic compounds, new method of estimating phosphorus in (Bay), A., ii, 531.
Pringsheim's method for estimating halogens in (Virgin), A., ii, 1070. estimation of halogens in (Baubigny), A., ii, 530.
estimation of active hydrogen in (Zerekwitinoff), A., i, 593.
estimation of sulphur in (Bay), A., ii, 319.
Organic mixtures, refractometric analysis of (Beythien and Hennicke), A., ii, 72 ; (Sundvik), A., ii, 990.
Organic substances, rotatory power of (Dewar and Jones), A., ii, 258.
fluorescence and colour of (V. Liebig), A., i, 445.
destruction of, in analysis (Kerbosch), A., ii, 981.
the Carrasco-Plancher method of estimating carbon and hydrogen in (Lenz), A., ii, 65.
estimation of metals in (Rothe), A., ii, 132.
Organism, theory of neutrality regulation in the (Henderson), A., ii, 487.
action of alcohol on the heat relationships of the (Harnack and laible), A., ii, 404.
degradation of aromatic substances in the human (Blum), A., ii, 1052.
substitution of bromine by chlorine in the (Boënger), A., ii, 208.
oxidation of phenyl derivatives of fatty acids in the (Dakin), A., ii, 720, 964.
passages of substances into the human, by osmosis (Kahlenberg), A., ii, 408.
growing, importance of calcium salts for the (Aron and Sebauer), A., ii, 208 ; (Aron and Frese), A., ii, 405 ; (Orgler), A., ii, 606, 872 ; (Aron), A., ii, 771.
Organometallic compounds, reducing properties of (Letellier), A., i, 242.
synthesis by means of (Zeltner), A., i, 401.
Organs, animal, estimation of the reducing power of (Wichern), A., ii, 1063.
Organanene and its derivatives from Cyprus organum oil (Pickles), T., 862 ; P., 91.
Organum oil from Cyprus, constituents of (Pickles), T., 862 ; P., 91.
Orites excelsa, aluminium in (Smith), A., ii, 885.
Orthobaric volumes in relation to pressure and temperature (Haigh ; Young), A., ii, 813.
Orthoclase and microcline, a chemical difference between (Babrier), A., ii, 704.
Orthoclase, analysis of (Babrier), A., ii, 704 ; (Babrier and Prost), A., ii, 863.
Osazones, melting point of certain (Fischier), A., i, 105.
a-Osazones, stereoisomeric, an alternative structure for the supposed (Chataway), P., 175.
Osmium (Makowka), A., ii, 393.
radiation of (Ledier), A., ii, 5.
wave-length tables of the arc and spark spectra of (British Association Reports), A., ii, 334.
Osmosis and Osmotic pressure. See under Diffusion.
Oven, electrically heated, with a liquid regulator (Ehrmann), A., ii, 1015.
Ovens, safety apparatus for (de Koninck), A., ii, 681
Oxalacetic acid, ethyl ester, action of, on benzylidene-β-naphthylamine (Simon and Mauguin), A., i, 296.
Oxalic acid, preparation of glycollic acid by the electrolytic reduction of (Deutsche Gold- & Silberscheide-Anstalt), A., i, 600.
and its potassium salt and water, equilibrium in the system (Koppel and Cahn), A., i, 852.
solutions and sodium carbonate, ready means of comparing (Tian), A., ii, 985.
Oxalic acid alkali salts, the carrying down of, by oxalates of the rare earths (Baxter and Daudt), A., i, 312.
ammonium potassium salt (Babrier), A., i, 601.
ammonium, thorium, and uranium salt (Evans), T., 663 ; P., 61.
calcium salt, occurrence of, in the barks of the Eucalyptus (Smith), A., ii, 885.
cerium, lanthanum, and samarium salts, solubility of, in dilute sulphuric and oxalic acids or their mixtures (Hauser and Wirth), A., ii, 778.
rare earth salts, solubility of, in solutions containing uranyl salts (Hauser), A., ii, 987.
cuprammonium salts (Horn and Graham), A., i, 392.
basic ferric salt (Rosenthaler and Siebeck), A., i, 246.
lanthanum salt, conversion of, into lanthanum sulphate by sulphuric acid (Wirth), A., ii, 570.
lead salt, decomposition of, by saline solutions (Cantoni and Mauri), A., i, 853.
complex ozotungsten salts (Mazzucchelli and Ingillerti), A., i, 756.
Oxalic acid, esters, action of zinc or magnesium on mixtures of, with esters of α-bromo-fatty acids (Rassow and Bauer), A., i, 316.

ethyl ester, condensation of, with acetone (Clark), A., i, 124.

action of dry ammonia on (Phelps, Weed, and Houssum), A., i, 11.

reduction of (Traube), A., i, 75.

Oxalic acid, dithio-α-ethyl ester (Staudinger), A., i, 983.

Oxalic aldehyde. See Glyoxal.

isoOxalines, isouinitroso-formation of, from furoxans (Wieland and Semper), A., i, 456.

Oxalosuccinonitrile, α-thyl ester, desmorytropy and fluorescence of, and its derivatives (Wislicents and Berg), A., i, 965.

Oxalyl chloride (Jones and Tasker), P., 271; (Staudinger), A., i, 983.

Oxanilideoxime-thiamide (Wieland and Mgelin), A., i, 1013.

isoOxazoles, new synthesis of (Schmidt and Widmann), A., i, 456.

Ox bile, constituents of (Langheld), A., ii, 211.

cholerin in (Salkowski), A., ii, 1055.

Ox blood. See under Blood.

Ox kidney, isolation of carnaubic acid from (Dunham), A., ii, 407.

Oxen, leucine from the ligamentum nuchae of (Samec), A., i, 231.

Oxidation and reduction of unsaturated organic compounds, catalytic reactions of (Fokin), A., i, 311.

by means of cuprous oxide in strongly alkaline solution (Ehrenfeld), A., ii, 848.

effected by ferric salts (Bongiovanni), A., i, 770.

by means of moulds (Herzog and Meier), A., ii, 1063.

by means of picric acid (Bacovescu), A., i, 825.

See also Autoxidation.

Oxidations of biological importance (v. Euler and Bolin), A., ii, 1021.

Oxides, function of, in catalysis (Ipatieff), A., ii, 266.

some, as tanning materials (Lüppochramer), A., i, 377.

of elements of the second group, crystallography of (Beckenkamp), A., ii, 280.

of refractory metals, silicon as a reducing agent for (Neumann), A., ii, 377.

acidic, heat of combination of, with sodium oxide (Mixter), A., ii, 929.

as-α-Oxides, organic, the order of the addition of ammonia to (Krassusky), A., i, 139.

Oxides. See also Metallic oxides.

Oxime formation, influence of acids and alkalis on the velocity of (Barrett and Lapworth), T., 85.

Oximes, formation of (Grassi), A., i, 800.

alkylation of (Irvine and Moodie), T., 102.

of the o-nitrotoluene series and their changes (Reissert), A., i, 983.

of sulphonic acids (Haga), A., i, 870; (Suzuki), A., i, 871.

See also Amino-oximes.

Oximino benzoylaminoxime and -formhydroxamic acid (Wieland and Semper), A., i, 108.

α-Oximino butyric acid, two forms of (Inglis and Knight), T., 1600; P., 191.

α-Oximino fatty acids, conductivities of the (Inglis and Knight), T., 1595; P., 191.

Oximino-α-nitrophenylpyruvic acid (Reissert), A., i, 983.

α-Oximinovaleric acid, two forms of (Inglis and Knight), T., 1600; P., 191.

α'-Oximino-β-vinylquinuclidine and its methiodide (Rabe and Buchholz), A., i, 100.

Oxomalonic acid, methyl ester, preparation of (Curtiss and Tarnowski), A., i, 760.

Oxonium salts, cyclic, from disalicylideneacetone and from spiropyran derivatives (Decker and Fleser), A., i, 906.

6-Oxy-2-allylimino-4-methyltetrahydro- pyrimidine and its isomerides (Majima), A., i, 223.

Oxyburseracin (v. Bolton), A., i, 436.

4-Oxy carbostyril, formation of, from o-nitrotolueneacetic acid (Matsubara), A., i, 915.

Oxy cellulose, reaction of, with Nessler's reagent (Ditz), A., i, 954.

cellulose, and hydrocellulose, highly nitrated (Berl and Klace), A., i, 504.

Oxycholestenediol. See Dehydrocholestenediol.

Oxy cholesterol, new reactions for (Golodetz), A., ii, 328.

Oxydase of Liberian coffee (Gorter), A., i, 346.

in Para rubber (Spence), A., ii, 774.

Oxydases, systematic investigation of (Dony-Hénault), A., i, 588.

in India rubber (Spence), A., ii, 616.
**Oxydases**, estimation of, in blood (Löb and Mulzer), A., ii, 958; (Löb), A., ii, 999.

Oxydiborodisulphosalicylic acid, sodium and sodio-potassium salts (Barthel), A., i, 271.

Oxydihydrotriazines and oxytriazines, attempts to obtain aliphatic substituted (Bilitz and Hornmann), A., i, 516.

2-Oxy-4:6-dimethylidihydropyrimidine. See Acetylacetonecarbamide.

6-Oxy-1:4-dimethyltetrahydropyrimidin-2-ino-, and its additive salts (Majima), A., i, 223.

6-Oxy-2-ethylthiol-4-methylpyrimidine-5-acetic acid, and its ethyl ester and potassium salt (Johnson and Heyl), A., i, 59.

**Oxygen**, atomic weight of (Leduc), A., ii, 271.

generation of, in a Kipp's apparatus (Wolter), A., ii, 1028.
spectra of, Doppler effect with canal rays (Stark), A., ii, 545.

and hydrogen, chemical action of radium emanation on (Cameron and Ramsay), T., 971; P., 132.

electrochemical equivalent of (Ehfeldt), A., ii, 559.

basic properties of (McIntosh), A., i, 596.

magnetic behaviour of air, argon, and helium in relation to (Tanzler), A., ii, 152.

polymeric forms of, constitution of (Erdmann), A., ii, 832.

absorption of, by electro-condensation products (Losanitsch), A., i, 846, 866; ii, 32.

simple form of apparatus for observing the rate of absorption of, by polluted waters and by other fermenting liquids (Adeney), A., ii, 781.

action of, on copper, tin, zinc, and the alloys of tin and zinc with copper (Jordis and Rosenhaupt), A., ii, 107.

action of, on metals (Jordis and Rosenhaupt), A., ii, 172.

interaction of, with nitric oxide (Mandl and Russ), A., ii, 272; (Holwech), A., ii, 941.

apparatus for the constant saturation of a liquid with (Luther and Plotnikoff), A., ii, 141.

resistance to lack of (Packard), A., ii, 402.

**Oxygen** and carbon dioxide, estimation of small quantities of, in small volumes of saline solutions (Brodie and Cullis); A., ii, 319.

**Oxygen carriers**, iron and heavy metals as (Cervello), A., i, 1027.

**Oxygen compounds**, quadrivalent, heat of formation of (McIntosh), A., ii, 355.

Oxyhaemocyanin, preparation and properties of, crystallised from the snail (Dere), A., i, 375.

**Oxyhaemoglobin**, behaviour of, towards reducing agents (Hüfner), A., i, 466.

**Oxyhydroxypridine** nitriles, hydrolysis of (Piccinini), A., i, 51, 679.

8-Oxy-7-indoxylaceneaphthene and its sulphonic acid (Bezdzik and Friedländer), A., i, 674; (Grob), A., i, 1011.

1-Oxy-2:(2')- and -2:(3')-indoxylacenaphthalenes (Bezdzik and Friedländer), A., i, 674.

1-Oxy-4methoxy-2:(2')-indoxylacenaphthalene (Bezdzik and Friedländer), A., i, 674.

6-Oxy-4methyl-1-allyltetrahydropyrimidine, 2-imino-, and its picrate (Majima), A., i, 223.

6-Oxy-2methylimino-4methylpyrimidine-5-acetic acid and its ethyl ester and potassium salt (Johnson and Heyl), A., i, 59.

**Oxyphenyldihydropyrimidine** and its platinichloride (Gabriel), A., i, 181.

2-Oxy-4methylpyrimidine, 6-amino-. See 4-Methylcytosine.

6-Oxy-4methylpyrimidine-5-acetic acid, 6-amino- (Johnson and Heyl), A., i, 59.

6-Oxy-2methylthiol-4-methylpyrimidine-5-acetic acid (Johnson and Heyl), A., i, 59.

6-Oxy-2-naphthalaminopyrimidine (Johnson, Storey, and McCollum), A., i, 838.

4:5-Oxy-1:2:5-osotriazoles (endoxypyr-rodiates), constitution of the (Ponzio), A., i, 1021.

8-Oxy-7-oxythionaphthylacenaphthene (Bezdzik and Friedländer), A., i, 674; (Grob), A., i, 1011.

**Oxyphenyldihydropyrimidine** and its platinichloride (Gabriel), A., i, 181.

2-Oxy-6-phenylmethylnamino-pyrimidine and -3-methylpyrimidine (Johnson and Clapp), A., i, 836.

2-Oxy-pyrimidine, 4-amino-. See Cytosine.

6-Oxy-pyrimidine, picrolonate of (Wheeler and Jamieson), A., i, 258.

6-Oxy-pyrimidine, 2-amino-. See iso-Cytosine.

6-Oxy-2-thio-3:5-dimethylpyrimidine (Johnson and Clapp), A., i, 835.
INDEX OF SUBJECTS.

3-Oxythionaphthen, preparation of (FARBWERKE vom. MEISTER, LUCIUS, & BRÜNING), A., i, 1008.

6-Oxy-2-o- and -p-toluidinopyrimidines (JOHNSON, STOREY, and MCCOLLUM), A., i, 837.

Oxytriazines and oxydihydrotriazines, attempts to obtain aliphatic substituted (BLITZ and HORRMANN), A., i, 516.

Ozone, atmospheric, origin of (HENRIET and BONYSSY), A., ii, 578.

formation of, by radium salts and emanation (NASINI and LEVI), A., ii, 793.

formation of, by the action of the electric discharge at low temperatures (BRINER and DURAND), A., ii, 101.

nitrogen peroxide, and hydrogen peroxide, formation of, in reactions in air which develop high temperatures (KEISER and McMÄSTER), A., ii, 223.

acid properties of (MANCHOT and KAMPSCHULTE), A., ii, 101.

compostion of, by light (WEIGERT), A., ii, 914.

thermal decomposition of (CLARKE and CHAPMAN), T., 1638; P., 190;

(PERMAN and GREAVES), A., ii, 480.

action of, on olefines (HARRIES and HAEZER), A., i, 846.

action of, on cyclic olefines (HARRIES and TANK), A., i, 517.

action of, on double and treble linkings (HARRIES), A., i, 75, 387;

(MOLINARI), A., i, 244, 849.

influence of, on the condensation of water vapour (LEITHÄUSER and POHL), A., ii, 372.

lecture experiments with (HARRIES), A., ii, 171.

nitrogen peroxide, and hydrogen peroxide, detection of, in gaseous mixtures (KEISER and MCMASTEr), A., ii, 222.

Ozonides of certain cyclic hydrocarbons, velocity of decomposition of (HARRIES and v. SPLAWA NEYMANN), A., i, 967.

decomposition of, by water (HARRIES and TANK), A., i, 517.

Palladium, atomic weight of (KEMMERER), A., ii, 1046.

new stage of oxidation of (WOHLER and MARTIN), A., ii, 392.

colloidal, reduction catalysis with (PAAL and GERUM; PAAL and ROTH), A., i, 599.

Palladium alloys with lead, nature of (PUSHIN and PASHSKY), A., ii, 860.

Palladium hydride (PAAL and GERUM), A., ii, 392.

liquid hydrosol of (PAAL and GERUM), A., ii, 392.

silicides (LEBEAU and JOLIBOIS), A., ii, 602.

Palmatine and its derivatives from calumba root (FEIST), A., i, 101.

Palmitin-8-naphthalide, amino-, reaction of, with diazo-salts (SULZBERGER), A., i, 483.

Palmitohydroxamic acid (MORELLI), A., i, 758.

Pancreas, secretory activity of the, under the influence of hydrochloric acid and intestinal extract (POPIELSKI), A., ii, 119.

a new function of the, and its relation to Diabetes mellitus (LOEWI), A., ii, 712.

putrefying, new base from (ACKERMANN), A., i, 1007.

guanylic acid from the (STEUDEL), A., i, 70; (v. FÜRTH and JERUSALEM), A., ii, 119.

nucleic acid of the. See under Nucleic acids.

Pancreatic diabetes. See Diabetes.

Pancreatic juice, variations in the proteolytic activity of (CAMUS and GLEY), A., ii, 205.

action of the amylase of, and its activation by gastric juice (BIER), A., ii, 305.

Panicum stagninum ("bourbon") from Upper Senegal (PERROT and TASSILLY), A., ii, 726.

Pantogen, determination of the atomic weight of (HINRICHES), A., ii, 1027.

Papaverine, phenolbetaines from (DECKER, DUNANT, and GIRARD), A., i, 204.

quaternary salts (DECKER and DUNANT), A., i, 206.

Paraffin wax from the Ladysmith Pit, Whitehaven Collieries (BEDSON), A., ii, 115.

Paraffins, higher normal, fractional distillation of, from lignite in the vacuum of the cathode light (KRAFFT), A., i, 1.

See also Hydrocarbons.
Parahopite from Rhodesia (SPENCER), A., ii, 397.

Paralactic acid. See d-Lactic acid.

Paramecia, the point of attack of photosynthetic substances in (V. Tappeiner, Osthelder, and Erhardt), A., ii, 867.

Paranormaldehyde (Molinari and Barosi), A., ii, 850.

Paranucleic acid. See Polypeptide-photophoric acid.

Parasaccharin, C₅-sugars from (Kilian), A., i, 135.

dl-Parasaccharinic acid, brucine salt and phenylhydrazide (Nef), A., i, 8.

Paratooite from Elder Rock, South Australia (Mawson and Cooke), A., ii, 398.

Parasite, composition of (Tscherne), A., ii, 862.

Parkeia biglobosa, pulp of (Goris and Crete), A., ii, 218.

Parsley, French, essential oil of, and the contained ether (Thoms), A., i, 902.

Parthenogenesis, isotonic and isosmotic solutions in (Delage), A., ii, 305.

Passivity, review of the various theories of (Fredenhagen), A., ii, 679.

of metals (Byers), A., ii, 1026.

Pastilles, estimation of mercuric chloride in (Saporetti), A., ii, 133; (Rimini), A., ii, 433; (Flora), A., ii, 735.

Pastry, action of heat on the lecithin phosphoric acid contained in (Ludwig), A., ii, 744.

Pasture land, manural experiments on (Solberg), A., ii, 422.

Pathological fluids, molecular concentration of (Javal), A., ii, 716.

organs, double refracting substances from (Panzier), A., ii, 122.

Pea, legumelin and vicilin from. See Legumelin and Vicilin.

Peas, continuous growth of, on the same soil (Suzuki), A., ii, 617.

Peat, Indiana, chemical examination and calorimetric test of (Lyons and Carpenter), A., ii, 890.
INDEX OF SUBJECTS.

CycloPentanonecarboxylic acid, ethyl ester, preparation of (Bouveault and Locquin), A., i, 393.

CycloPentanone-3-carboxylic acid, ethyl ester, and the action of magnesium methyl iodide on (Haworth and Perkin), T., 591.

CycloPentanonecarbinol and its phenylcarbamate and corresponding aldehyde (Zelinsky), A., i, 727.

Pentaphenylhydrazine hydrodiodides and hydrobromides (Lockemann and Weiniger), A., i, 916.

CycloPentene ozonide, conversion of, into the mono- and di-aldheydes of glutaric acid (Harries and tank), A., i, 517.

Δβ-Penten-5-ol and its chloride (Reif), A., i, 847.

Δ₁-cycloPenten-1-ol, acetate of (Mannich and Hangu), A., i, 276.

Pentosans, production and physiological role of, in plants (Calabresi), A., ii, 217.

Pentose-osazone from inosine (Haisser and Wennzel), A., i, 522.

Pentoses, test for, with orcinol and hydrochloric acid (Pieraerts), A., ii, 903.

estimation of, in urine (Jolles), A., ii, 235.

Pentosuria, a case of chronic (Luzzatto), A., ii, 1059.

Pepsin, constituents of (Huguon enq and Morel), A., i, 744.

and chymosin (Gewin), A., i, 71; (Bang), A., ii, 236.

non-identity of, with rennin (Hamburger), A., i, 588.

estimation of, by means of edestin (Fuld and Levison), A., ii, 76.

Peptides. See Amino-acids, Dipeptides, and Polypeptides.

Peptone, Witte's, hydrolysis of (Leven and van Slyke), A., i, 932.

Peptones, albumoses, and glycine, isolation of, from dilute aqueous solutions (Stiegfried), A., i, 234.

from protein (Rogosinski), A., i, 437.

Percarbonates (Wolffenstein and Peltyn), A., ii, 180, 183; (Merck), A., ii, 180.

Perchlorates. See under Chlorine.

Perhalogen salts, studies of the (Tinkler), T., 1611; P., 191.

Perhydroxide bases and their salts, preparation of (Wolffenstein), A., ii, 830.

Perilla, oil of (Kametaka), A., i, 851.

Periodates. See under Iodine.

Permanganate solutions. See under Manganese.

Peroxidase, purification of (Bach and Tscherniack), A., i, 746.

behaviour of, towards light (Bach), A., i, 238; (Jamada and Jodlbauer), A., i, 239.

Peroxidases from beetroot (Ernest and Berger), A., i, 72.

of animal tissues (Batelli and Stern), A., ii, 964.

artificial (peroxydiasates), and the important role of iron in their action (Wolff), A., i, 137, 490; ii, 573, 1022; (Wolff and de Stoeklin), A., i, 746.

Persenilose, a new crystalline sugar with seven carbon atoms, and its osazone (Bertrand), A., i, 715.

Perstannates. See under Tin.

Persulphuric acid and Persulphates. See under Sulphur.

Petroleum, Roumanian, radioactivity of (Hurmuzescu), A., ii, 453.

new reaction of (Molinari and Fenaroli), A., ii, 933.

See also Naphtha and Oils, mineral.

Phaeophytin and chlorophyllan (Tsvett), A., i, 668.

Phaeophorbin (Willstätter and Benz), A., i, 199.

Phagocytosis, researches in (Hamburger and Hekma), A., ii, 205, 510.

influence of hæmoglobin, &c, on (Hamburger and Hekma), A., ii, 511.

Pharmacological action of certain lactones and the corresponding hydroxy-acids (Marshall), A., ii, 1060.

significance of twin ethyl groups (Frankel), A., ii, 1060.

Phase rule. See under Equilibrium.

Phaseolunatase and its actions (Auld), T., 1253.

Phellandrene from water fennel oil (Kondakoff), A., i, 665.

α-Phellandrene, synthesis of (Wallach and Heyer), A., i, 425.

Phenacylacetio acid, cyano-. See β-Benzoylpropiionic acid, α-cyano-.

Phenacylacetoacetic acid, ethyl ester, action of hydrazine on (Paal and Kühn), A., i, 57; (Bülow and Filchner), A., i, 578.

Phenacylammonium salts, quaternary (Weidekind), A., ii, 875.

Phenacylbenzoylacetio acid, ethyl ester, action of hydrazine on (Paal and Kühn), A., i, 57.

monohydrazone of (Paal and Kühn), A., i, 57.
Phenacyl-dialuric acid, -isoxydantioic acid, and -tartronic acid and its salts (KÜHLING), A., i, 571.

Phenacylphenylidialkylammonium salts (Wedekind), A., i, 578.

Phenantherafluranza, 2:7-dibromo- (Schmidt and Mezger), A., i, 16. 3-nitro- (Schmidt and SÖLL), A., i, 996.

Phenantheraphenazine (Schmidt and SÖLL), A., i, 995.

9:10-Phenantheraquinoine, synthesis of, and its salts (Herschmann), A., i, 683.

Phenantheraquinoine, ditertiary alcohols from (Zincck and Tropp), A., i, 786.

metallic haloids (Meyer), A., i, 731.

Phenantheraquinoine, 3-amino- and its oxime (Schmidt and SÖLL), A., i, 997.

diazoisation of (Schmidt and SÖLL), A., i, 995.

2:7-dibromo- and its dioxime and its diacetyl derivative (Schmidt and Mezger), A., i, 16.

3:4-dihydroxy-. See Morpholquinone.

3-nitro-, and its monoamine, dioxime and its diacetyl derivative and dimethyl ether, and semicarbazone (Schmidt and SÖLL), A., i, 996.

Phenantherene and its hydro-derivatives, pharmacology of (Hildebrandt), A., ii, 876.

oxidation of (Law and Perkin), T., 1637.

reduction of, in presence of nickel oxide (Ipatieff, Jakowleff, and Rakitin), A., i, 330.

styphnate (Gibson), T., 2099; P., 241.

3:9:10-triamino-, and its hexa-acetyl derivative, and chloroaminohydroxy-derivatives (Schmidt and SÖLL), A., i, 997.

9-bromo-, picrate of (Schmidt and Mezger), A., i, 16.

2:7-dibromo- (Schmidt and Mezger), A., i, 16.

Phenantherene series (Schmidt and Mezger), A., i, 16; (Schmidt and SÖLL), A., i, 995, 996.

Phenantheroanthraquinone, preparation of (Farbwirke vorm. Meister, Lucius, & Brüning), A., i, 808.

Phenanthrone, 9:9- and 10:10-dichloro-3-nitro- (Schmidt and SÖLL), A., i, 997.

Phenazine-2:7-bisarsonic acid and its tetrasodium salt (Barrowcliff, Pyman, and Remfry), T., 1900.

Phenazines, hydroxy-, interaction of, with sodium sulphide (Farbwirke vorm. Meister, Lucius, & Brüning), A., i, 219.

Phenylnitrobenzoic acid. See 1:3:5-Triphenylbenzene-2':2''':2''''-tricarbolic acid.

p-Phenetidinesulphonic acid, 2-chloro-azo-derivative of (Aktien-Gesellschaft für Anilin-Fabrikation), A., i, 1023.

Pheneteole, sulphination of (Smiles and Le Rossignol), T., 756.

Pheneteole, 2:3- trilogy- and 2:3:4-tri-nitro-, and 2:4-dinitro-3-hydroxy- (Blanksma), A., i, 157.

3- and 4-nitro-2-cyano- and 4:6-dinitro-2-cyano- (Blanksma), A., i, 978.

3:4-dinitro-2-cyano- (Blanksma), A., i, 271.

S-Phenetyl-N-methyl-3:9-dinitrophenylationium hydroxide and salts (Smiles and Hilditch), T., 152.

S-Phenetyl-3:9-dinitrophenazothionium hydroxide and salts (Smiles and Hilditch), T., 149.

S-Phenetylphenoazothionium hydroxide, a-3:9-dinitro- (Smiles and Hilditch), T., 1694.

p-Phenetylsulphinic acid, alkaloidal salts, and their rotatory power (Hilditch), T., 1621.

p-Phenetylsulphonic acid, alkaloidal salts, and their rotatory power (Hilditch), T., 1621.

S-Phenethylthionine and its hydroxide and salts (Smiles and Hilditch), T., 1695.

Phenylyl. See also Ethoxybenzene- and Ethoxyphenyl-.

Phenol, preparation of, from cyclohexanol (Kötz and Götz), A., i, 173.

and cyclohexanol, mutual solubility of (Mascalatti and Pestalozza), A., i, 527.

freezing point surfaces of the system, chlorobenzene, naphthalene, and, and the molecular association of (Hirobe), A., ii, 928.

freezing point curves of mixtures of naphthalene and (Yamamoto), A., ii, 928.

condensation of, with fatty aldehydes (Lunjak), A., i, 416.

combination of, with benzil (v. Liebig and Krém), A., i, 449.

condensation of, with epichlorhydrin (Boyd and Marle), T., 838; P., 92.
Phenol derivatives containing a mobile nitro-group, syntheses with (MELDOLA and HAY), T., 1559; P., 197.

Phenol, p-amino-, sulphurous acid compound of (SOCIETÉ ANONYME DES PLAGUES ET PAPIERS PHOTOGRAPHIQUES, A. LUMIÈRE ET SES FILS), A., i, 977.

4:6-N-diacyl derivative of, and its diazo-compound (CASSELLA & CO.), A., i, 457.

trichloro-, phenylurethane of (VALLEE), A., i, 976.

2-bromo-4:6-dinitro- and 2:6-dibromo-4-nitro- (ZINCKE and GOLDEMANN), A., i, 789.

o- and p-chloro-, and o- and p-nitro-, compounds of, with phenylcarbimide (MICHAEL and COBB), A., i, 949.

m- and p-chloro-, coumarins from (CLAYTON), T., 2021.

2:4:6-trichloro-, and its transformation into chlorinated benzoquinones (LÉGER), A., i, 335.

haloid derivatives, coloured and colourless silver salts of (HANTZSCH and SCHRÖTER), A., i, 17.

2:4-dinitro-, two chemically isomeric (V. OSTROMISLÉNSKY), A., i, 468.

3:4:6-trinitro-.. See Picric acid.

6-nitro-2:4-diamino-, 2:4-N-diacyl derivative of (CASSELLA & CO.), A., i, 458.

2:3:5-trinitro-4-amino-, N-acetyl derivative of, interaction of, with amines (MELDOLA and HAY), T., 1659; P., 197.

molecular compound of, with β-naphthol (MELDOLA and HAY), P., 210.

thio-.. See Phenyl mercaptan.

See also Carbolic acid.

Phenolic ethers, hydrolysis of (STÖRMER, FRIDENICI, and ALTGELT), A., i, 190.

sulphination of, and the influence of substituents on (SMILES and LE ROSSIGNOL), T., 745; P., 61.

containing the ψ-allyl side-chain, "CMe:CH₂, preparation, properties, and nomenclature of (BÉHAL and TIFFENEAU), A., i, 261, 630.

Phenolic ethers containing the propenyl (isallylic) group, synthesis of (BÉHAL and TIFFENEAU), A., i, 260.

Phenols and their derivatives, action of ammonia on (KORCZYŃSKI), A., i, 977.

containing the propenyl group, synthesis of (BÉHAL and TIFFENEAU), A., i, 260.

and acids, comparative experiments on the basicity and strength of (THIEL and RÖMER), A., i, 787.

acetylation of (SMITH and ORTON), T., 1247.

action of bromine and chlorine on (ZINCKE and GOLDEMANN), A., i, 780; (ZINCKE and BIRCHSEL), A., i, 781.

reaction of, with diazonium salts (ORTON and EVERATT), T., 1010; P., 118.

action of iodine on (GARDNER and HODGSON), P., 273.

reaction of, with phosphorus pentachloride (AUTENRIETH and GEVER), A., i, 156.

reaction of, with sodium hypobromite (DEHN and SCOTT), A., i, 780.

comparative study of, as agents in parthenogenesis (DELAGE and DE BEAUCHAMP), A., ii, 51.

alkali-insoluble (TORREY and KIPPER), A., i, 460.

azo-derivatives of (GRANDMOUGIN and FREIMANN), A., i, 1023.

the iodine value of (WAKE and INGLE), A., i, 416.

colour reactions of, with organic acids (FENTON and BARR), A., ii, 438.

Messinger and Vortmann’s method of estimating (BOUGAIL), A., ii, 738.

Phenols, p-amino-, maleic and fumaric derivatives of (PIUTTI), A., i, 783.

bromo- and chloro-, behaviour of, with potassium hydroxide, zinc bromide and chloride, sulphuric acid, potassium carbonate, and potassium acetate (TYMSTRA), A., i, 262.

See also Polyphenols.

Phenolbetaines from papaverine (DECKER, DUNANT and GIRARD), A., i, 294.

Phenolcarboxylic acid, strength of the second stage of the dissociation of (LEV and EKLER), A., i, 177; (OBERMILLER), A., i, 634; (THIEL), A., i, 791.

Phenolcarboxylic acids, azo-derivatives of (GRANDMOUGIN and FREIMANN), A., i, 1023.

methyl-carbonato-derivatives of, and their use for synthetical operations (FISCHER), A., i, 892.
Phenolphthalein, change of colour of (WEGSCHEIDER and SCHUGOWITSCH), A., ii, 806.

dissociation of (HILDEBRAND), A., ii, 646.

purgative action of, and of its disodium derivative (FLEIG), A., ii, 313.

use of, in the titration of acids in presence of sulphurous acid (POZZI-ESCO), A., ii, 628.

sodium and potassium salts (MEYER and MARX), A., i, 652.

Phenolsulphonic acid and its salts, estimation of (Hübener), A., ii, 641.

Phenolsulphonic acid, p-amino- (BRUNNER and VUILLEUMIER), A., i, 879.

2-amino-, arylsulphonates of (CASSELA & Co.), A., i, 785.

2-6-dibromo-, methyl and ethyl esters and sulphalnilide of (ZINCKE and BRUN), A., i, 336.

2-chloro-3-nitro-6-amino-, preparation of (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 785.

Phenol-5-sulphonic acid, 2-amino-, and its diazo-derivative, preparation of (CASSELA & Co.), A., i, 785.

Phenolsulphonnic acids, conditions of formation of (OBERMILLER), A., i, 260.

acidity of the different (LEY and ERLER), A., i, 177; (OBERMILLER), A., i, 654.

strength of the second stage of the dissociation of (THIEL), A., i, 791.

action of phosphorus chlorides on (ANSCHTZ), A., ii, 83.

Phenolsulphonic acids, o- and p-, copper salts, and the action of ammonia and pyridine on (LEY and ERLER), A., i, 177.

Phenol-4-sulphonic acids, 3-nitro-6-amino-, preparation of (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 785.

1-2-Phenonaphthacarbazole-N-sulphonic acid and its barium and sodium salts (BÜCHERER and SEYDE), A., i, 455.

Phenophenanthracridine, preparation of (AUSTIN), T., 1765; P., 200.

Phenorosamine, diacetyl derivative chloride of (KEHRMANN and DENGLER), A., i, 1002.

Phenoxazin derivatives, preparation of (AKTIEN-GESELLSCHAFT FÜR ANILIN-FABRIKATION), A., i, 1010.

Phenoxide, ammonium (BÜCHL), A., i, 259.

Phenoxide, 2:4:6-triiodo-, basic bismuth salts (CARRASCO), A., i, 336.

Phenoxides, alkalii, action of chloro-methyl ether on (REYCHLER), A., i, 158.

4-Phenoxynaphthaldehyde and its azine, oxime, and phenylhydrazine, synthesis of (GATTERMANN), A., i, 33.

Phenoxylvichloropropane (BOYD and MAIRLE), T., 841; P., 92.

Phenoxypentamethylylphosphonium salts (BARNETT and SMILES), P., 123.

Phenoxypentamethylylphosphonium salts (BARNETT and SMILES), P., 124.

4-Phenoxo-3-methyltritaneic acid and its anhydride (V. LIEBIG), A., i, 541.

α-Phenoxypine, γ-chloro-β-hydroxy- (FISCHER and KRÄMER), A., i, 858.

β-Phenoxo-β-2,5-quinoxylisobutyric acid, α-4:2'-5'-tetrahydroxy-, formation of (ENGELS, PERKIN, and ROBINSON), T., 1155.

5-Phenoxo-γ-valerolactone and its carbocyclic acid and their bromo-derivatives (FISCHER and KRÄMER), A., i, 858.

5-Phenoxo-γ-valerolactone, bromo-α-amino-, and its hydrobromide and hydrochloride (FISCHER and KRÄMER), A., i, 858.

Phenyl, transposition of, in aromatic iodohydrins (TIFFENEAU), A., i, 165, 166; (TIFFENEAU and DAUDEL), A., i, 972.

Phenyl arsene (LANG, MACKEY, and GORTNER), T., 1369; P., 150.

benzyl sulphide (FROMM and ROESICKE), A., i, 968.

ethyl ether. See Phentole.

glycide ether and its reactions (BOYD and MAIRLE), T., 840; P., 92.

mercaptan, action of aluminium chloride on (DEUSS), A., i, 530.

p-nitro-, derivatives of (FROMM and WITTMANN), A., i, 631.

methyl ether. See Anisole.

Phenylacetamide, o- and α-bromo- (STEINKOPF and BENEDEN), A., i, 981.

c-nitro- (REISSERT), A., i, 983.
INDEX OF SUBJECTS.

Phenylacet-anilide, \(-\text{o}, -\text{m}, \text{and} -\text{p}\)-toluidides and \(\text{-phenylhydrazide, \(\text{a}\)-cyano-} \) (Hessler), A., i, 183.

Phenylacetic acid, bruine and cichonine salts, and their optical activity (Hilditch), T., 1390.

Phenylacetic acid, amino-, resolution of, into optically active constituents and its \(N\)-formyl derivatives (Fischer and Weichhold), A., i, 419.

\(\alpha\)-amino-, optical resolution of (Ehrlich and Wendel), A., i, 269; (Betti and Mayer), A., i, 639.

\(\alpha\)-amino-, and its hydrochloride, phenylcarbimide, phenylhydantoin and \(\beta\)-diphenylhydantoin (Ehrlich and Wendel), A., i, 269.

Phenylacetazonine, \(\text{isonitroso-} \) (Ponzio and Giovetti), A., i, 834.

\(\alpha\)-Phenylacetone, \(\alpha\)-amino-, and its salts (Gabriel and Lieck), A., i, 406.

Phenylacetonic acid (benzoy cyanide), sodium, action of, on ethyl cinnamate (Avery and McDoile), A., i, 343.

Phenyl-\(\text{p}\)-acetylaminotolyliodonium hydroxide and salts (Willgerodt and Gardner), A., i, 877.

Phenylalanine, 3:5-\(\text{dibromo-} \) and its ethyl ester and salts (Wheeler and Clapp), A., i, 897.

\(\beta\)-iodo-, and its derivatives (Wheeler and Clapp), A., i, 981.

Phenylallyltio carbamids, reactions of, with acyl chlorides (Dixon and Taylor), T., 24.

Phenylamino-. See Anilino-.

Phenyl-p-aminobenzeneazo-\(\beta\)-naphthol and its 2- and 4-\(\text{mono-} \), 2:4-\(\text{dii-} \) and 2:4:6-\(\text{tri-nitro-derivatives} \) (Morgan and Mickelthwait), T., 609; P., 48.

Phenyl-p-aminobenzediazonium chloride, 2:4-\(\text{dinitro-} \) (Morgan and Mickelthwait), T., 610.

Phenylaminodimethylcarbinol and its dibenzoyl derivative (Riedel), A., i, 769.

\(\beta\)-Phenyl-1-\(\text{o}, -\text{m}, \text{and} -\text{p}\)-amino- and \(\beta\)-nitro-phenyl-2-methylpyrrolo-3-carboxylic acids, ethyl esters (Borsche and Titsnig), A., i, 104.

1-Phenyl-5-aminophenylaminotriazole, 3-thio-, and its diacetyl and dibenzylidene derivatives (Fromm and Baumhauer), A., i, 702.

\(\alpha\)-Phenyl-\(\beta\)-anisylethylthiocarbamide (Busch and Leeffhelm), A., i, 153.

\(\beta\)-Phenyl-\(\beta\)-anislyhydracrylic acid and its ethyl ester and barium salt (Stoermer and Friderici), A., i, 180.

Phenylnalsylidene-\(\beta\)-phenylenediamine and its hydrochlorides (Moore and Woodbridge), A., i, 686.

Phenylnalsylidoethyline (Stoermer and Friderici), A., i, 179.

\(\beta\)-Phenyl-\(\beta\)-anislypropionic acid (Stoermer and Friderici), A., i, 179.

Phenylnalsinic acid (phenylarsenic acid) and \(\beta\)-chloro- and \(\beta\)-hydroxy- (Bertheim), A., i, 591.

\(\beta\)-amino- (arsenitic acid), preparation of derivatives of (Kuratorium der Georg und Franziska Speyerschen Studienstiftung), A., i, 591, 747.

homologues and derivatives of (Benda and Kahn), A., i, 591. sodium salt. See Atoxyl under Arsenic.

\(\alpha\)-amino-, an isomeric (Bertheim), A., i, 590.

\(\beta\)-hydroxy- (Barrowcliff, Pyman, and Kempfry), T., 1895.

\(\beta\)-iodo-, biochemical investigations of (Blumenthal and Herschmann), A., ii, 878.

2-Phenylnalsimobenzene, 4'-hydroxy- (Ullmann and Fukin), A., i, 298.

Phenylnalsoacetacetic acid, ethyl ester, benzoylhydrazone of, and the action of alkali on (Bülow and Schaub), A., i, 705.

\(\gamma\)-Phenylnalsoglutaconic acid, ethyl ester, phenylhydrazone of (Henrich and Thomas), A., i, 114.

Phenylnalzo-. See also Benzeneazo-.

1-Phenyl-5-benzeneazo-6-pyridazone-3-carboxylic acid, ethyl ester (Henrich and Thomas), A., i, 114.

2-Phenylnalsopyranol(1:4), 7-hydroxy- anhydrohydrochloride and platini chloride of (Perkin and Robinson), T., 1098.

2-Phenylnalzotriazine, imino-\(\text{m\-cyano-} \) amino-, and its hydrochloride (Pirkon), A., i, 925.

2-Phenyl-1:2:3-benzotriazole, 5-amino-, change of the colour of fluorescence of, with the solvent (Ley and V. Engelhardt), A., ii, 746.

Phenyl \(\alpha\)-benzoylphenyl-\(\alpha\)-phenyl-\(\alpha\)-propyl ketone (Kohler), A., i, 777.

Phenylnalbenzyllidenehydrazine (Michaelis), A., i, 471; (Goldschmidt), A., i, 572.

Phenylnalsythylpropylsilicane, sulphonation of (Marsden and Kippino), T., 203; P., 12.

\(\beta\)-Phenylnalsyhydrazine and its hydrochloride (Ponzio and Valente), A., i, 468.
β-Phenylbenzylhydrazine, and its salts, and acyl derivatives and their nitroso-derivatives (Schlenk), A., i, 757.

α-Phenylbenzylhydrazine, action of, on carbamide (Milrath), A., i, 551.

p-Phenylbenzylideneaminom-α-alkylcinnamic acids, esters, and their liquid crystals (Vorländer and Kasten), A., i, 641.

Phenylbenzylideneethylthiosemicarbazide (Michaelis and Hadanc), A., i, 1020.

1-Phenyl-4-benzylidene-α-cyclometene-3-one and its 4-o-hydroxy- and -dimethylamino-derivatives (Borsche and Menz), A., i, 148.

Phenylbenzylidene-p-phenylenediamine, hydrochlorides of (Moore and Woodbridge), A., i, 636.

Phenylbenzylmethyllallylammonium salts, p-bromo-, optical activity of (Everatt), T., 1236; P., 148.

PhenylbenzylmethyImine, p-bromo- (Everatt), T., 1238.

Phenylbenzylmethyl-p-butyrammonium salts, p-bromo-, optical activity of (Everatt), T., 1238; P., 148.

β-Phenyl-β-butyric acid, synthesis of and its amide and anilide (Eykmam), A., i, 795.

γ-Phenylbutyric acid, α-cyano-γ-hydroxy-, and its lactone (Bougault), A., i, 422.

β-imino-α-cyano-, and its ethyl ester (Best and Thorpe), P., 283.

β-iodo-γ-hydroxy-, and β-iodo-α-γ-dihydroxy-, lactones of (Bougault), A., i, 538.

Phenylbutyric acids, α-, β-, and γ-, synthesis of (Eykmam), A., i, 23.

Phenylearbcamic acid, o-chlorophenyl ester (Michael and Cobb), A., i, 949.

Phenylcarbamide, amino- (phenylsemicarbazide), reactions of (Rolla), A., i, 473.

β- and p-cyanoamino- (Pierron), A., i, 925.

Phenylcarbimide, reactions of (Vallee), A., i, 976.

formation of carbodiphenylimide from (Stolle), A., i, 415.

as reagent for determining the constitution of merotropc compounds (Michael and Cobb), A., i, 947.

3-Phenylearbcostyril (HüBner), A., i, 288.

2-Phenylisoscarboystyril-4-carboxylic acid, and its ethyl ester (Dieckmann and Meiser), A., i, 895.

Phenylearbcylamine from nitrobenzene and from pyrogallol (Brunner and Vuilleumier), A., i, 878.

γ-Phenylchloroacetic acid, resolution of (McKenzie and Clough), T., 818; P., 91.

β-Phenylchloroacetic acid, displacement of halogen in, by hydroxy- and methoxy-groups (McKenzie and Clough), T., 811; P., 91.

Phenylchloroiso-α-propyl alcohol and its acyl derivatives (Fourneau and Tiffenaui), A., i, 163.

3-Phenyleinonic acid and its derivatives (Hübner), A., i, 288.

β-Phenyleinonic acid (β-di-phenylacrylic acid) and its salts (Rupe and Busolt), A., i, 23.

Phenyleinonamylen-p-phenylenediamine and its hydrochlorides (Moore and Woodbridge), A., i, 686.

α-Phenyleinonamylideneacetic acid, methyl ester, reaction of, with organic magnesium compounds (Reimer and Reynolds), A., i, 988.

β-Phenylcoumarin (Stoermer and Faberici), A., i, 180.
Phenylisocrotonic acid, volumetric esti-
mation of (BOUGAULT), A., i, 983.
Phenylisocerophenone and its oxime and
O-benzoyl derivative (WIELAND and
STENZL), A., i, 35.
Phenylcyanamide, p-iodo-, and the
carbamide (PIERRON), A., i, 925.
N-Phenyldiacetonitrile and its phenyl-
hydrazone derivative, and m- and p-
chloro- and p-hydroxy-derivatives (V.
MEYER and SCHUMACHER), A., i, 909.
9-Phenylidibenzopyronium and its deri-
atives (DECKER and FELSE), A., i, 1003.
Phenylidibenzalazinium bromide (PON-
ZIO and VALENTE), A., i, 458.
1-Phenyl-2:4-dibenzylidene-cyclopeptan-
3-one (BORSCH and MENZ), A., i, 149.
8-Phenylidihydrocampholic acid, syn-
thesis of (EYKMAN), A., i, 23.
Phenylidihydrosulfoarsonic acid, syn-
thesis of (EYKMAN), A., i, 23.
2-Phenylidihydronephthiatrazine, imino-
hydrochloride of (PIERRON), A., i, 926.
Phenylidimethyl-n-butylammonium
iodide, p-bromo-(EVERATT), T., 1233.
Phenylidimethylcarbinol, amino- (RIE-
DEL), A., i, 251.
Phenylidimethylenomethylammonium
iodide (V. BRAUN), A., i, 628.
4-Phenyl-1:1-dimethylcyclohexane-2:6-
dione and its dioxime and diphenyl-
hydrazone, and its 3:5-dicarboxylic
acid, ethyl ester, and its reactions
(DIECKMANN and KRON), A., i, 388.
3 Phenyl-5:5-dimethylhydanto
tin (BAILEY and RANDOLPH), A., i, 742.
and 1-amino-, and its benzylidene
derivative (BAILEY and BROOKS), A., i, 842.
1-Phenyl-2:3-dimethyl-5-pyrazoline.
See Antipyrine.
1-Phenyl-3:5-dimethyl-3-thiopyrazolone,
p-bromo- (MICHAELIS and STIEGLER),
A., i, 212.
s-Phenyldiphenylhydrazine, transfor-
mation of (DZIUHANDZINSKI), A., i, 696.
3-Phenylenecetopropionic acid (MOORE
and THORPE), T., 182; P., 13.
Phenylenedisdiacetonitriles, a-, m-, and
p- (V. MEYER and SCHUMACHER), A., i,
910.
a-Phenylideniacetic acid and its amide
and nitrile, preparation of (MOORE
and THORPE), T., 175.
Phenylen-1:3-diamine, 2:4-dinitro-
(KORNER and CONTARDI), A., i, 524.
p-Phenylenediamine, condensation of,
with aldehydes and ketones (ROTHEN-
FUSER), A., i, 52.
XCIV. ii.

P-Phenylenediamine, sulphurous acid
compound of (SOCIETE ANONYME
DES PLAQUES ET PAPIERS PHOTO-
GRAPHIQUES, A. LUMIERE ET SES
FILS), A., i, 977.
nitrates (SCHALL), A., i, 239.
1:2-Phenylenediazio-oxide 4-chloro-5-
nitro- (FARBENFABRIKEN VORM. F.
BAYER & CO.), A., i, 230.
m-Phenylenedicyanamide (PIERRON),
A., i, 925.
m-Phenylenedimethylidiamine. See 1:3-
Dimethylaminobenzene.
a-Phenyleneguanidine and its benz-
yl derivative (PIERRON), A., i, 926.
Phenylenoazamide (MOTYLOWSKI), A.,
i, 371; (HINSBERG), A., i, 694.
m-Phenylenetramethylidiamine, new
derivatives of (SACHS and APPEN-
ZELLER), A., i, 227.
Phenylethenylaminooxime, hydroxy-
(CONDUCHE), A., i, 155.
Phenylethylaminocacetanitrite, p-bromo-
and its platinichloride and methiodide
(V. BRAUN), A., i, 626.
Phenylethylene amylidohydrin, ethyl-
idohydrin, glycol o-methyl and
o-ethyl ethers of, iodohydrin, and
methylidohydrin (TIPFENNEAU), A., i,
19.
1-Phenyl-3-ethylecyclohexadiene (BLAISE
and MAIRE), A., i, 391.
4-Phenyl-1-ethylecyclohexane-2:6-
dione and its dioxime and diphenyl-
hydrazone, and its 3:5-dicarboxylic
acid, ethyl ester and its reactions
(DIECKMANN and KRON), A., i, 388.
Phenylenylideneephosphamic chloride,
a-chloro-o-2-bromo- (STREINKOPF
and BENEDER), A., i, 963.
a-Phenylyethyly-methyl- and -ethyl-
amines, and their hydrochlorides
(BUSCH and LEFHELM), A., i,
153.
3-Phenyl-1-ethylecyclo-pentadiene and
-pentane (BORSCH and MENZ), A., i,
149.
Phenylenylopiriderinium bromide (V.
BRAUN), A., i, 678.
1-Phenyl-3-ethylpyrazoline (MAIRE), A.,
i, 291.
Phenylenylidithiobiuret (FROMM and
BAUMHAUER), A., i, 702.
Phenylenylthiuriure, action of aromatic
amines and hydrazines on (FROMM and
BAUMHAUER), A., i, 702.
Phenyfluorone and amine, N-acetyl
derivative of, and hydroxy- (KEHR-
MANN and DENGEL), A., i, 1002.
Phenyfurazan, hydroxy- (WIELAND and
SEMPER), A., i, 109.
Phenyiglycine and p-hydroxy- (HINS-
BERG), A., i, 453.
Phenylglycine, ethyl ester, preparation of (GEORGES IMBERT & CONSORTIUM FUR ELEKTROCHEMISCHE INDUSTRIE), A., i, 625.

Phenylglycine, bromo- and chloro-compounds, and their derivatives (SCHWALBE, SCHULZ, and JOCHHEIM), A., i, 974.

Phenylglycine anhydride (LEUCHS and GEIGER), A., i, 541.

Phenylglyclic acid, glacialum salt (GLASMANN and NOVICKY), A., i, 121.

8-Phenylglycylglycylglucose-α-carboxyllic acid and its lactone, and its esters (LEUCHS and LA FORGE), A., i, 724.

Phenylglyoxime, 3:4-dihydroxy-, preparation of (CHEMISCHE FABRIK AUF AKTEN VORM. E. SCHERING), A., i, 537.

Phenyl group, Tiffeneau's wandering of the (HÖRING), A., i, 497, 895.

Phenylguanido-p-tolyglycylglycine-α-carboxyllic acid, and its n- and p-nitroanilides (BONSHE and TIRING), A., i, 104.

Phenylglycollic acid, glacialum salt (GLASMANN and NOVICKY), A., i, 121.

Phenylhydrate, reactions of, with metallic cyanides and salts (STROTHERS), P., 179.

action of nitrous esters on, in alkaline solution (STOLLE), A., i, 917; (ThIELE), A., i, 927.

Phenylhydrate, nitro-derivatives, condensation of, with quinones and quinoneoximes of the benzene series (BORSCHE), A., i, 66.

p-nitro-, use of, in the identification of aliphatic aldehydes and ketones (Dakin), A., ii, 234.

2:4-dinitro-, action of hydrazine hydrate on (CURTIUS and MAYER), A., i, 53.

2-Phenylhydrazinodioethylbarbituric acid. See DIETHYLMALONYLPHENYLAMINOQUINUCLIDINE.

5-Phenylhydrazino-1-phenyltriazole, 3-thio- (FROMM and BAUMHAUER), A., i, 702.

Phenylhydrazonemesoxyalbicyclonydrazinebenzeneazoacetacetic acid, ethyl ester (BÉLOW), A., i, 254.

Phenylhydrazones, reduction of, in alkaline solution (SCHLENK), A., i, 737.

Phenylhydrotiglic acid, synthesis of (EKYMAN), A., i, 795.

Phenylimidodithiobarbituric acid. See DIETHYLMALONYLPHENYLAMINOQUINUCLIDINE.

Phenyliminoketo-See Kotonaphenylimino.

Phenyliminoquinone. See Benzquinoneanil.

Phenylindoxazan, crystallography of (JAEGGER), A., i, 985.

Phenylindoxazan, 5-nitro- (WILLGERODT and GARTNER), A., i, 877.

Phenylmalononitrile and its reactions (HESSLER), A., i, 182.

α-Phenylleucine (MERMER und SIMONS), A., i, 343.

Phenylmethanebistrinitrophenylsulphone, nitro- (FROMM und WITTMAHNN), A., i, 632.

6-Phenyl-4-p-methoxyphenyl-2-p-tolylpyridine, 3-eyano- (v. MEYER and IRMSCHER), A., i, 912.

β-Phenyl-a-methylacrylic acid, α-hydroxy-, ethyl ester (STÖRKER and FREDERICI), A., i, 181.

Phenylmeleononitrile, p-bromo- (v. BRAUN), A., i, 625, 628.

p-lodo- (v. BRAUN), A., i, 628.

Phenylmethylamcinacetonitrile, dihydroyxy- (FARBEWURKE VOM. MEISTER, LUCIUS, & BRÜNING), A., i, 418.

Phenylmethylisocyancarboline, synthesis of (SCHORIGEN), A., i, 867.
INDEX OF SUBJECTS.

1. Phenyl-6-methylbenzotriazole (Borsche, Witte, and Bothe), A., i, 367.

Phenylmethyl-n-butylallylammonium salts and p-bromo-, optical activity of (Evertatt), T., 1227; P., 143.

a-Phenyl-a-methylbutyric acid, synthesis of (Eykman), A., i, 795.

a-Phenyl-6-bromo-2-methylbenzimidazole, Phenylmethylcyanomethylethylammonium salts (Evatt), (Borsche, Freiderici), 628.

b-Phenyl-a-methylcoumarin (Stoermer and Freiderici), A., i, 181.

Phenylmethylcyanomethylethylammonium iodide (V. Braun), A., i, 628.

6-Phenyl-4-p-methylenedioxyphenyl-2-methylpyridine, 3-cyano- (v. Meyer and Irmscher), A., i, 911.

6-Phenyl-4-p-methylenedioxyphenyl-2-p-tolylylpyridine, 3-cyano- (V. Meyer and Irmscher), A., i, 912.

Phenylmethylglyoxime, 4:4-dihydroxy-, preparation of (Chemische Fabrik auf Akten vorm. E. Schering), A., i, 657.

Phenylmethylmalononitrile (Hessler), A., i, 182.

1-Phenyl-3-methyl-4-methylurethano-5-pyrazolone and its methyl carbonate and 5-pyrazolonylacetic acid, methyl ester (Farbwerke vorm. Meister, Lucius, and Brüning), A., i, 472.

3-Phenyl-1-methylcyclopentadiene (Borsche and Menz), A., i, 149.

a-Phenyl-a-methylpentane. See Hexylbenzene, active.

3-Phenyl-1-methylcyclopentane (Borsche and Menz), A., i, 149; (Gustavson), A., i, 328.

Phenylmethylpiperidinium bromide (V. Braun), A., i, 678.

1. Phenyl-5-methylpyrazole, 3-chloro- and 3-chloro-p-bromo-, and 3-chloro-m-nitro-, and their derivatives (Michaelis and Stieger), A., i, 211.

1. Phenyl-3-methylpyrazole-5-oxyacetic acid, 4-amino-, eso-anhydride of, and its N-methyl derivative (Farbwerke vorm. Meister, Lucius, & Brüning), A., i, 472.

1. Phenyl-3-methylpyrazole-5-sulphonic acid and its salts, amide, anilide, and chloride, and 4-bromo- (Michaelis and Pander), A., i, 689.

1. Phenyl-3-methylpyrazolone (Maire), A., i, 291.

1. Phenyl-3-methylpyrazolone, 5-thio-, and its derivatives (Michaelis and Pander), A., i, 689.

1. Phenyl-5-methyl-3-pyrazolone, p-bromo-, and its diazo-chloride and 4-amino-, 4-bromo-, 4-chloro-, 4-iodo-, 4-nitro-, and 4-nitroso-derivatives and their derivatives (Michaelis and Stiegel), A., i, 210.

m-nitro-, and its 4-bromo-, 4-chloro-, and 4-iodo-derivatives (Michaelis and Stiegel), A., i, 212.

1. Phenyl-3-methyl-5-pyrazolonylacetic acid, 4-amino- (Farbwerke vorm. Meister, Lucius, & Brüning), A., i, 472.

2. Phenyl-6-methyl-4-pyridone and its salts (Ruhemann), T., 1284; P., 178.

2. Phenyl-6-methyl-4-pyridone, 3-cyano- (V. Meyer and Irmscher), A., i, 911.

1. Phenyl-6-methyl-2-pyridone-3:5-dicarboxylic acid and its silver salt (Simonsen), T., 1032.

2. Phenyl-6-methyl-4-pyrone and its platinitichloride (Ruhemann), T., 433; P., 52.

3. Phenyl-1-methyl-2-quinolone (Hörner), A., i, 283.

Phenylmethyliuretet, action of aromatic amines and hydrizones on (Fromm and Baunhausser), A., i, 702.

1-Phenyl-5-methyltriazo-4-carboxylic acid (V. Meyer and Schumacher), A., i, 912.

1-Phenyl-4-methylurazole, tautomorism of salts of (Acree, Johnson, Brunel, Shadinger, and Nirdlinger), A., i, 920.

1-Phenynaphthalene, 2-o-diamino- (Bucherer and Seyde), A., i, 455.

1-Phenynaphthalene-2-a-dicarboxylic acid, constitution of (Michael and Bucher), A., i, 89; (Bucher), A., i, 791.
Phenylmethylenediamine, bases formed by condensing, with aromatic aldehydes, hydrochlorides of (Moore and Woodbridge), A., i, 686.
2- and 4-mono-, 2,4-di-, and 2,4:6-tri-nitro- and their diazo-derivatives (Morgan and Mickleton, T.), 1697.
Phenylnaphthaphenazonium, 2-hydroxy-, and its hydroxide and salts, and acetyl derivative of the hydroxide (Kehrmann and Schwarzenbach), A., i, 297.
Phenylnaphthaphenazonium, 6-hydroxy-, and its salts (Kehrmann and Brünel), A., i, 579.
2-Phenyl-β-naphthaquinoline-3:4-dicarboxylimide (Simon and Mauguin), A., i, 296.
Phenylnaphthaphenazonium, synthesis of (Fischer and Römer), A., i, 694.
Phenylnaphthaquinolines, 2- and 3-, and their α-carboxylic acids (Fischer and Schindler), A., i, 221; (Fischer and Römer), A., i, 695.
2-Phenylphenatrazine, imino-, and its additive salts (Pierron), A., i, 926.
2-Phenyl-α-naphthiminazole-8-sulphonic acid, m-amino-6-hydroxy- and m-nitro-6-hydroxy-, and 7-sulphonic acid, p-amino-9-hydroxy- (Aktien-Gesellschaft für Anilin-Fabrikation), A., i, 469.
2-Phenyl-α-naphthol and its methyl and acetyl derivatives (Decker), A., i, 806.
b-Phenyl-α-α-naphthylcarbamide, α-hydroxy- (Scheiber and Beckmann), A., i, 725.
Phenylnaphthylcarbinol and its benzoyl derivative (Pierrier and Caille), A., i, 656.
Phenylnaphthylcarbinol and its benzoyl derivative (Caille), A., i, 800.
Phenyl α-naphthyl ketone and its oxime and phenylhydrazone (Caille), A., i, 800.
Phenyl β-naphthyl ketone and its oxime, phenylhydrazone, and semicarbazone (Pierrier and Caille), A., i, 656.
Phenylnaphthylmethyl-acetyl- and -benzoyl-acetones and -benzoylacetic acid, ethyl ester (Fosse), A., i, 86.
5-Phenyl-1-β-naphthyl-3-methylpyrazole, 7'-hydroxy- (Franzen and Deibel), A., i, 832.
p-Phenyl-α-naphthylmethyltriphenylmethyl chloride (Tschitschibabin), A., i, 872.
b-Phenyl-α-α-naphthylthiocarbamide, α-hydroxy- (Scheiber and Beckmann), A., i, 725.
Phenyl-β-naphthylthiosemicarbazole, 7'-hydroxy- (Franzen and Deibel), A., i, 832.
Phenyl nitrosochlorides, trinitro-, sodium salt (Witt and Witte), A., i, 875.
Phenyl nitrosochlorides, and its hydrochloride and copper salt (Steinkopp and Benedek), A., i, 1012.
Phenylnitromethane. See Toluene, α-nitro-.
Phenylnitrosomethane. See Toluene, α-isonitro-.
Phenylnitromethane. See Toluene, α-dinitro-.
Phenyl-2:4-dinitro-1-naphthylamine (Ullmann), A., i, 627.
Phenyl-4-nitro-2-tolylidionium salts (Willebrodt and Kek), A., i, 620.
Phenyloxazolone and its condensation with aromatic aldehydes (Wahl and Meyer), A., i, 368.
1-Phenylocyclopenalene and 3-bromo- (Borsche and Menz), A., i, 149.
1-Phenylocyclopenalan and 3-carboxylic acid and its salts (Borsche and Menz), A., i, 149.
Phenylocyclopenatalene, preparation of (Borsche and Menz), A., i, 149.
1-Phenylocyclopenta-1,3-diene and its acetate and phenylethylene (Borsche and Menz), A., i, 149.
1-Phenylcyclopenta-1,3-diene and its semi-carbazone (Borsche and Menz), A., i, 149.
Phenylocyclopentene, preparation of (Borsche and Menz), A., i, 298.
Phenylophenanthrazenonium salts, hydroxy- (Ullmann and Fukut), A., i, 298.
Phenylophenazonium, 3-amino-2-hydroxy-, and its diacetyl derivative, and 2-hydroxy-, and their salts (Kehrmann and Schwarzenbach), A., i, 297.
5-Phenylophenazochionium, derivatives of (Smiles and Hilditch), T., 145, 1687; P., 199.
hydroxide and salts, α- and β-3:9-di-nitrohydroxy- (Smiles and Hilditch), T., 1692.
iso-dinitrohydroxy-, and its hydroxide and salts (Smiles and Hilditch), T., 1697.
Phenyl phenylethyl ketone, op-dihydroxy- (2'4'-dihydroxyethylalkone), and its methyl ethers and oxime (Bargellini and Marantoni), A., i, 801.

Phenylphthalazone, 3:5:6-tribromo-4-hydroxy-, and its acetyl derivative (Zincke and Buff), A., i, 645.

3-Phenylphthalazone-1-carboxylic acid, ethyl ester (Dieckmann and Meisner), A., i, 895.

Phenylphthalideanilide (Meyer), A., i, 25.

β-Phenylpipelic-δ-acetic acid and its methyl ester (Meerwein), A., i, 545.

Phenylpyridine, op-dinitro, preparation and reduction (Spiegel and Kaufmann), A., i, 293.

action of hydrazine hydrate on (Spiegel), A., i, 263.

2-Phenylpyridine and its aditive salts (Gabriel), A., i, 649.

N-Phenylperidone, 4-nitro-2-amino-, N(2)-benzoyl derivative of (Spiegel and Kaufmann), A., i, 293.

Phenylperonilidene-α-phenylenediamine (Moore and Woodbridge), A., i, 686.

γ-Phenylpropane, β-imino-α-cyano-, preparation of, and formation of 1:3-naphthylendiamine from (Best and Thorpe), P., 283.

α-Phenylpropenecyano-trimalonic acid and its esters (Meerwein), A., i, 545.

Phenylpropionic acid, alkaloidal salts, and their optical activity (Hilditch), T., 703; P., 61.

Phenylpropionic acid, bornyl and menthyl esters, optical properties of (Hilditch), T., 1.

ethyl ester, condensation of, with ketones (Ruhemann), T., 451; P., 52.

β-Phenylpropionic acid (hydrocinnamic acid), velocity of esterification of (Kailan), A., ii, 27.

β-Phenylpropionic acid, alkaloidal salts, and their optical activity (Hilditch), T., 702; P., 61.

β-Phenylpropionic acid, bornyl and menthyl esters, optical properties of (Hilditch), T., 1.

β-Phenylpropionylglycine, synthesis and degradation products of (Dakin), A., ii, 720.

α-Phenylpropylamine and its derivatives (Busch and Leeffhelm), A., i, 152.

β-Phenylpropylene β-oxide (Riedel), A., i, 967.

β-Phenyl-β-n-propylhydrcylic acid and its silver salt (Schoepfer and Buchholz), A., i, 170.

α-Phenylpropyl-methyl- and -ethylamines and their hydrochlorides (Busch and Leeffhelm), A., i, 153.

β-Phenylisopropyliminotrophenylisulphone (Fromm and Wittmann), A., i, 632.

β-Phenyl-a-iso-propylpropionic acid, β-cyano- (Avery and Upson), A., i, 343.

1-Phenyl-3-propylpyrazoline (Maire), A., i, 291.

β-Phenyl-a-iso-propylsuccinonic acid (Avery and Upson), A., i, 343.

2-Phenylpyrimidine, 5-bromo-4:6-dihydroxy-, and its acetates, and 4:6-dihydroxy- (Pinner), A., i, 1017.

4-Phenylpyrimidine, 2-cyanoamino-6-dihydroxy- (Pohl), A., i, 577.

2-Phenylpyrrolidinone and its aditive salts (Gabriel and Colman), A., i, 275.

2-Phenylpyrrolone (Gabriel and Colman), A., i, 275.

3-Phenylquinoline derivatives (Hübner), A., i, 288.

Phenyl γ-quinolyl ketone. See 4-Quinolyl phenyl ketone.

Phenylquinoxaline, synthesis of (Fischer and Römer), A., i, 694.

Phenylsalicylidene-α-phenylenediamine, hydrochlorides of (Moore and Woodbridge), A., i, 686.

Phenylsemicarbazide, conditions of formation of (Millath), A., i, 572.

α-Phenylsemicarbazide. See Phenylcarbamido, amino-

Phenyl styrly ketone, op-dihydroxy- (2':4'-dihydroxyethylalkone) (Bargellini and Marantoni), A., i, 801.

Phenyleuuscinic acid, amide acids of (Anschütz and Walter), A., i, 542.

Phenylsulphonamic acid, chloroaamino-, sodium salt (Seyewetz and Noel), A., i, 409.

β-Phenylsulphon-α-phenylpropionic acid (Posner and Baumgarth), A., i, 21.

β-Phenylsulphon-β-phenylpropionic acid and its ethyl ester, silver salt, amide, anilide, and o'-nitro-derivative (Posner and Baumgarth), A., i, 21.

β-Phenylsulphon-β-o, -m-, and γ-tolylpropionic acids (Posner and Baumgarth), A., i, 22.

2-Phenyltetrahydropyridine and its aditive salts (Gabriel), A., i, 649.

α-Phenyl-a-thienylmethylcarbinol (Thomas), A., i, 360.

Phenylthiocarbamide, reaction of, with acid chlorides (Dixon and Taylor), T., 20.

Phenylthiocarbamide, amino-, reactions of (Rolla), A., i, 473.
Phenylthiocarbimide, action of, on ethyl malonate and on ethyl cyanoacetate (Ruhemann), T., 621; P., 53.

Phenylthioglycollic-o-glyoxalic acid and its sodium salt and phenylhydrazone (Bezdzik, Friedländer, and Keininger), A., i, 201.

Phenylthioiacetic acid, preparation of (Kalle & Co.), A., i, 605.

S-Phenylthionine, hydroxy-, and its hydroxide and salts (Smiles and Hill-Ditch), T., 1696.

S-Pheny lethionine chloride and hydroxide, hydroxy-, (Smiles and Hill-Ditch), T., 1699.

Phenyl-p-tolylamine and its acetyl derivative (Goldberg and Sissoeff), A., i, 17.

Phenyl-p-tolylamine, 4-nitro- (ULLMANN), A., i, 457.

Phenyl-2'- and 4'-tolylamines, 4-amino- and 4-nitro- and their 2-sulphonic acids (Ullmann and Dahmen), A., i, 976.

6-Phenyl-2-p-tolyl-4-cinnamylpyridine, 3-cyano- (v. Meyer and Irmser), A., i, 912.

Phenyl-p-tolylidicyanodiamide (Fromm and Wellers), A., i, 701.

Phenyl-p-tolylguanidothiocarbamide and its hydrochloride (Fromm and Wellers), A., i, 701.

Phenyl-p-tolyl ketone, o-nitro- (Kliegl), A., i, 550.

Phenyl-p-tolylmethane, o-nitro- (Kliegl), A., i, 550.

4-Phenyl-6-p-tolyl-2-methylpyridine, 3-cyano- (v. Meyer and Irmser), A., i, 911.

1-Phenyltriazole, 3-(or 5)-thiol-, and its benzyl derivative (Fromm and Baumhauser), A., i, 703.

3:5-dithiol-, and its oxidation products (Fromm and Baumhauser), A., i, 703.

1-Phenyltriazolone, 5-thion- (Rolla), A., i, 474.

4-Phenyl-3:4:5-trimethoxybenzylidene-1-methyl-3-pyrazolone (Mauthner), A., i, 729.

Pheny ltrimethylammonium bromide (v. Braun), A., i, 627, 676.

γ-Phenylvaleric acid, synthesis of (Eykmann), A., i, 23.

δ-Phenylvaleric acid, β-iodo-γ-hydroxy- and γ-iodo-β-hydroxy- lactones of (Bougault), A., i, 538.

Phenylxanthylthiocarbamide (Fosse), A., i, 41.

Phenyl-m-xylilamine and its acetyl derivative (Goldberg and Sissoeff), A., i, 17.

Philothion (de Rey-Pailhade), A., i, 72.

the enzymic rôle of, towards oxygen (de Rey-Pailhade), A., i, 238.

Phloridzin diabetes. See under Diabetes.

Phloroglucide and its bromo-derivatives and their ethers and acetyl derivatives (Herzig and Kohn), A., i, 879.

Phloroglucinol, dibromo-, trimethyl ether of (v. Kostanecki and Lamie), A., i, 87.

isoPhorone. See Trimethylcyclohexene.

Phosphate minerals from Elder Rock, South Australia (Mawson and Cooke), A., ii, 397.

Phosphates. See under Phosphorus.

Phosphatides, vegetable (Winterstein and Hirstand), A., ii, 218;

(Schulze), A., ii, 977.

methods of preparation of, from plant seeds (Schulze), A., i, 385.

Phosphoprotein, reaction distinguishing nucleoprotein from (Plimmer and Scott), T., 1699; P., 200.

Phosphoproteins, distribution of, in tissues (Plimmer and Scott), T., 1699; P., 200.

Phosphorescence at low temperatures (de Kowalski), A., ii, 79.

produced by canal rays (Trowbridge), A., ii, 246.

Phosphorescent spectra. See Spectra under Photochemistry.

Phosphoric and Phosphorous acids. See under Phosphorus.

Phosphor-copper, structure of (Huntington and Desch), A., ii, 846.

Phosphor-tin, estimation of phosphorus in (Gemmel and Archbutt), A., ii, 629.

Phosphorus, the ultimate rays of (de Glanmont), A., ii, 645.

and some of its compounds, glowing of (Scharff), A., ii, 373.

ionisation by, and phosphorescence (L. and E. Bloch), A., ii, 1032.

atomic volumes of (Prideaux), P., 214.

observations on the modifications of (Stock and Johanssen), A., ii, 583.
Phosphorus, essentially chemical causes of the allotropic transformation of, dissolved in oil of turpentine (COL-SON), A., ii, 273.

colloidal, formation of (LOTTERMOER), A., ii, 1032.
gaseous, dispersion of (CUTHBERTSON and METCALFE), A., ii, 545.
Hittorf's (STOCK), A., ii, 176, 274.
crystals of (LINCK ; STOCK), A., ii, 176.
red (LINCK and MÖLLER), A., ii, 487.
formation of, from white phosphorus (COLSON), A., ii, 176.
red and yellow, non-existence of a common solvent for (COLSON), A., ii, 35.
yellow, effect of heating, in ammonia gas (LEWELLYN), A., ii, 103.
action of ammonia on (STOCK and JOHNASSEN), A., ii, 583.
influence of, on the system, iron—carbon (WÜST), A., ii, 287.
in certain foods (HEUBNER and REEB), A., ii, 1052.
in the fat of micro-organisms (ALLAIRE), A., ii, 123.
action of, on the circulation of calcium in normal and rachitic children (FLAMINI), A., ii, 406.
metabolism. See under Metabolism.
poisoning by. See Poisoning.

Phosphorus alloys with carbon and iron (GOERENS and DODEBESEN), A., ii, 1042.
with copper. See Phosphor-copper.
with iron (GERCKE), A., ii, 1041.
with tin. See Phosphor-tin.

Phosphorus compounds with nickel (KONSTANTINOFF), A., ii, 855.
with silicon, titanium, and zirconium (GEWECKE), A., ii, 597.

Phosphorus amino-compound in egg-yolk (MACLEAN), A., ii, 963.

Phosphorus pentabromide, liquid, specific volumes of (PRIDEAUX), P., 214.
chloride and gold chloride, complex, derivatives of (LEVY-MALVANO), A., i, 774.
pentachloride, chlorinating action of (HORNING and BAUM), A., i, 527 ; (SCHMIDT), A., i, 654.
action of, on halogenated acid amides (STENKOFF, BENEDIK, GEÜNUPF, and KIRCHHOFF), A., i, 961.
action of, on the methylene ethers of catechol derivatives (BARGER), T., 593, 2081 ; P., 50, 237.
reaction of, with phenols (AUTENRTH and GEYER), A., i, 166.
action of, on phenolsulphonic acids (ANSCÜTZ), A., i, 83.

Phosphorus, chloronitride, action of ammonia on (BESSON and ROSSET), A., ii, 583.
ydride. See Hydrogen phosphide.

pentoxide (phosphoric oxide), estimation of, by uranium (REPTON), A., ii, 320, 428.

Phosphoric acid, electrical conductivity of (PHILLIPS), P., 239.
quantitative vapourisation of, from phosphates in a current of chlorine and carbon tetrachloride or of carbon tetrachloride only (JAN-NASCH and JILKE), A., ii, 685.
action of, on silicic acid and silicate glass (HÜTTLER), A., ii, 838.
reversion of, in superphosphates (HERST), A., ii, 374.
in barley (WINDISCH), A., ii, 528.
loss of, in the incineration of cereals (LEAVITT and LE CRECO), A., ii, 428, 531.
in soil. See under Soil.
esterification of, by glycerol (PRU-NIER), A., i, 2.
esters, preparation of, from phosphoric oxide and the diglycerides of fatty acids, and their bromo- and iodo-derivatives (ULZER and BATIK), A., i, 599.
hematoxylin as an indicator in the titration of (LYONS), A., ii, 532.
titration of, in superphosphates (KOHN), A., ii, 531, 895.
detection of, in minerals (LIDOFF), A., ii, 894.
estimation of (V. LORENZ), A., ii, 777 ; (FALLADA), A., ii, 933.
estimation of, volumetrically (COB- LENTZ and MAY), A., ii, 428.
estimation of, alkaliometrically, by Neumann's method (GREGersen), A., ii, 64.
Pemberton's method for the estimation of (LAGERS), A., ii, 896.
estimation of, as phosphomolybdic acid (CHRISTENSEN), A., ii, 895 ; (HABEN), A., ii, 896.
estimation of, by the uranium process (REPTON), A., ii, 320, 428.
estimation of, in basic slags by GreTe's method (KETNER), A., ii, 64.
estimation of, in urine (FERRARO), A., ii, 733.
Phosphorus:

Phosphoric acid, alumina, and iron, estimation of, in presence of each other (Cooksey), A., ii, 987.
separation of, from tungstic acid (v. Knothe), A., ii, 231.

Phosphates, acid (Parravano and Mielj), A., ii, 837.
insoluble, of raw bone-meal and natural raw rock phosphate, solvent action of soil bacteria on (Sackett, Patten, and Brown), A., ii, 415.
sparingly soluble, factors which influence the manurial action of (Söderbaum), A., ii, 728.
and other salts soluble in acids, qualitative analysis of (Caron and Raquet), A., ii, 630.
See also Mineral phosphates.

Polyphosphates (Parravano and Calcagni), A., ii, 838.

Phosphoric acids, molecular weights of, determined by cryoscopy (Giran), A., ii, 686.
hydrates of (Giran), A., ii, 685.

Hypophosphoric acid, molecular weight and hydrates of (Rosenheim and Pritze), A., ii, 942.

Phosphorous acid, constitution of (Palazzo and Maggiacomo), A., ii, 488.
oxidation of, by iodine (Steele), T., 2203; P., 198.

Hypophosphorous acid, effect of temperature on the maximum electrolytic conductivity of (Wegelius), A., ii, 801.

Superphosphate, action of, on mangolds (Sjöllema and van Daalen), A., ii, 618.

Superphosphates, titration of phosphoric acid in (Kohn), A., ii, 531, 895.

Phosphorus trithodanide (Dixon and Taylor), T., 2153; P., 239.
sulphides, vapour densities of (Stock and v. Bezold), A., ii, 274.
pentasulphide (Stock and Scharfenberg), A., ii, 274.

Phosphoryl bromide (Berger), A., ii, 274.
trithodanide (Dixon and Taylor), T., 2157; P., 239.

Phosphorus organic compounds, absorption and assimilation of (Marfori), A., ii, 1052.
with gold (Levi-Malvano), A., i, 775.
with nitrogen and sulphur in vegetables (Stutzer), A., ii, 124.

Phosphorus, antimony, and arsenic, microchemical detection of traces of (Sjöllema), A., ii, 224.
the nitro-molybdate method for the detection of, in tissues (Nasmith and Fidalgar), A., ii, 776.
estimation of, in ash analysis (Leavitt and Le Clerc), A., ii, 428, 531.
estimation of, in calcium carbides (Hinrichsen), A., ii, 131.
estimation of, in cast-iron, iron, and steel (Cheneau), A., ii, 427.
new method of estimating, in organic compounds (Bay), A., ii, 531.
estimation of, in phosphor-tin (Gemmell and Archbutt), A., ii, 629.

Phosphorus arsonic group, allotropic modifications of the elements of the (Linck), A., ii, 176, 373; (Erdmann), A., ii, 275.

Phosphoryl compounds. See under Phosphorus.

Photochemistry:

Photochemistry (Trautz), A., ii, 339.

Light, chemical action of (Ciamici and Silber), A., i, 277, 555;
(Weigert), A., ii, 5, 914;
(Ciamiciani; Fowler), A., ii, 914.
electrochemistry of (Bancroft), A., ii, 448, 549, 788.
a theory of the catalytic influence of (Weigert), A., ii, 5.
action of, on water of crystallisation (McKee and Berkheiser), A., ii, 1003.
absorption of, in solutions of aniline colours from the standpoint of optical resonance (Kalandek), A., ii, 139.
ultra-violet, reactions in (Thiele), A., ii, 79.

Sunlight, catalytic reactions of (Neuberg), A., ii, 915.
action of, on the glass of old mirrors (Maschhaupt), A., ii, 1003.
tropical, chemical action of (Fowler), A., ii, 914.

Photochemical cyclic action (Luther and Plotnikoff), A., ii, 140.
equilibria and catalytic reactions (Vanzetti), A., ii, 915.
processes, thermodynamic treatment of (Weigert), A., ii, 748.
pseudo-reversible (Luther and Plotnikoff), A., ii, 140.
reactions (Weigert), A., ii, 5, 914.
INDEX OF SUBJECTS.

PHOTOCHEMISTRY:—

Photochemical reactions, the mathematical treatment of, on thermo-dynamical and electrochemical basis (Byrk), A., ii, 339.

Photo-electric sensitiveness and fluorescence of organic substances (Stark and Strehbing), A., ii, 746.

Photographic action of metals and hydrogen peroxide (Sæland), A., ii, 789.

films, the silver hydrogel in (Lüppo-Cramer), A., ii, 841, 945, 1024.

image, reduction of, with persulphate and according to Farmer (Pinnow), A., ii, 245.

latent, as a colloidal compound (Lüppo-Cramer), A., ii, 378.

impressions produced by radium emanations (Muñoz del Castillo and Díaz de Rada), A., ii, 749.

plates, action of potassium salts on (Levin and Ruer), A., ii, 448.

preparations, relation of absorption and sensitiveness in (Lehmann), A., ii, 789.

Optical activity and unsaturation, relation between (Hilditch), T., 1, 700, 1388, 1618; P., 61, 186, 195.

of compounds having simple molecular structure (Pope and Read), T., 794; P., 99.

of nitrogen compounds, effect of constitution on the (Everatt), T., 1225; P., 148.

antipodes, physiological action of, on higher organisms (Bruni), A., ii, 876.

electric properties of liquid mixtures (Chaudier), A., ii, 788.

inversion, Walden's (McKenzie and Clough), T., 811; P., 91; (Fischer and Scheibler), A., i, 324, 857.

isomerides (v. Östromisslensky), A., ii, 913.

physiological action of (Cushny), A., ii, 720.

magneto phenomena, use of very low temperatures for the study of (Becquerel), A., ii, 3.

properties and electron theory (Erfle), A., ii, 77.

properties of liquids, application of, to the study of polymerisation and analogous phenomena (Andréff), A., ii, 547.

of dissolved substances, influence of temperature on the (Chéneveau), A. ii, 77.

PHOTOCHEMISTRY:—

Optical rotatory power, determination of (Caldwell and Whymper), A., ii, 817.

Optically active compounds, relation between rotatory power and chemical constitution of (Chardin and Sikorsky), A., ii, 470; (Chardin), A., ii, 548, 912.

influence of solvents on the rotation of (Patterson and Thomson), T., 355; (Patterson and MacDonald), T., 936; P., 125; (Patterson), T., 1836; P., 216.

See also Nitrogen compounds.

Optically isomeric substances, relative rate of absorption of, from the intestine (Dakin), A., ii, 710.

Radiation from drying oils (Schmidt), A., ii, 796.

from radioactive substances, distribution of the (Greinacher), A., ii, 551; (Schmidt), A., ii, 791.

metallic, so-called (Sæland), A., ii, 789.

penetrating, so-called (Sæland), A., ii, 789.

of the Heffner lamp and of osmium (Leder), A., ii, 5.

Radiations, invisible, from the explosive discharge in air (Schincaglia), A., ii, 796.

Rays, chemical changes produced by different kinds of (Neuberg), A., ii, 915.

positive, nature of the (Wien), A., ii, 1006.

ultimate, of the metalloids (de Gramont), A., ii, 645.

ultra-violet, detection of (Schall), A., ii, 139.

α-Rays, range of activity and absorption of (Aschkinass), A., ii, 920.

ionisation due to (Moulin), A., ii, 921.

retardation of, by metal foils, and its variation with the speed of the α-particles (Taylor), A., ii, 793.

α-Particle, charge and nature of the (Rutherford and Geiger), A., ii, 794.

α-Particles from radioactive matter, method of counting the number of (Rutherford and Geiger), A., ii, 555.

β-Rays, quality of the secondary ionisation due to (Bragg and Madsen), A., ii, 921.

of radioactive elements, absorption of (Hahn and Meitner), A., ii, 452.
Photochemistry:

β-Rays from uranium, scattering of, by matter (Crowther), A., ii, 247.

secondary (McClelland), A., ii, 650.

Rays, α, β, and secondary, from radioactive substances, changes in velocity in an electric field of (Eve), A., ii, 555.

γ-Rays, nature of the (Thomson), A., ii, 751.

experimental investigation of the nature of (Bragg and Madsen), A., ii, 556.

secondary, due to γ-rays of radium C (Eve), A., ii, 795.

Anode rays (Gehrcke and Reichenheim), A., ii, 343.

Canal rays, distribution of intensity in the spectra of, in hydrogen (Stark and Steubing), A., ii, 546.

Doppler effect with, in the spectra of oxygen (Stark), A., ii, 545.

phosphorescence produced by (Trowbridge), A., ii, 246.

volatilisation produced by (Stark), A., ii, 1007.

Cathode rays, secondary, from gases, velocity of (Thomson), A., ii 751.

Moser rays, so-called (Legrády), A., ii, 142.

Röntgen rays, heat effects produced by, in lead and zinc (Bumstead), A., ii, 342.

action of, on corundum (Bordas), A., ii, 9.

have, an action on radioactive substances? (Guye, Schidlof, and Kernbaum), A., ii, 142.

influence of pressure on ionisation produced in gases by (Rothé), A., ii, 1007.

Radioactive changes, influence of temperature on (Engler), A., ii, 650.

Radioactive compounds, kinetics of the transformations of (Guye), A., ii, 451.

Radioactive emanations, condensation of (Henriot), A., ii, 651.

in air, amount of, from the soil (Gockel), A., ii, 452.

absorption of, by charcoal (Boyle), A., ii, 1005.

Radioactive minerals, association of helium and thorium in (Strutt), A., ii, 144.

the lithium in (Gleditsch), A., ii, 9, 246; (Ramsay and Cameron), A., ii, 247.

Radioactive substances, distribution of the radiation from (Greinacher), A., ii, 551; (Schmidt), A., ii, 791.

have X-rays an action on? (Guye, Schidlof, and Kernbaum), A., ii, 142.

See also Actinium, Actinium C, Alkali metals, Ionium, Meso-thorium, Polonium, Potassium, Radio-lead, Radiothorium, Radium, Thorium, Uranium, Uranium compounds, and Uranyl molybdate.

Radioactivity, lectures on (Marckwald; Debierre), A., ii, 550.

law of transformation in stages and (Schmidt), A., ii, 550.

and helium in rare and common minerals (Strutt), A., ii, 649.

in Australian minerals (Mawson and Laby), A., ii, 917.

atmospheric, constituents of (Dadourian), A., ii, 453.

excited, rate of decay of, from the atmosphere of Sydney (Lusby and Ewing), A., ii, 916.

of air over the open sea (Runge), A., ii, 80.

of ordinary metals and the penetrating radiation from the earth (McLennan), A., ii, 648.

of Roumanian petroleums (Hurmuzescu), A., ii, 453.

of the rocks in the region traversed by the line to the Simplon (Gallo), A., ii, 917.

of sea water (Joly), A., ii, 246.

of springs. See under Water.

of uranium minerals (Boltwood), A., ii, 454.

of Vesuvian cotunnite (Rossi), A., ii, 9.

Radiology, reflections on (Reychler), A., ii, 1003.

Polarimetric measurements with small quantities of liquid (Donau), A., ii, 647.

study of intramolecular rearrangement in inactive substances (Patterson and McMillan), T., 1041; P., 135.

Dispersion and refraction of triazocompounds (Philip), T., 918; P., 114.

abnormal, of metallic vapours (Schön), A., ii, 334.

Refraction and dispersion of triazo-compounds (Philip), T., 918; P., 114.
Photochemistry:

Molecular refractions of some carbamidoximes (Conduché), A., i, 156.

Refractive index of mixtures of alcohols and water (Doroschewsky and Dworschantschik), A., ii, 241, 755.

of alcohol and water mixtures (Doroschewsky and Dworschantschik), A., ii, 241; (Andrews), A., ii, 333.

of solutions (Getman and Wilson), A., ii, 1001.

Refractive power of diphenylhexatriene and allied hydrocarbons (Smedley), T., 372.

Refractometric researches (Eykman), A., ii, 1.

Refractometric studies of some methane derivatives in which two or three atoms of hydrogen are replaced by negative radicles (Haller and Muller), A., ii, 445, 1001.

Magnetic double refraction of organic liquids (Cotton, Mouton, and Weiss), A., ii, 2.

Magnetic rotation of the plane of polarisation, anomalous, of the rare earths (Elis), A., ii, 549.

Rotation of the plane of polarisation, natural and magnetic, in crystals (Voigt and Honda), A., ii, 912.

Rotation, influence of temperature change on, in solution (Patterson), T., 1836; P., 216.

of optically active compounds, influence of solvents on (Patterson and Thomson), T., 355; (Patterson and McDonald), T., 936; P., 125; (Patterson), T., 1836; P., 216.

Rotatory dispersion, anomalous, a case of (Dahmois), A., ii, 747.

Rotatory polarisation in crystals which are not enantiomorphs (Sommerfeld), A., ii, 339.

Rotatory power and chemical constitution, relation between (Chardin and Sikorsky), A., ii, 470; (Chardin), A., ii, 548, 912.

the relative influence of bi, quadri, and sexa-valent sulphur on (Hilditch), T., 1618; P., 195.

in solutions (Patterson), A., ii, 77.

of amines of camphorcarboxylic acid (Minquin), A., ii, 157.

of optically active ammonium compounds, effect of constitution on the (Jones and Hill), T., 295; P., 28.

Photochemistry:

Rotatory power of optically active nitrogen compounds, effect of constitution on the (Everatt and Jones), T., 1759; P., 212.

of organic substances (Dewar and Jones), A., ii, 258.

Magnetic rotatory power, dispersion of, in the neighbourhood of bands of absorption in rare earths (Bequerel), A., ii, 647.

Spectra, wave-length tables of the, of elements and compounds (British Association Reports), A., ii, 334.

regularities in the structure of (Stahl), A., ii, 445.

of the discharge from a glowing lime cathode in mercury vapour (Horton), A., ii, 745.

of the alkali metals (Rungel), A., ii, 78; (Ritz), A., ii, 445.

of the alkali metals, the absolute distribution of intensity in the continuous background of the (Leder), A., ii, 5.

of some compound gases (Gehlhoff), A., ii, 11.

of non-dissociated compounds (Bequerel), A., ii, 139.

absorption, and chemical constitution, relation between (Baly and Desch), T., 1747; P., 173; (Baly and Schaefler), T., 1808; P., 207; (Baly and Tuck), T., 1902; P., 223; (Baly and Marsden), T., 2103; P., 235; discussion, P., 236; (Baly, Collie, and Watson), P., 268.

influence of temperature and magnetisation on selective (Du Bois and Elias), A., ii, 337, 547.

influence of temperature changes on the, of solid substances (Bequerel), A., ii, 78.

of the vapours of benzene and its homologues at different temperatures and pressures, and also of solutions of benzene (Hartley), A., ii, 243.

of crystals of the rare earths and the changes which they undergo in a magnetic field at the temperatures of liquefaction and solidification of hydrogen (Bequerel and Onnes), A., ii, 338.

of molten salts, influence of temperature and of the state of aggregation on (Retschinsky), A., ii, 910.
Photochemistry:

Spectra, arc, presence of spark lines in (Fabry and Buisson), A., ii, 334.

banded, energetics and chemistry of (Stark), A., ii, 138, 545, 574.

anomalous modifications of the, of different compounds in the magnetic field (Dupouy), A., ii, 138.

fluorescence in (Stark and Stebbing; Ley and V. Engelhardt), A., ii, 911.

discontinuous cathode luminescence, of some aromatic compounds (Fischer), A., ii, 909.

dissociation, quantitative indications furnished by (de Gramont), A., ii, 787.

emission, cause of, of the principal series lines of the alkali metals and the Doppler effect in canal- and anode-rays (Fredenhagen), A., ii, 79.

ultra-red emission, of the alkali metals (Bergmann), A., ii, 242, 336.

some infra-red (Moll), A., ii, 241.

infra-red reflection (Coblentz), A., ii, 338.

phosphorescent (Bequerel), A., ii, 243.

series, new law of (Ritz), A., ii, 736.

spark, of solutions, apparatus for the production of (de Gramont), A., ii, 3.

Spectrum, the Swan (v. Wesendonk), A., ii, 241.

Zeeman phenomenon (Lohmann), A., ii, 152.

Spectral lines of barium, osmium, yttrium, and zirconium in a magnetic field, resolution of the (Moore), A., ii, 138.

Spectral series and atomic decomposition (Bernoulli), A., ii, 1001.

Spectroscopic apparatus, modified (Baxter), A., ii, 337.

Spectroscopic behaviour of hydrocarbons with conjugate ethylene linkings (Bruhl), A., ii, 1002.

Spectroscopical investigation of isomeric nitro-compounds in the ultraviolet (Hedley), A., i, 382.

Spectrophotometer, König, new arrangement of the, and its application to the determination of chemical equilibria (Hildebrand), A., ii, 646.

Spectrum analysis, use of very low temperatures for (Bequerel), A., ii, 3.

Photographic action, films, images, plates, and preparations. See under Photochemistry.

Photométhaeoglobin (Leers), A., i, 843.

"Photo salts," Carey Lea's, simplest method of preparing (Lüppo-Cramer), A., ii, 691.

Phototropy of the fulgides and other substances (Stobbe), A., ii, 339.

Pthalacene and its oxide, structure of (Errera), A., i, 183.

Pthalacenic acid, structure of (Errera), A., i, 184.

Pthalacone (Errera), A., i, 184.

o-Pthalaldehyde, action of Grignard's compounds on (Nelken and Simonis), A., i, 348.

Pthalaldehydo-acid, tribromo-4-hydroxy-, and its methyl esters and methyl ether, and their acetyl derivatives, and anilide (Zincke and Buff), A., i, 644.

Pthalamic-p-iodobenzylacetic acid (Wheeler and Clapp), A., i, 981.

Pthalamin-, See under the parent Substance.

Pthalalani, 4-amino- (Bogert and Renshaw), A., i, 652.

3:5:6-tribromo-4-hydroxy-, and its salts and acetyl derivative (Zincke and Buff), A., i, 645.

Pthalalanic acid, tribromo-4-hydroxy- (Zincke and Buff), A., i, 645.

Pthalelins and their salts, reactions of (Acree), A., i, 423; (Acree and Slagle), A., i, 653.

salts, constitution of (Meyer and Marx), A., i, 652.

constitution of the salts of, and the cause of the colour in the triphenylmethylene series (Green), P., 206.

of mellitie and pyromellitic acids, constitution of the (Silberbadian), P., 209.

Pthalic acid, nitrations of (Huisinga), A., i, 985.

Pthalic acid, glucinium salt (Tanatar and Kurovska), A., i, 758.

Pthalic acid, 4-amino-, and its salts, and the carbamide and acyl derivatives of the methyl ester (Bogert and Renshaw), A., i, 652.

3:5:6-tribromo-4-hydroxy-, and its methyl hydrogen ester and dimethyl ester, and its acetyl derivative (Zincke and Buff), A., i, 646.

3-nitro-, formation of methyl esters of (Wegscheider), A., i, 793.

Phthalic acid, nitration of (Huisinga), A., i, 985.
Phthalic anhydride, action of, on res-acetophenone (Torrey and Brewster), A., i, 427.

Phthalic anhydride, 4-amino-, and its N-acetyl derivative (Bogert and Renshaw), A., i, 652.

Phthalic anhydride, 3:5:6-tri-bromo-4-hydroxy-, and its salts, acetyl derivative, and phenyl-hydrzone (Zincke and Buff), A., i, 645.

isoPhthalic anhydride (Bucher), A., i, 792.

Phthalide, bromo-4-hydroxy-derivatives, and their acetyl derivatives (Zincke and Buff), A., i, 644.

Phthalides (Mermod and Simonis), A., i, 342.

Phthalidecarboxylic acid and its silver salt, formation of (Creeth and Thorpe), T., 1512; P., 193.

2-Phthalide-5-methoxyphenoxyacetic acid, preparation of (Perkin and Robinson), T., 511.

Phthalimide, 4-amino-, and its hydrochloride (Bogert and Renshaw), A., i, 652.

Phthalimino-3:5:6-tri-bromobenzylmalonic acid, ethyl ester (Wheeler and Clapp), A., i, 898.

γ-Phthaliminobutyric acid and its derivatives (Gabriel and Colman), A., i, 274.

γ-Phthaliminobutyrophenone (Gabriel and Colman), A., i, 275.

e-Phthalimino-hexoic acid and its chloride and -hexophenone (Gabriel and Colman), A., i, 649.

Phthalimino-β-hydroxyethylmalonic acid, lactone of, ethyl ester (Sorensen and Andersen), A., i, 650.

Phthalimino-β-iodobenzylmalonic acid, ethyl ester (Wheeler and Clapp), A., i, 981.

4-Phthalimino-2-phthalic acid, methyl ester (Bogert and Renshaw), A., i, 652.

Phthaliminopropiophenones, α- and β- (Gabriel), A., i, 181.

3-Phthalimino-valeric acid and its chloride and -valerophenone (Gabriel), A., i, 649.

Phthalimethylide, 4-amino- and 4-nitro- (Bogert and Renshaw), A., i, 652.

Phthalonic acid, esterification of (Weischeider), A., i, 793.

Phthalonic anhydride phenylhydrzone (Dieckmann and Meiser), A., i, 894.

4-Phthaloyl-3-methoxyphenoxyacetic acid (Perkin and Robinson), T., 512.

β-Phthalylalanine, α-bromo-, and its esters, and α-thiocyanato- ethyl ester (Gabriel), A., i, 181.

Phthalylalanyl chlorides (Gabriel), A., i, 181.

Phylloporphyrin, simple method of preparing (Marchlewski and Pia-secki), A., i, 357.

Phyllotoxin, conversion of, into phytoshodius (KozineWSki and Marchlewski), A., i, 668.

Phyllloxanthin (Marchlewski), A., i, 652; (Tvett), A., i, 668.

Physical constants for non-associated liquids, new formulae correlating the (Higgins), A., ii, 668.

Physiological action and chemical constitution, relation between, in certain substituted aminoalkyl esters (Pyman), T., 1793; P., 208.

of optical isomerides (Cushny), A., ii, 720.

of substances of the saponin group (Wacker), A., ii, 771.

Physiological actions, temperature velocities of (Snyder), A., ii, 763.

Physiological catalysis (Loew), A., ii, 710.

Physiological fluids, analysis of the lowering of the freezing point in (Tezner), A., ii, 16; (Tezner and Roska), A., ii, 810.

Physostigmine. See Eserine.

Phytase in animal tissues (McCollum and Hart), A., ii, 713.

which decomposes anhydro-oxy methyl-enediphosphoric acid (Suzuki, Yoshimura, and Takaishi), A., i, 235.

Phytelephas, carbohydrates of (Ivandoff), A., ii, 1064.

Phytin in barley (Windisch), A., ii, 528.

occurrence of, in plants (Suzuki and Yoshimura), A., ii, 124.

constitution of (Neuberg), A., i, 394.

constitution of, and production of inositol from (Suzuki, Yoshimura, and Takaishi), A., i, 236.

Phytohaematin (Falladin), A., ii, 417.

Phytorhodina, formation of, from phytolactonic (KozineWSki and Marchlewski), A., i, 663.

Phytosterol, C_{27}H_{44}O\_2, and its acetyl derivative and dibromide, from laurel oil (Matthews and Sander), A., i, 418.

Phytosterol from cotton-seed oil, and its dibromo-derivative and dibromo-acetate (Heibuschka and Gloth), A., i, 883.
Phytosterol, double linkings in, and its ozonide (Molinari and Fenaroli), A., i, 882.

Phytosterols from balata (Cohen), A., i, 883.
from South African “rubber” (Cohen), A., i, 884.

Phytosteryl acetate, tetrambromo- (Matthews and Ackermann), A., i, 638.

Picene, alkyl derivative of (Homer and Purvis), T., 1325; P., 147.

α-Picoline (2-methylpyridine), chlorination of (Sell), T., 1993; P., 225.

α-Picoline, 6-hydroxy- (Simonsen), T., 1031.

γ-Picoline, condensation of, with o-nitrobenzaldehyde (Löwensohn), A., i, 51.

Picolinecarboxylic acid, isolation of, from soils, and its relation to soil fertility (Schreiner and Shorey), A., ii, 889.

Picolinic acid, 3-amino- and 3-hydroxy- (Kirpal), A., i, 565.
3,5-dichloro-, and its methyl ester and amide (Sell), T., 1995; P., 225.

Pieramide acetate, α- and β-naphthylamines, and α- and β-naphthols (Witt and Witte), A., i, 874.

Pierates (Suida), A., i, 523; (Anselmino), A., i, 879.

Pieric acid solutions, conductivity of (Gorke), A., ii, 150.
heat of neutralisation of, by different aromatic bases in benzene solution (Vignon and Évieux), A., ii, 664.
oxidation by means of (Bacovescu), A., i, 826.
molecular compounds of (Gibson), T., 2098; P., 241.
evaluation of (Utz), A., ii, 233.
estimation of (Busch and Blume), A., ii, 328.

Pieric acid, metallic salts, and their hydrates and hydrizine salt (Silberd and Phillips), T., 474; P., 22.
ammonium salt, isomeric modifications of (Anselmino), A., i, 879.

Pierolonates (Wheeler and Jamieson), A., i, 255.

Pieryl compounds, fluorescence phenomena in (Leemann and Grandmougin), A., i, 478.

Pieryl-α-toluidine (Leemann and Grandmougin), A., i, 480.

Pieryl-35e-triphenylguanilamide (Levy, Müller, and Krafft), A., i, 571.

Pigment of yellow autumn leaves (Tsvelet), A., i, 279.
secretion of Aplysia punctata, spectroscopic and chemical behaviour of (Paladino), A., ii, 53.

Pigments, decoloration of, in the visible spectrum (Lazaroff), A., ii, 4.
colloid nature of, in relation to their behaviour in the frog’s kidney (Höber and Chassin), A., ii, 875.
excretion of, by the urine (Höber and Kempner), A., ii, 716.
respiratory, of plants (Palladin), A., ii, 416.
urinary. See Urinary pigments.

Pilolite from the Pyrenees (Friedel), A., ii, 400.

Pimelic acid, electrolytic decomposition of (Vanzetta), A., i, 939.

Pimelic acid, α-diamino-, synthesis of, and its dibenzoyl derivative (Sörensen and Andersen), A., i, 651.

Pimpinellin (Hierzog and Hancu), A., i, 905.

Pinacolin (methyl tert.-butyl ketone), solubility and reactions of (Delange), A., i, 762.
relation of tetramethylethylene to (Delacre), A., i, 243.

Pinacone, C10H18O2, from 1-phenyl-1-cyclopenten-3-one (Bosche and Menz), A., i, 148.

Pinacone hydrogen peroxide (Tanatar), A., i, 400.

Pine tar oil, Russian (Schindelmieiser), A., i, 95.

Pine-wood, chemical composition of (Klason; Klason and Fagerlind), A., i, 717.

Pinene, hydration of (Babier and Grignon), A., i, 94.
action of ozone on (Harries and Neresheimer), A., i, 194.
oxidation products of (Henderson and Heilbron), T., 288; P., 31.

d-Pinene, hydration of (Smirnoff), A., i, 278.

l-Pinene chloroxime, action of piperidine on (Golubeff), A., i, 902.
β-Pinene (naphene), synthesis of, from nopinone (Wallach), A., i, 997.

Pinenericarboxylic acid, amino-, condensation of, with aspartic acid and with glycine (Godden), T., 1117; P., 144.

Pinic acids, active (Babier and Grignon), A., i, 852.
Pinocamphene xanthate (Tschugaeff), A., i, 93.

l-Pinocamphene dibromide (Schimmel & Co.), A., i, 667.

l-Pinonic acid (Schimmel & Co.), A., i, 667.

Pinonic acids, active, and their oximes (Barbier and Grignard), A., i, 852.

Pinus Jeffreyi, resin of (Tscharc and Leuchtenberger), A., i, 196.

Pinus palustris, oil from. See Long leaf pine oil.

Pineus serotina, volatile oil of (Herty and Dickson), A., i, 435.

4-Piperidine-3-carboxylic acids. See Cincholeanuonic acids.

Piperazine derivatives and pyrrole derivatives, synthesis of, from the three nitroanilines (Borsche and Tittingh), A., i, 103.

Piperidine, 4-chloro-3-cyano-, hydrochloride of, and 3-cyano-, reactions of (Wohl and Losantisch), A., i, 47.

Piperidine-3-aldehyde and its additive salts and diethylacetal and 4-chloro-, diethylacetal of, and its 1-benzoyl derivative, and dimethylacetal of (Wohl and Losantisch), A., i, 46.

Piperidines, mutual solubility of, and water (Flaschner), A., ii, 364.

tertiary, formation of (v. Braun), A., i, 677.

Piperidino. See Piperidyl.

4-Piperidylacetic acid, a-3-cyano-, and its hydrochloride (Wohl and Losantisch), A., i, 48.

γ-Piperidylacetoacetic acid, ethyl ester, and its salts (Benary), A., i, 601.

Piperidylacetophenone and its methiodide and their benzoyl derivatives (Rabe, Schneider, and Braasch), A., i, 361.

Piperidylethyl benzoate and its additive salts and physiological action (Pyman), T., 1795; P., 208.

Phthalate and its additive salts (Pyman), T., 1805; P., 208.

Salicylate and its hydrochloride (Farnwerke vorm. Meister, Lucius, & Brüning), A., i, 176.

Piperidymethylmandelamide (Einhorn), A., i, 611.

Piperil, action of thionyl chloride on (Barger and Ewins), T., 735; P., 60.

Piper methysticum (Kawa root) (Winzheimer), A., i, 804.

Piperonal, condensation of, with benzidine, p-bromoanilino, m-nitroanilino, and p-phenylenediamine (Moore and Gale), A., i, 369.

action of phosphorus pentachloride and of thionyl chloride on (Barger), T., 572.

Piperonasynoxime, rate of inversion of, in inactive substances (Patterson and McMillan), T., 1043; P., 135.

Piperonyl alcohol, action of thionyl chloride on (Barger), T., 567.

Piperonylacetone and its semicarbazone (Behal and Tiffeneau), A., i, 631.

Piperonylaldehyde derivatives, preparation of (Winzheimer), A., i, 656.

Piperonylacyric acid. See Methylendioxybenzoylacrylic acid.

γ-Piperonylisocrototic acid, α-hydroxy- (Bougault), A., i, 539.

Piperonylenecetone, identity of, with methylsticol, and its derivatives (Winzheimer), A., i, 656.

Piperonylidene-paminobenzoic acid, ethyl ester, p-chloroanilino, and p-toluidine and their monohydrochlorides (Moore and Gale), A., i, 369.

Piperonylidene-p-aminodimethylanilino and its hydrochlorides (Moore and Gale), A., i, 369.

Piperonylidene-carbamidoxime (Conduché), A., i, 154.

Piperonylideneaminylidenecetone and its hydrochloride and bromides (Francesconi and Cusmano), A., i, 802.

Piperonylidinemethylsticol (Winzheimer), A., i, 805.

Piperonylideneopyruvic acid, iodo-lactone from (Bougault), A., i, 539.

Piperonyloin, action of thionyl chloride on (Barger and Ewins), T., 735; P., 60.

Pipette, improved (Woithe), A., ii, 827.

automatic syphon (Bailey), A., ii, 827.

and measuring vessel, rapid (Schubert), A., ii, 424.

and wash-bottle, combined (Hogarth), A., ii, 981.

Pisium sativum. See Pea.

Pitchblende, preparation of radium from (Pawlick), A., ii, 917.

Pitchblende residue, treatment of (Hattinger and Ulrich), A., ii, 857.
Pituitary body, chemistry of the infundibular portion of the (ALDRICH), A., ii, 313.
extract, duration of effect of, on blood pressure (MUMMERY and SYMES), A., ii, 767.
Placenta, nucleo-protein of the (SAVARÉ), A., i, 69.
Plancheite from the French Congo (LACROIX), A., ii, 508.
Plant extracts containing chlorophyll, photodynamic action of (HAUSMANN), A., ii, 881.
metabolism, toxic substances arising during (SCHREINER and SULLIVAN), A., ii, 422.
nutrition, importance of the fixation of nitrogen in soil by free bacteria for (KOCHEI, LITZENDORFF, KRULL, and ALVES), A., ii, 56.
roots, toxic substance excreted by (FLETCHER), A., ii, 617.
Plants, origin of the colouring matter of (LABORDE), A., ii, 774.
mechanism of the distribution of odoriferous principles in (CHARABOT and LALOUE), A., ii, 774.
effect of carbon disulphide on (EGOROW), A., ii, 421.
influence of didymium and glucinium on (KANOMATA), A., ii, 616.
effects of variations in inorganic salts and reaction on (MOORE, ROAF, and KNOWLES), A., ii, 768.
absorption of varying amounts of lime and magnesia by (TAKEUCHI), A., ii, 624.
behaviour of certain organic substances in (CIAMICIAN and RAVENNA), A., ii, 773.
influence of micro-organisms on the utilisation of the potassium in leucite by (DE GRAZIA and CAMIOLA), A., ii, 415.
in both water and sand cultures, effect of the addition of sodium to deficient amounts of potassium on the growth of (HARTWELL, WHEELER, and PEMBER), A., ii, 428.
action of sulphur dioxide on (WIENER), A., ii, 887.
growing in solution cultures, power of sodium nitrate and calcium carbonate to decrease toxicity in conjunction with (SCHREINER and REED), A., ii, 420.
the respiratory pigments of (PALADIN), A., ii, 416.
liberation of carbon dioxide by dead parts of (NABOKICH), A., ii, 616.
function of calcium in (GRAFE and V. PORTHEIM), A., ii, 884.
Plants, chemical changes consequent on the wounding of (FRIEDRICH), A., ii, 774.
occurrence of salts of anhydro-oxymethylenediphosphoric acid or phytin in (SUZUKI and YOSHIMURA), A., ii, 124.
production and physiological rôle of pentosans in (CALABRESI), A., ii, 217.
green, the protein changes taking place in, when kept in the dark ( BUTKIEWITSC), A., ii, 834.
photosynthesis of carbon dioxide by (EWART), A., ii, 217.
hydrogen cyanide and the assimilation of nitrogen in (RAVENNA and PELI), A., ii, 217.
nitrate-reducing enzyme in (IRVING and HANKINSON), A., ii, 218.
higher, influence of micro-organisms on the utilisation of the insoluble phosphates by (DE GRAZIA and CERZA), A., ii, 216.
odoriferous, vegetation of (ROURE-BERTLAND FILS), A., ii, 417.
perennial, successive conditions of plant constituents during the normal development of a (ROURE-BERTLAND FILS), A., ii, 417.
detection of arbutin in (FICHENHOLZ), A., ii, 995.
employment of nitron for estimating nitrates in (LITZENDORFF), A., ii, 130.
Plasma, muscle. See Muscle plasma.
Plast ein (SAWJALOFF), A., i, 234; (LEVENE and VAN SLYKE), A., i, 932.
Platinichlorides, Platinocyanides, and Platinous chloride. See under Platinum.
Platinum, chemical decomposition of, by means of an alternating current (GROSS), A., ii, 199.
change of density and specific heat of, after treatment, and the dependence of the specific heat on the temperature (SCHLETT), A., ii, 563.
and arsenic, freezing point diagrams of the system (FRIEDRICH and LEROUX), A., ii, 300.
oxidisability of (MARIE), A., ii, 299.
passivity of (RÜER), A., ii, 601, 954.
colloidal, reduction catalyses with (PAAL and GERUM), A., i, 599.
and hydrogen, reduction with, at the ordinary temperature (WILLSTÄTER and MAYER), A., i, 383, 636.
Platinum alloys, detection of ruthenium in (ORLOFF), A., ii, 231.
with thallium (HACKSPILL), A., ii, 504.
Platinum alloys with tin (Podkopéeff), A., ii, 391.

Chloroplatinic acid, preparation of, by electrolysis of platinum black (Weber), A., ii, 391.

Platinous chloride, compounds of, with dicyclopentadiene (Hofmann and v. Nareut), A., i, 519.

Platinichlorides, optical investigation of the condition of (Hantzsch, Clark, and Meyer), A., ii, 447.

Platinocyanides (Levy), A., i, 252.
fluorescence of (Levy), T., 1446; P., 178.

Platinum-blue (Hofmann and Bugge), A., i, 141.

Platinum metals, detection of, by the metaphosphate bead (Donau), A., ii, 434.
“explosive,” physico-chemical researches on (Cohen and Strengers), A., ii, 299.

Plumbago, estimation of carbon in, by means of an electric furnace (Johnson), A., ii, 630.

Point discharge. See under Electrochemistry.

Poison, cobra, action of, in destroying complement (Morgenroth and Kaya), A., ii, 313.

snake, hemolysis by (V. Dungern and Coca), A., ii, 866.

Poisons, influence of certain, in the fibrillar contraction of the heart (Winterberg), A., ii, 521.

action of, on enzymatic processes (Santesson), A., ii, 1061.

of Ananita Phallidic (Abel and Ford), A., ii, 1061.

corrosive, post-mortem action of, in the stomach (Harnack and Hildebrandt), A., ii, 1062.

vegetable, detection of, in decomposed animal bodies (Panzer), A., ii, 997.

See also Hemolytic poisons.

Poisoning by atoxyl (Blumenthal and Heischmann), A., ii, 613.

by bismuth subnitrate (Böhme), A., ii, 55.

by bromobenzene, protein metabolism in (Marriott and Wolf), A., ii, 123.

cobra, and hemolysis (Bang), A., ii, 721.

by cresol (Blumenthal and Jacoby), A., ii, 55.

by lead and its detection (Schmidt), A., ii, 412.

by oleic acid (Faust), A., ii, 1062.

by phosphorus, chemistry of (Porges and Fikhram), A., ii, 721.

XCV. ii.

Poisoning by potassium chlorate (Riess), A., ii, 1062.

Polarimetric measurements and study. See under Photochemistry.

Polonium, extraction of, and its properties (Giesel), A., ii, 342; (Markwald), A., ii, 454.

α-particles, range of activity and absorption of (Aschkinass), A., ii, 920.

rays (Lattes), A., ii, 796.

Polyhydroxylaldehydes, partially alkylated, preparation of (Dreyfus), A., i, 654.

Polyiodides, formation of, in nitrobenzene solution (Dawson), T., 1305; P., 181; (Dawson and Jackson), T., 2063; P., 213.

Polymerisation, application of optical properties of liquids to the study of (Andreeff), A., ii, 547.

Polymorphism (Barlow and Pope), T., 1528; P., 193.

of liquids (Vorlander), A., ii, 22.

Polynitro-compounds, partial electrolytic reaction of, in presence of vanadium compounds (Hofe and Jakob), A., i, 869.

Polyoxymethylene, α-, β-, γ-, and δ- (Auerbach and Barschall), A., i, 131.

Polypeptidophosphoric acid (paranucleic acid) from caseinogen (Reh), A., i, 69.

Polypeptides, synthesis of (Fischer), A., i, 324, 544, 887; (Abderhalden and Guggenheim), A., i, 420, 535; (Fischer and Kropp), A., i, 773; (Kay), A., i, 773; (Fischer and Hirszowskii), A., i, 887; (Fischer and Scheibler), A., i, 957; (Fischer and Cone), A., i, 1004; (Fischer and Reif), A., i, 1007.

containing tryptophan (Abderhalden and Baumann), A., i, 932.

which contain tyrosine, action of tyrosinase on (Abderhalden and Guggenheim), A., i, 1030.

course of the fermentative degradation of (Abderhalden and Koelker), A., i, 483.

action of the juices expressed from cells on (Abderhalden and Lussana), A., i, 489.

action of the juice of Psalliotus campestis on (Abderhalden and Rilliet), A., i, 459.

cleavage of (Abderhalden and Koelker), A., i, 238.

behaviour of certain, towards the red corpuscles and platelets of ox-blood (Abderhalden and Manwaringo), A., ii, 510.

94
INDEX OF SUBJECTS.

Potassium, platinichloride, solubility of (Archibald, Wilcox, and Buckley), A., ii, 492.

chromates, behaviour of, at high temperatures (Groschüff), A., ii, 501.
dichromate, crystallisation of (Miers), A., ii, 388.
estimation of, in milk (Gouëre), A., ii, 325.
calcium chrome, dimorphism of (Rakowski), A., ii, 674.

hydroxide, alcoholic solution, preparation of a colourless (Halla), A., ii, 944.

preparation of, which will keep (Rabe), A., ii, 689.

preparation and apparatus for storing it (Scholl), A., ii, 425.

action of, on ketones (Montagne), A., i, 988.

periodate, specific gravity and solubility of (Barker), T., 16.

iodide, viscosity of non-aqueous solutions of (Getman), A., ii, 668.
solubility of, in water, and of water in, at low temperatures (Kremann and Kerschbaum), A., ii, 37.

action of, on antimonic acid in presence of hydrochloric acid (Kolb and Formhal's), A., ii, 599.

reaction between potassium ferricyanide and (Just), A., ii, 825.
effect of, on ptyalin (Neilson and Terry), A., ii, 612.
cubes, rapid valuation of (Fiora), A., ii, 735.

double salts of, with mercuric iodide and dimercuroiodocamphor in organic solvents (Marsh and Struthers), P., 266.

lead periodate, Wells', composition and formula of (Meldrum), P., 97.
polyiodide (Lami), A., ii, 762.
polyiodides (Foote and Chalker), A., ii, 586.

permanganate, reduction of solutions of, acidified with sulphuric acid in presence of mineral acids (Waryniski and Tcheichvili), A., ii, 936.
nitrate, crystallisation of (Jones), T., 1740; P., 196.

polymorphism of (Barlow and Pope), T., 1548.
nitrite, molecular volume of (Ray), T., 999; P., 75.

lead nitrites, complex (Meldrum), P., 97.

aluminium silicates (Weyberg), A., ii, 697.

thorium silicate (Duboin), A., ii, 288.

Polypeptides, behaviour of certain, towards the plasma of ox-blood (Abererand and McLester), A., ii, 511.

See also Amino-acids and Dipeptides.

Polyphenols, hydrogenation of (Sattner and Mailhe), A., i, 529.

Polyphosphates. See under Phosphorus.

Polysaccharides, formulæ of (Kilian), A., i, 320.

Polysulphides, inorganic, theory of (Erdmann), A., ii, 832.

organic (Holmberg), A., i, 308.

Porcelain, hot, validity of Paraday's law in the electrolysis of (Haber, Rieff, and Voigt), A., ii, 254.

Positive electrons. See under Electrochemistry.

Potable water. See under Water.

Potash bulb, new form of (Hill), P., 182.

Potassium, extraction of, from felspathic rock (Cushman and Hubbard), A., ii, 586.

radioactivity of (McLennan and Kennedy), A., ii, 750.

solutions of, in liquid ammonia (Ruff and Zedner), A., ii, 585.

as the source of helium in saline minerals (Strutt), A., ii, 923.

physiological function of, in vegetable organs (Stoklasa), A., ii, 417.

Potassium salts, viscosity of solutions of (Getman), A., ii, 464.

action of, on photographic plates (Levin and Rueer), A., ii, 448.

reciprocal compounds of, with sodium salts (Jänecke), A., ii, 808, 840.

Potassium ammoniostannate (Fitzgerald), A., ii, 114.

rhodium bromide, and chloride (Gutierrez and Hüttinger), A., ii, 200.

hydrogen carbonate, reaction of, with magnesium carbonate and water (Büchner), A., ii, 184.

chlorate, action of, on hauerie and pyrites (Spezia), A., ii, 861.

poisoning with (Riess), A., ii, 1062.

 perchlorate, detection of, in potassium chloride (Klobbie and Visser), A., ii, 627.

chloride, solubility of, in aqueous pyridine at 10° (Schroeder), A., ii, 277.

influence of, on the solubility of calcium hydroxide, and vice versa (Kernot, D'Agostino, and Pellegrino), A., ii, 568.

magnesium oxychloride formed by electrolysis of the residual solutions from the manufacture of, and its importance for the preparation of bromine (Hop), A., ii, 948.

Potassium platinochloride, solubility of (Archibald, Wilcox, and Buckley), A., ii, 492.

chromates, behaviour of, at high temperatures (Groschüff), A., ii, 501.
dichromate, crystallisation of (Miers), A., ii, 388.
estimation of, in milk (Gouëre), A., ii, 325.
Potassium silver silicomolybdate (Coreaux), A., ii, 379.
sulphate and magnesium sulphate
system (NACKEN), A., ii, 693.
compound of, with arsenic sulphate
(Kuhl), A., ii, 36.
copper and cadmium calcium sulphates
(D'Ans), A., ii, 590.
acid sulphates (Arzalier), A., ii, 763.
sulphide, compound of, with nickel
sulphide (I. and L. Bellucci), A.,
ii, 196.
sulphite, action of, on potassium
tetra thionate in aqueous solution
(Colefax), T., 798.
and potassium pentathionate, the
reaction between (Divers), P., 122.
thiocyanates (Donk), A., ii, 763,
859.
trithionate (Mackenzie and
Marshall), T., 1732; P., 199.
tetra thionate, action of potassium
sulphite on, in aqueous solution
(Colefax), T., 798.
Potassium cyanide, reaction of, with
o-nitrobenzaldehyde (Eekcrantz
and Ahlqvist), A., i, 347;
(Povovici), A., i, 550.
influence of, on nitrogen excretion
in dogs (Welker), A., ii, 411.
influence of, on protein metabolism
(Richards and Wallace), A., ii,
214.
influence of, on the respiration of
Aspergillus niger, with remarks on
the mechanism of the action of
hydrocyanic acid (Schroeder),
A., ii, 413.
ferricyanide, reaction between potassium
iodide and (Just), A., ii, 825.
ferricyanide, conditions of equilibrium
in the system, ferric chloride,
water, and (Volschini), A., ii,
468.
estimation of, volumetrically (Bollenbach),
A., ii, 996.
thiocyanate, reaction between ferric
chloride and (Bongiovanni), A.,
i, 770, 859.
action of imide chlorides on (John-
son and Storey), A., i, 837.
Potassium, volumetric estimation of, as
the cobaltinitrite (Druskel), A., ii,
66.
estimation of, by the platinit chloride
method (de Vries), A., ii, 430,
534.
estimation of, in dung, manures, soils,
and vegetable substances (Schienke),
A., ii, 321.
estimation of, in silicates (Auten-
rieth), A., ii, 897.
Potassium and sodium, estimation of, in
silicates (Thomsen), A., ii, 431.
estimation of, in soils (Ronnet), A.,
ii, 534.
application of the cobaltinitrite method
to the estimation of, in soils
(Druskel), A., ii, 735.
Potassium salt deposits, physico-chemi-
cal and mineralogical investigations
of the occurrence of bromine and iodine
in the (Boeke), A., ii, 500.
Potatoes, manuring experiments with
calcium cyanamide on (Stutzer),
A., ii, 726.
aman of manganese compounds on
(Gregoire, Hendrick, and Car-
piaux), A., ii, 529.
sodium nitrate compared with am-
onium sulphate for (Baessler),
A., ii, 127.
Potential differences. See under Electro-
chemistry.
Pozzuolana and mortar, microscopic
study of (Gallo), A., ii, 844.
Praseodymium salts, borax bead test
for (Milbauer), A., ii, 70.
Praseodymium fluoride (Povovici), A.,
ii, 283.
Prasindones (Keiimann and Schwars-
enbach), A., i, 297.
Precious stones, coloration of certain,
under radioactive influences (Ber-
thelot), A., ii, 8.
of the family of aluminides, formation
of (BordaS), A., ii, 191.
action of radium bromide on (Bor-
das), A., ii, 8.
Precipitates, possibility of determining
the mass of, by observation of their
rates of settling (Kohn), A., ii,
92.
clusion of soluble substances by
certain (Froin), A., ii, 477.
Pregnancy, amino-acids in urine during
(Van Leersum), A., ii, 715.
Pressure and temperature in relation
to orthobaric volumes (Haigh; Young),
A., ii, 813.
Pressures, apparent deviations from
Mariotte's law and their influence on
the measurement of small (Scheel
and Heune), A., ii, 1016.
Pressure cylinder, new (Pfyl and
Linne), A., ii, 270.
Proline (pyrrolidino-2-carboxylic acid),
synthesis of (Schienke and Ander-
sen), A., i, 676.
derivatives of (Fischer and Reif),
A., i, 1007.
Prolines, isomeric hydroxy-, and their
derivatives (Leuchs and Felsen), A.,
i, 510.
Propionyl-leucine anhydride (FISCHER and REIF), A., i, 1003.

Propaldehyde, α-amino-, p-nitrophenyl-

-Propenyldimethylacetal, α-bromo-

and β-iodo- (WOHL and SCHWEITZER), A., i, 942.

Propionaldehyde, a-amino-, p-nitrophenyl-

-Propenylphenetole, A., i, 323.

Propylaldehyde, dimethylacetal, p-bromo-

and β-iodo- (WOHL and SCHWEITZER), A., i, 942.

Propionic acid, vide Propargylcarbinol.

Propionic acid, α-bromo-, ethyl ester, condensation of, with cyclohexanones (WALLACH, EVANS, and MENDELSOHN-BARTHOLOGY), A., i, 403.

Propionic acid, α-bromo- and α-chloro-, glucinium salts (GLASMAN and NOVICKY), A., i, 121.

Propionic acid, vinyl-, See Lactic acid.

1-propioniatric acid, a-iodo- (ABDERHALDEN and GUGGENHEIM), A., i, 887.

Propionitrile, additive compound of, with silicon tetrabromide (REYNOLDS), P., 280.

Propionitrile, chloro-, preparation of (BERGEL and FEIGL), A., i, 140.

l-Propionoxyisatin (HELLER and SOKULIS), A., i, 208.

Propionyl chloride, α- and β-chloro-, and their p-toluidides (WOLFFENSTEIN and ROLLE), A., i, 282.

dl-Propionyl chloride, α-iodo- (ABDERHALDEN and GUGGENHEIM), A., i, 887.

Propionylalmine. See under the parent Substance.

Propionylbenzylpropionic acid, ethyl ester (DIECKMANN and KRON), A., i, 389.

γ-Propionylbutyric acid and its esters, oxime, and semicarbazone (BLAISE and MAIRE), A., i, 392.

Propionylglycylglycine and its ethyl ester, α-bromo- (FISCHER), A., i, 325.

d-Propionylglycylglycine, α-bromo-

(ABDERHALDEN and HIRSZOWSKI), A., i, 888.

Propionyllethalaminic acid and its ethyl ester and its semicarbazone (BLAISE and MAIRE), A., i, 391.

Propionylglycine, d-bromo- (FISCHER), A., i, 324.

Propionylglycylglycine, d-bromo-

(FISCHER), A., i, 325.

Propionyliminocyclohexane carboxylic acid, attempt to synthesise (STADNIKOFF), A., i, 265.

3-Propionyl-1-methyl-1H-cyclohexene and its semicarbazone (WALLACH and RENTSCHLER), A., i, 406.

Propionylphosphonic chloride, di-α-

chloro- (STEINKOFF and BENEDEK), A., i, 963.

β-Propionylpropionic acid and its semicarbazone and ethyl ester (MAIRE), A., i, 248.

Propionyltropane, αβ-dibromo- and α- and β-chloro-, and their additive salts (WOLFFENSTEIN and ROLLE), A., i, 282.
INDEX OF SUBJECTS.

Propionyl-1-tyrosine, a-bromo-, and its ethyl ester, and a-bromo-3:5-diiodo- (Abderhalden and Hirszowski), A., i, 888.

Propionyl-1-tyrosine, iso-derivatives (Abderhalden and Guggenheim), A., i, 887.

Propionyl-d-valine, d-a-bromo- (Fischer and Scheibler), A., i, 958.

Propiophenone, a- and b-amino-, salts of (Gabriel), A., i, 181.

Propiophenon-carbamide and -phenylthiocarbamide (Gabriel), A., i, 181.

Propyl alcohol, oxidation of, by a contact process (Orloff), A., i, 306.

iso-Propyl alcohol, dichloro-, and its benzyl derivative (Wohl and Roth), A., i, 942.

trichloro-, decomposition of (Mossler), A., i, 751.

Propyl arsinite (Lang, Mackey, and Gortner), T., 1367; P., 150.

chloride, action of ethylenamine on (Comanducci and Arena), A., i, 138.

cuprocyanide (Guillemand), A., i, 720.

cyclo-Propylacetic acid and its salts (Demjanoff and Dojarenko), A., i, 156.

r- and s-Propyladipic acid, preparation of (Blanc), A., i, 245.

s-Propylaminocetals and its derivatives (Paaal and van Gemmeren), A., i, 511.

s-Propylaminopyrines, 2- and 3-, and their derivatives (Michaelis and Mielecke), A., i, 62.

iso-Propyliso-butyrsuccinic acids, isomeric, and their salts and anhydrides (Fichter and Glaser), A., i, 660.

isoPropylcarbamide (Conduché) A., i, 155.

Propylcarboline (Guillemand), A., i, 719.

Propylcatechol, dichloro-, cyclic carbonates of (Barger), T., 2081; P., 237.

Propyltrichlorosilanes (Meler), A., i, 967.

B-n-propylcinnamic acid (Schroeter and Buchholz), A., i, 170.

4-isopropylidiphenyl-2:3-di-carboxylic acid (or 3-isopropylidiphenyl-2:4'-di-carboxylic acid) and its methyl ester and silver salt (Lax), A., i, 874.

Propiene oxonide (Harries and Haeffner), A., i, 846.

Propylenediamine and ethylenediamine, compounds of, with chromium and cobalt salts (Pfeiffer, Gassmann, and Pietsch), A., i, 508.

Propylenedicarboxylic acid. See Methacrylic acid.

n-Propyl-1-cyclohexene and its nitrosochloride, nitropropyridinide, and methoxyloxime and semicarbazone (Wallach, Churchill, and Rentschler), A., i, 405.

iso-Propyl-1-cyclohexene and its nitrosochloride and oxime (Wallach and Mallison), A., i, 406.

1-iso-Propylcyclohexen-2-one and its semicarbazone (Wallach and Mallison), A., i, 406.

1-iso-Propyl-1-and-2-cyclohexen-4-ones and their semicarbazones (Wallach and Heyer), A., i, 425.

iso-Propylideneacetone. See Mesityloxide.

Propylidenecyclohexane and its nitrosochloride, nitropropyridinide, and methoxyloxime (Wallach, Churchill, and Rentschler), A., i, 405.

iso-Propylidenecyclohexane (Wallach and Mallison), A., i, 406.

Propylidenephosphonic chloride, a&b-trichloro- (Steinkoff and Benedek), A., i, 963.

2-Propylimino-4-methyluracil, chloro- (Majima), A., i, 229.

iso-Propylmalonic acid, ethylester, sodium derivative, action of monochloromethyl ether on (Simonsen), T., 1777; P., 212.

isopropylmalonic acid, b-hydroxy-, b-lactone of, from acetone and malonic acid, and its salts (Meldrum), T., 598; P., 31.

iso-Propylmalonic acid, b-hydroxy-, its action of monochloromethyl ether on (Simonsen), T., 1777; P., 212.

iso-Propylmalonic acid, p-nitrophenyloxime, and its p-nitrophenylhydrazone and semicarbazone, and its isomeric (Blaise and Herman), A., i, 319.

n-Propynaphthalenes, a- and b-, and their picrates (Bargellini and Melacini), A., i, 775.

3-Propyliso-oxazoline (Maire), A., i, 200.

1-iso-Propylpentane, b-iodo- (Clarke), A., i, 493.

iso-Propyl cyclopentane, 3-amino- (Bouveyault and Blanc), A., i, 135.

iso-Propyl clysopentane, 3-carboxyamide (Bouveyault and Blanc), A., i, 135.

1-iso-Propyl-β-pentanol (Clarke), A., i, 493.

iso-Propyl cyclopentane-3-ol (Bouveyault and Blanc), A., i, 135.

1-iso-Propyl-β-pentanol (ethyldiospropylacetone) (Clarke), A., i, 493.

iso-Propyl cyclopentane-2-one and its carboxylic acid and their semicarbazones (Bouveyault and Locquin), A., i, 173.

iso-Propyl cyclopentane-3-one (Bouveyault and Blanc), A., i, 135.
1-isoPropylcyclopentan-2-one-3-carbonylic acid, ethyl ester (BOUVEAULT and LOQUIN), A., i, 173.

2-p-isoPropylphenyl-2:3-naphthacyl-oxaline and its additive salts, and 1-amino-, and its derivatives and compounds with aldehydes (FRANZEN and SCHUELMANN), A., i, 293.

α-cycloPropylpropylene (HENRY), A., i, 881.

3-Propylpyrazoline and its picrate and phenylcarbamide (MAIRE), A., i, 281.

4-Propylquinoline and its additive salts (BLAISE and MAIRE), A., i, 567.

isoPropylquinoline, new, and its picrate (VAN HOVE), A., i, 827.

Propyltheophyllines, ν- and iso-, and their additive salts (SCHWABE), A., i, 46.

β-isoPropylvaleric acid, 5-bromo-, ethyl ester (BLANC), A., i, 245.

β-isoPropylvalerolactone and its hydrazino-derivative (BLANC), A., i, 245.

Prosecretin in relation to diabetes mellitus (BAINBRIDGE), A., ii, 213.

Protagon (CRAMER and WILSON), A., i, 284; (ROSENHEIM and TEBB), A., i, 488.

optical activity of, and a new physical phenomenon observed in connexion with the optical activity of (ROSENHEIM and TEBB), A., ii, 879.

Protamine from salmon spermatozoa, composition of the (NELSON), A., i, 1030.

from the spermatozoa of the Caspian sturgeon (MALENUCK), A., i, 1030.

from the thymus gland (NELSON), A., i, 1030.

as a means of distinguishing primary from secondary proteoses (HUNTER), A., i, 488.

Protamines, chemistry of (MALENUCK), A., i, 1030.

compounds of, with other proteins (HUNTER), A., i, 71.

Proteic acids in blood (BROWINSKI), A., ii, 205.

Protein, a thermosoluble, said to be that of Bence-Jones, in urine (GRIMBERT), A., ii, 212; (GASCARD and DEVALMONT), A., ii, 519.

peptones from (ROGOZINSKI), A., i, 487.

antolytic and hydrolytic degradation of, under normal and pathological conditions (GLIKIN and LOEWY), A., ii, 714.

absorption of (V. KÜRÖSY), A., ii, 960.

assimilation of, introduced enterally (PRINGLE and CRAMER), A., ii, 709.

Protein, assimilation of, introduced parenterally (CRAMER), A., ii, 709.

cleavage products, nutritive value of (ABDERHALDEN and LONDON), A., ii, 81; (ABDERHALDEN and ONGER), A., ii, 981; (ABDERHALDEN), A., ii, 1051.

constitution (HUGOENENQ and MOREL), A., i, 706.

decomposition, influence of nitrogen-free sources of energy on the rate of, by the organism (FAITA and GIGON; PARI), A., ii, 961.

influence of the thyroid gland on the rate of (PARI), A., ii, 962.

ferment of the gastric juice, action of alkalies on (TICHOMIROFF), A., ii, 404.

formation in ripening seeds (WASSILIEFF), A., ii, 976.

hydrolysis, quantitative measurement of, by “formaldehyde titration” (SÖRENSEN), A., i, 115; (SÖRENSEN and JESSEN-HANSEN), A., ii, 234.

katabolism. See Katabolism.

metabolism. See under Metabolism.

nomenclature (REPORT OF A JOINT COMMITTEE OF THE AMERICAN PHYSIOLOGICAL SOCIETY and the AMERICAN SOCIETY OF BIOLOGICAL CHEMISTS), A., i, 301.

precipitation, calorimetric investigation on (HEELITZKA), A., ii, 706.

putrefaction, fatty acids of (NEUBERG and ROSENBERG), A., i, 116.

synthesis in animals (HENRIQUES), A., ii, 207.

Proteins, “specific dynamic action” of (LUSK), A., ii, 514; (ZUNTZ), A., ii, 606.

changes in internal friction in, due to degradation (SCHRÖR), A., ii, 931.

action in the dark of fluorescent substances on, and its reversibility (KUDO and JODLBAUER), A., ii, 867.

the so-called amide nitrogen of the (SKRAUP and V. HARDT-STREIMAYR), A., i, 584.

new method of hydrolysis of, by means of hydrofluoric acid (HUGOENENQ and MOREL), A., i, 706.

hydrolysis of, in pepsin-acid solutions (BERG), A., i, 374.

part played by alkali in the hydrolysis of, by trypsin (ROBERTSON and SCHMIDT), A., i, 843.

leucine fraction from the hydrolysis of (EHILICH and WENDEL), A., i, 302.

preparation of isoleucine from the hydrolytic products of (LEVENE and JACOBS), A., i, 375.
Proteins, action of nitrous acid on (TREVES and SALOMONE), A., i, 114. 
production of fat from (BODANOFF), A., ii, 206. 
and sulphur, the formation of hydrogen sulphide from (HILDEBRANDT), A., 
i, 709. 
rich in bases, digestion and absorption of (LONDON), A., ii, 870. 
digestion of, in the alimentary canal of the dog (ABBERHALDEN, LONDON, 
and OPLEER), A., ii, 514. 
behaviour of different, in the stomach and upper duodenum of the dog 
(LONDON and POLOWZOWA), A., ii, 960. 
influence of, on haemolysis (MEYER), A., ii, 513. 
katabolism of (HOFMEISTER), A., i, 1026. 
amphoteric, compounds of salt ions with (PAULI and HANDOVSKY), A., 
i, 707. 
of egg yolk (PLIMMER), T., 1500 ; P., 190. 
of horse-serum (MELANBY), A., ii, 117. 
idiosed, absorption of (V. FÜRTH and FRIEDMANN), A., ii, 1050. 
of maize, hydrolysis of the (OSBORNE and CLAPP), A., i, 115. 
native, electrical charge of (FIELD and TEAGUE), A., ii, 118. 
of rice (ROSENHEIM and KAJIURA), A., ii, 317. 
vegetable, action of the enzymes of gastric and pancreatic juices on 
(STUTZER and MERRES), A., ii, 404. 
compounds of, with protamines (HUNTER), A., i, 71. 
new reaction of (BARDACH), A., ii, 332. 
colour reactions of (FLEIG), A., ii, 1080. 
chloroamine reaction of (CROSS, BEVAN, and BRIGGS), A., i, 374. 
detection of, by means of formaldehyde 
(V. LIEBERMANN), A., ii, 995. 
separation of (HASLAM), A., i, 71. 
See also Serum proteins. 
Proteoses, occurrence of, in blood and 
urine (BORCHARDT), A., ii, 957. 
Proteoses in blood (FREUND), A., ii, 117, 512 ; (ABBERHALDEN), A., ii, 305. 
protamine as a means of distinguishing 
primary from secondary (HUNTER), A., i, 488. 
Protocatechualdehyde, cyclic carbonate 
of (PAULY), A., i, 423. 
Protocatechualdehyde cyanohydrin and 
its reduction (FABERWERKE VORM. 
MEISTER, LUCHS. & BRÜNING), A., i, 418. 
Protocatechualdehyde, electrolyte oxidation of (A. G. and F. M. PERKIN), 
T., 1196 ; P., 149. 
cyclic carbonate, preparation of 
(PAULY), A., i, 423. 
Protocatechuic acid, phenyl and 
methoxyphenyl esters, amide, and 
anilide (BARGER), T., 569. 
Protocurcumin methyl ether (CLARKE 
and JACKSON), A., i, 670. 
Protopine of Japanese Corydalis roots 
(MAKOSHI), A., i, 908. 
Protoplasmin, hydrolysis of (ETARD 
and VILA), A., i, 68, 584. 
Proustite from Colorado (VAN HORN), 
A., ii, 603. 
Prune, compounds of, with amino-com- 
pounds, and its sulphate and picrate 
(GrANDMouGIN and BodMer), A., i, 289, 572. 
hydroxy-, and its benzenesulphonyl 
ester (GRANDMouGIN and BodMER), 
A., i, 290. 
Pruneapilide (GRANDMouGIN 
and BodMER), A., i, 289. 
Prunus Pseudo-cerasus var. Sieboldii, 
new glucose side from the bark of 
(ASAHINA), A., i, 559. 
Pseudo-acids and their sodium salts, 
possible constitutional formule of 
(HALLER and MULLER), A., ii, 1001. 
and acids, comparison of, in pyridine 
solution (HANtZSCHaRD and CAldWELL), 
A., ii, 21. 
Psylla wax (SUNDVIK), A., i, 123. 
Psyllic acid and its salts (SUNDVIK), 
A., i, 123. 
Ptyalin, effect of potassium iodide on 
(NEILSON and TERRY), A., ii, 612. 
Pulegone, action of amyl nitrite on, 
in presence of sodium ethoxide (CLARKE, 
LAPWORTH, and WECHSLER), T., 37. 
action of magnesium methyl iodide on 
(Rupe and EMMeRICH), A., i, 536. 
isoPulegone, hydrocarbon from (Rupe 
and EBERT), A., i, 663. 
Pulegoneacetal (ARBUSOFF), A., i, 555. 
isoPulegonic acid, oxime and semicarb- 
azine of, and oxidation of the oxime 
(CLARKE, LAPWORTH, and WECHSLER), 
T., 38. 
aβ-Pulenenone and its semicarbazone 
and dichloro-, and its reduction pro- 
duct (AUwers and HESSENLAND), A., 
i, 556. 
aβ-Pulenenone, dichloro-, conversion of, 
into Δ13,14-dihydro-p-xylene (AUwers 
and HESSENLAND), A., i, 551. 
βγ-Pulenenone (1:4:4-trimethyl-Δ2-cyclo- 
hexen-3-one) and its semicarbazone and 
dichloro-, and βγ-Pulenenol (AUwers 
and HESSENLAND), A., i, 550.
Pulone (1:4:1-trimethylecyclohexan-3-one), 4-chloro-1:2-dihydroxy-, and its benzoyl derivative (Auwers and Hesseland), A., i, 551.

derivatives, synthesis of, from o-cresol (Auwers and Hesseland), A., i, 550.

Py South, circulating (Stoltzenberg), A., ii, 1028.

laboratory (Luther), A., ii, 270.

Sprengel vacuum, simple form of (Pollock), A., ii, 938.

Purgatives, saline. See Saline purgatives.

Purine bases, formation of pyrimidine derivatives from (Streuel), A., i, 66.

Pururogallincarboxylic acid and its salts and tetramethyl ether, and the methyl ester of the ether (A. G. and F. M. Perkin), T., 1188; P., 149.

Puruprogallonecarboxylic acid and its acetylation and tetramethyl ether, and the methyl ester of the ether (A. G. and F. M. Perkin), T., 1190; P., 149.

Pus, detection of indole in (Porcher), A., ii, 769.

Putrefaction, studies on (Rettger), A., ii, 215.

chemistry of (Ackermann), A., i, 10.

Putrescine (Ackermann), A., i, 10.

Putridine and its aurichloride (Ackermann), A., i, 10.

Putrine and its aurichloride (Ackermann), A., i, 10.

Pyknometer, new form of (Bousfield), T., 679; P., 69.

for small amounts of substances (Fischer), A., i, 545.

Pyrimidone. See 4-Dimethylamino-1-phenyl-2:3-dimethyl-5-pyrazolone.

spiroPyran derivatives, cyclic oxonium salts from (Decker and Felser), A., i, 906.

Pyranol salts related to brazilein and hæmatein, synthesis and constitution of (Perkin, Robinson, and Turner), T., 1085; P., 148.

from alkylated brazilein and hæmatein (Engels, Perkin, and Robinson), T., 1147.

Pyrazine derivatives, formation of, from quinoxalines (Gabriel and Sonn), A., i, 60.

Pyrazine, 2-amino-, and its additive salts, and 3-carboxylic acid (Gabriel and Sonn), A., i, 60.

Pyrazine-2:3-dicarboxylic acid and its methyl ester, salts, anhydride, di-amide, and imide (Gabriel and Sonn), A., i, 60.

Pyrazines, disubstituted, formation of (Gabriel and Lieck), A., i, 464.

Pyrazole series, lactones of the (Wolff and Schreiner), A., i, 291.

Pyrazolones, thio- (Michaelis, Dulk, Lehmann, and Pander), A., i, 688.

3-Pyrazolones (Michaelis, Stieglr, and Willert), A., i, 209.

Pyridazines, synthesis of (Paal and Köhn), A., i, 57.

Pyridine, some physico-chemical properties of mixtures of water and (Hartley, Thomas, and Appleby), T., 538; P., 22; (Dunstan and Thole), T., 561; P., 59.

equilibrium in the system, silver nitrate and (Kahlenberg and Brewer), A., ii, 469.

compounds, absorption spectra of (Furvits), A., ii, 745.

with chromatates (Briggs), A., ii, 113; (Parravano and Pasta), A., ii, 294.

with mercuric cyanide (Schroeder), A., i, 252.

with molybdenum thiocyanate (Rozenheim and Garfunkel), A., i, 615.

additive, with silicon tetrabromide (Reynolds), P., 280.

alkyl iodides and their conductivity (Schall), A., i, 736.

cobalt and nickel thiocyanates, action of iodine on (Pfeiffer and Tilgner), A., i, 614.

magnesium organic compounds, action of, on benzaldehyde (Oddo), A., i, 57.

methyl derivatives, chlorination of (Sell), T., 1993; P., 225.

reaction of, with sodium hydrogen sulphite (Bucharer and Schenkel), A., i, 452.

Pyridine, 3:5-dichloro-6, preparation and orientation of (Sell), T., 1996, 1997; P., 225.

2:3:5-trichloro-, orientation of (Sell), T., 2001; P., 225.

2-chloro-5-amino- (Mills and Widdows), T., 1379; P., 174.

dichlorodihydroxy-, formation of (Sell), T., 2000.

3-hydroxy-, additive compound of, with chloroacetic acid (Kirpal), A., i, 681.

Pyridineacetoacetic acid, a-cyano-, ethyl ester, betaine of (Benary), A., i, 601.
Pyridine bases, use of, as halogen carriers (Cross and Cohen), P., 15.
Pyridinebutaine, 3-hydroxy-, and its methyl ether (Kirpal), A., ii, 436.
Pyridine-2-carboxylic acid. See Picolinic acid.
Pyridine-3-carboxylic acid. See Nicotinic acid.
Pyridine-4-carboxylic acid. See iso-Nicotinic acid.
Pyridinecarboxylic acids, 2:6-substituted, action of methyl iodide on (Turnau), A., i, 912.
Pyridinecarboxylic acids, hydroxy-, betaines of (Kirpal), A., i, 681.
Pyridine-2:3-dicarboxylic acid. See Quinolinic acid.
Pyridine series, new betaines of the (Kirpal), A., i, 679.
2-Pyridone, 5-amino-, synthesis of, and its N-benzoyl derivative (Mills and Widdows), T., 1881; P., 174.
2-Pyridyl benzote, 5-amino-, N-benzoyl derivative of (Mills and Widdows), T., 1383; P., 174.
Pyrimidine derivatives in nucleic acid (Osborne and Weyl; Levene and Mandel), A., i, 376.
formation of, from purine bases (Sturel), A., i, 66.
Pyrimidine, 6-amino-, picrolonate of (Wheeler and Jameson), A., i, 253.
Pyrimidine synthesis, Traube's (Baum), A., i, 292.
Pyrimidines (Johnson and Heyl), A., i, 59; (Johnson) A., i, 692, 739; (Wheeler and Liddle), A., i, 692, 693; (Johns), A., i, 917; (Johnson, Clapp, and Martin), A., i, 835; (Johnson, Storey, and McCollum), A., i, 837; (Wheeler and Johns), A., i, 838; (Johnson and Clapp), A., i, 931; (Johnson and Derby), A., i, 1018.
Pyroles, 4-keto-compounds of (Michaelis and Engelhardt), A., i, 918.
ψ-Pyroles, nitroso-compounds of (Michaelis, Mielecke, and Lutze), A., i, 61.
Pyrites, action of potassium chloride on (Sperza), A., ii, 59.
estimation of copper in (Remondini), A., ii, 323.
Pyrites crystals, American (Kraus and Scott), A., ii, 115.
Pyrocatechol. See Catechol.
Pyrogallooldehyde, compound of, with aniline hydrochloride (Gattermann), A., 1, 31.
Pyreneconic acid (3-hydroxy-γ-pyrene), constitution of halogenated compounds of (Compagnon), A., i, 280.
Pyromellitic acid, constitution of the phthaloins (Silberrad), P., 209.
iso-Pyromucic acid, constitution of (Blaise and Gault), A., i, 714.
Pyromucylacetic acid. See Furfuroylacetic acid.
γ-Pyrene, 3-hydroxy-. See Pyreneconic acid.
2-Pyrene-6-carboxylic acid, 3-hydroxy- (Blaise and Gault), A., i, 714.
4-Pyrene compounds, formation of, from acetylenic acids (Ruhemann), T., 431, 1281; P., 52, 177.
Pyrones and allied compounds, relation between absorption spectra and chemical constitution of (Baly, Collie, and Watson), P., 268.
Pyronesyntheses by means of the "tertiary bases reaction" (Wedekind and Haeussermann), A., i, 671.
Pyroartaric acid, dibromo-, action of phenylhydrazine on (Fichter, Guggenheim, and Brasc), A., i, 105.
Pyrrhotite, recent formation of (Cornu), A., ii, 396.
Pyrrole derivatives and piperazine derivatives, synthesis of, from the three nitroanilines (Borsche and Tittsinger), A., i, 103.
pyroform, action of silicochloroform on (Reynolds), P., 279.
silicon compound of (Reynolds), P., 279.
Pyroles, reactions of (Angeli and Marchetti), A., i, 207.
Pyroles, nitroso- (Morelli and Marchetti), A., i, 383.
Pyrrolidine-2-carboxylic acid. See Proline.
Pyroldione derivatives, amino-, from mesityl oxide and from benzylideneacetone (Kohn), A., i, 829.
Pyrwine acid, ethyl ester, action of, on p-toluidine (Simon), A., i, 687, 738.

Q.
Quartz, chalcedony, and opal, relation between (Leitmeier), A., ii, 954.
change of state in, at 570° (Mügge), A., ii, 302.
Quartz tubes. See Tubes.
Quercetin methyl and trimethyl ethers and their acetyl derivatives (Wunderlich), A., i, 859.
INDEX OF SUBJECTS.

Quercitol, occurrence of (V. LITTMANN), A., ii, 124.

Quinidine. See 2-Methylquinoline.

Quinatoxins, pharmacology of the (HILDEBRANDT), A., ii, 577.

4-Quinazolone (4-hydroxyquinazoline), 7-nitro- (BOGERT and KLABER), A., i, 467.

Quinazolones (BOGERT and KLABER), A., i, 466.

Quinhydrone, absorption spectra of, in a state of vapour and in solution (HARTLEY and LEONARD), P., 284.

Quinic acid, calcium and zinc salts (GORTER), A., i, 346.

Quinine, behaviour of, in the body (GROSSER), A., ii, 213.

sulphate and acid persulphate (WOLFFENSTEIN and WOLFF), A., i, 283.

disulphate, direct application of Kerner's and of Liebig-Hesse's process to (BIGINELLI), A., ii, 783.

tannates. See under Tannic acid.

test for (VONDRASEK), A., ii, 997.

Quinizarin, condensation of, with aromatic amines (GRANDMOUGIN), A., i, 808.

diethyl-p-phenylenediamine and toluidine derivatives of (GRANDMOUGIN), A., i, 809.

o-Quinocatechol hemi-ether, heptachloro- (JACKSON and CARLETON), A., i, 428.

o-Quinodimethylhemiaceatalactechol ether, hexachloro-, preparation of (JACKSON and CARLETON), A., i, 428.

Quinol, absorption spectra of, in a state of vapour and in solution (HARTLEY and LEONARD), P., 284.

hydrogenation of (SABATIER and MAILHE), A., i, 529.

experiments on the oxidation of (V. EULER and BOLIN), A., ii, 1021; (WOLFF), A., ii, 1022.

reaction of diazonium salts with (ORTON and EVERATT), T., 1021; P., 118.

action of fused potassium hydroxide on (BLANKSMA), A., i, 262.

condensation products of (MEYER and WITTE), A., i, 670.

and arbutin, differentiation between (LEMAIRE), A., ii, 328.

dimethyl ether, sulphination of (SMILES and LE ROSSIGNOL), T., 760.

Quinol, tetrachloro- (hydrochloroanil), preparation and purification of (BOUVAILLY), A., i, 190.

Quinoline and its mononitro-derivatives, nitration of (KAUFMANN and HÜSSEY), A., i, 565.

reduction of, in presence of nickel oxide (IPATIEFF), A., i, 332.

Quinoline derivatives (REMEY and DECKER), A., i, 364.

of the anthraquinone series, preparation of (FARBEWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 365.

mechanism of the synthesis of (SIMON), A., i, 687.

alkyl iodides and their conductivity (SCHALL), A., i, 736.

glyoxaline bisulphite, amino- (HINSBERG), A., i, 453.

8-mercaptan and its benzoyl derivative, ethyl ether, and disulphide, and their 5-bromo-derivative (EDINGER), A., i, 363.

Quinoline, amino-derivatives, reaction of, with 1-chloro-2:4-dinitrobenzene (MEIGEN, GARBS, MERKELBACH, and WICHERN), A., i, 580.

6-chloro-, additive salts of (VOGNERICHTEN and HöFCHEN), A., ii, 914.

ol-hydroxy-, salts of, with polybasic acids (FRITZSCHE & CO.), A., i, 287.

2:4-dihydroxy-. See 4-Oxycarboxystyril.

8-thioycano- (EDINGER), A., i, 364.

Quinolines, mechanism of the reactions of Skraup and of Doebner and Miller in the formation of (BLAISE and MAIRE), A., i, 566.

Quinoline bases, action of acid esters on (SPADY), A., i, 915.

Quinoline-6-carboxylic acid, amide of, and its N-methyl derivative (EINHORN), A., i, 612.

Quinoline-2-carboxylic chloride (BESTHORN), A., i, 681.

Quinoline-6-carboxylicpiperidylmethylamide and its hydrochloride (EINHORN), A., i, 612.

Quinolinesulphonic acid, 8-hydroxy-, and its salts, preparation of (FRITZSCHE & CO.), A., i, 208.

Quinoline-5-sulphonic acid, 8-hydroxy-7-iodo-, double ammonium salt of (GRIESE), A., i, 454.

Quinoline-8-sulphonic acid and 5-bromo-, and their chlorides (EDINGER), A., i, 363.

Quinolinic acid (pyridine-2:3-dicarboxylic acid), 3-methyl ester, decomp. of (KIRPAL), A., i, 565.

Quinolylbenzotriazoles, 5-nitro- (MEIGEN, GARBS, MERKELBACH, and WICHERN), A., i, 580.

2-Quinolyl phenyl ketone (BESTHORN), A., i, 681.

4-Quinolyl phenyl ketone (REMEY and DECKER), A., i, 364.

o-Quinomethylhemiaceatalactechol ether, hexachloro-, preparation of (JACKSON and CARLETON), A., i, 428.

o-Quinone. See o-Benzquinone.
m-Quinone. See m-Benzquinone.

p-Quinone. See p-Benzquinone.

Quinone formation (VIDAL), A., i, 902.

Quinonedimethyli-immonium salts (WILLSTÄTTER and PICCARD), A., i, 476.

as-meri-Quinonedimethyli-immonium salts (WILLSTÄTTER and PICCARD), A., i, 476, 915.

Quinonemethylazones, relation between, and p-hydroxyazo-compounds (BORSHE), A., i, 69.

meri-Quinoneimines (WILLSTÄTTER and PICCARD), A., i, 475, 915.

Quinones and aldehydes, preparation of (LANG), A., i, 350.

aromatic, direct hydrogenation of (SABATIER and MAILHE), A., i, 278.

binuclear, as chromogens (DECKER), A., i, 805.

halochromism of (MEYER), A., i, 731; (KEHRMANN), A., i, 993.

and their oximes of the benzene series, condensation of, with nitro-derivatives of phenylhydrazine (BORSHE), A., i, 66.

Quinones, halogen derivatives, action of a-benzoylphenylhydrazine on (MC-PHERSON and DUBOIS), A., i, 461.

Quinonoid compounds (WILLSTÄTTER and PICCARD), A., i, 475, 915; (KEHRMANN), A., i, 699; (WILLSTÄTTER and MÜLLER), A., i, 731.

"Quinonoid dyes, binuclear" (DECKER), A., i, 805.

Quinonoid sulpho-derivatives (ZINCKE and BRUNE), A., i, 336.

Quinomeline derivatives, formation of pyrazines from (GABRIEL and SONN), A., i, 60.

Quinomeline, 2,3-dichloro- (MOTYLEWSKI), A., i, 371.

hydroxy-derivatives (HINSBERG), A., i, 694.

Quinomelines, relation of azines to (FISCHER and SCHINDLER), A., i, 221.

Rabies, action of various chemical reagents on the virus of (FERMI), A., ii, 412.

Racemic amines. See Amines.

amino-acids, resolution of, by yeast (EHRlich and WENDEL), A., i, 268.

compounds, existence of, in the liquid state (DUNSTAN and THOLE), T., 1815; P., 213.

triboluminescence of (GERNED), A., ii, 748.

Racemisation. See Autoracemisation.

Racemism. partial (LADENBURG and HERMANN), A., i, 364.

Radioactive substances, Radioactivity, Radiation, and Rays. See under Photochemistry.

Radiobacter and azobacter, the chemical changes involved in the assimilation of free nitrogen by (STOKLASA), A., ii, 880; (STOKLASA, ERNEST, STRAŠK, and VITEK), A., ii, 975.

Radio-leap (SZILÁRD), A., ii, 141.

Radiology. See under Photochemistry.

Radiotellurium. See Radium F.

Radiotherium, short-lived intermediate product between mesothorium and (HAHN), A., ii, 454.

Radium in Australian minerals (MASON and LARY), A., ii, 917.

in deep sea sediments (JOLY), A., ii, 649.

atomic weight of (WILDE), A., ii, 141, 1027; (THORPE), A., ii, 448.

what is? (FAUST), A., ii, 245.

production and origin of (RUTHERFORD), A., ii, 6.

preparation of, from pitchblende (HAINING and ULRICH), A., ii, 557; (FAWECK), A., ii, 917.

atom, certain properties of the (RIECKE), A., ii, 6.

life of (BOULTWOOD), A., ii, 551.

and uranium, relation between (SODDY), A., ii, 919.

heat developed by (V. SCHWEIDLER and HESS), A., ii, 919.

energy of (BORODOWSKY), A., ii, 448.

distribution in electric fields of the active deposits of (RUSZ), A., ii, 552.

emission of electricity from the induced activity of (DUANE), A., ii, 748.

influence of, on the electrolytic conductivity of colloidal solutions (ZŁOBCIK), A., ii, 451.

influence of, on the decomposition of hydroiodic acid (CROIGHTON and MACKENZIE), A., ii, 450.

action of, on the coloring of certain precious stones (BERTHELOT), A., ii, 8.
Radium, rate of production of helium from (Dewar), A., ii, 921.

formation of ozone by (Nasini and Levi), A., ii, 793.

emanation, spectrum of (Cameron and Ramsay), A., ii, 786; (Rutherford and Royds), A., ii, 787.

photographic impressions produced by (Muñoz del Castillo and Díaz de Rada), A., ii, 749.

volume of (Rutherford), A., ii, 791.

determination of the molecular weight of, by comparison of its rate of diffusion with that of mercury vapour (Perkins), A., ii, 552.

the initial change of the (Sidgwick and Tizard), P., 64.

measurement of the absorption coefficients of, in solutions and mixtures (Köfler), A., ii, 80; (Muñoz del Castillo), A., ii, 749.

direct action of, on copper and gold (Perman), T., 1775; P., 214.

action of, on solutions of copper salts (Curie and Gleditsch), A., ii, 793.

action of, on water (Cameron and Ramsay), T., 966, 992; P., 132, 133; (Rutherford and Royds), A., ii, 1006.

chemical action of, on water and certain gases (Cameron and Ramsay), T., 966; P., 132.

decay of, when dissolved in water (Moore), A., ii, 651.

condensation of water vapour in presence of (Curie), A., ii, 7, 797.

action of, in diabetes (Poulssoon), A., ii, 1057.

quantitative estimation of, in the atmosphere (Eve), A., ii, 7, 919; (Ashman; Satterly), A., ii, 918.

a-particles, scattering of, by matter (Geiger), A., ii, 795.

a-rays, the range of the (Duane), A., ii, 553.

secondary rays from the (Duane), A., ii, 554.

secondary rays, experiments on (Starke), A., ii, 341.

γ-rays, different kinds of, and the secondary γ-rays which they produce (Kleeman), A., ii, 553.

Radium bromide, action of, on precious stones of the family of aluminides (Bordas), A., ii, 8.

Radium-B and -C, decay of, at high temperatures (Schmidt), A., ii, 141; (Makower and Russ), A., ii, 449; (Engler), A., ii, 650.

Radium C, secondary γ-rays due to γ-rays of (Eve), A., ii, 795.

Radium D, E, F, occurrence of, in ordinary lead (Elster and Geitel), A., ii, 449.

separation of, from radio-lead (Szilárd), A., ii, 141.

Raffinose, hydrolysis of, by acids and enzymes (Armstrong and Glover), A., i, 712.

Rays. See under Photochemistry.

Reactions. See Affinity, chemical.

Red lead. See Triplumbic tetroxide under Lead.

Reducing sugars. See Sugars.

Reductase, rôle of, in alcoholic fermentation (Palladin), A., i, 589.

Reduction and oxidation of unsaturated organic compounds, catalytic reactions of (Fokin), A., i, 511.

with platinum and hydrogen at the ordinary temperature (Wilskat ter and Mayer), A., i, 383, 636.

Reflection spectra, infra-red. See under Photochemistry.

Refux condenser. See Condenser.

Refraction and Refractive power. See under Photochemistry.

Refractometric analysis. See under Analysis.

Refractometric researches. See under Photochemistry.

Regulator, simple, for high pressure gas (Le Rossignol), A., ii, 827.

Renal calculi (Rowlands), A., ii, 770.

Rennet, action of, on human milk (Bien enfeld), A., ii, 121; (Fuld and Wohlgemuth), A., ii, 311; (Engel), A., ii, 873.

Rennin (chymosin) and pepsin (Gewin), A., i, 71; (Bang), A., i, 236.

non-identity of, with pepsin (Hammarsten), A., i, 588.

probable chemical constitution of (Scala), A., i, 236.

Renosulphuric acid (Mandel and Neu berg), A., i, 1029.

Reptiles, chemistry of the liver and muscle of (Lyman), A., ii, 769.

Resacetophenone (2,4-dihydroxyacetophenone), action of phthalic anhydride on (Torrey and Brewster), A., i, 427.

derivatives (Dahse), A., i, 552.

dimethyl ether (Perkin, Robinson, and Turner), T., 1108.
Resacetophenonecarboxylic acid, synthesis of, and its esters and their hydrzones, and ethers (Liebermann and Lindembaum), A., i, 549.

Resacetophenonephenylhydrazone and its derivatives (Torrey and Kipper), A., i, 460.

Resacetophenonesemicarbazone (Torrey and Kipper), A., i, 461.

Residual affinity. See under Affinity, chemical.

Resin, a false euphorbium (Tschiirch and Leuchtenberger), A., i, 196.

of Antiaris toxicaria (Windaus and Welsch), A., i, 903.

of Pinus Jeffreyi (Tschiirch and Leuchtenberger), A., i, 196.

Resins from conifers (Schkateloff), A., i, 816.

from turpentine, method of obtaining, and the preparation from them of lacs, varnishes, &c. (Orloff), A., i, 815.

See also Copals, Grindelia, and Scammony resins.

Resin acid, dextrorotatory (Schkateloff), A., i, 890.

Resin oil (Schultze), A., i, 356.

Resodiacetophenone, azine, acetyl, and benzoyl derivatives, and phenylhydrzones and their derivatives (Torrey and Kipper), A., i, 461.

Resofavin (Herzig and Epstein), A., i, 899.

and its analogue from gallic acid (Herzig, Tschirnke, Epstein, and v. Bronneck), A., i, 547.

Resoquinone. See m-Benzoquinone.

Resorcinol, melting point of (Bennett), A., i, 529.

azo-derivatives of (Orton and Everett), T., 1017; P., 118.

diethyl ether (1:3-diethoxybenzene), 2:4-di- and 2:4:6-tri-nitro- (Blanksma), A., i, 158.

dimethyl ether (1:3-dimethoxybenzene), 5-nitro-, nitration of (Blanksma), A., i, 979.

4:6-dinitro-2-cyano- (Blanksma), A., i, 271.

Resorcinol, 2:4:6-trinitro-. See Styphnic acid.

mono- and di-nitroso-, successive preparation of, and of resorubin (Barberio), A., i, 161.

Resorcylaldehyde and chloro-, and their derivatives, synthesis of (Gattermann), A., i, 30.

Resorubrin, successive preparation of mono- and di-nitrosoresorcinols and of (Barberio), A., i, 161.

Respiration and circulation, effects of excess of carbon dioxide and want of oxygen on (Hill and Flack), A., ii, 706.

regulation of (Scott), A., ii, 865.

influence of oxygen on (Pembrey and Cook), A., ii, 706.

anaerobic, without the formation of alcohol (Kostytscheff), A., ii, 416.

Cheyne-Stokes (Pembrey), A., ii, 204.

cutaneous (Franzini and Preti), A., ii, 509.

Respiratory metabolism of the isolated spinal cord of the frog (Winterstein), A., ii, 509.

Respiratory tract, absorption of poisonous gases by the (Lehmann, Wiener, Willke, and Yamada), A., ii, 771.

Retene, structure of (Lux), A., i, 873.

Reyerite from Greenland (Boeggild), A., ii, 399.

Rhamnose-o- and -nitrophenylnitroazones (Reclaire), A., i, 1014.

Rhamnosides (Schmidt), A., i, 437.

Rhamnus Frangula and R. Purshiana, barks of (Tschiirch and Pool), A., ii, 886.

Rhapontic acid (Hesse), A., ii, 420.

Rhapontigenin and its triacetyl derivative and its Rhapontigenin (Hesse), A., ii, 419.

Rhapontin and its penta- and hexaacetyl derivatives (Hesse), A., ii, 419.

Rhein and its acetyl, sodium, and potassium derivatives (Hesse), A., i, 439.

Rheum austriacum and R. Rhaponticum, roots of (Hesse), A., ii, 418.

Rhiocoleic acid and its salts (Schröter, Weitzenböck, and Witt), A., i, 532; (Schröter and Weitzenböck), A., i, 636, 900.

nature and constitution of (Schröter and Weitzenböck), A., i, 900.

Rhodamic acid, 3-amino-, and its condensation with aldehydes (Andreasch), A., i, 684.

Rhodamic acids, substituted, and their condensation with aldehydes (Andreasch), A., i, 683.

Rhodanides of inorganic radicles, constitution and properties of (Dixon and Taylor), T., 2148; P., 238.

Rhodaninacetic acid (3-carboxymethylrhodaninic acid, 4-keto-2-thiohiazolotin-3-acetic acid) and its esters (Körner), A., i, 510.

and its salts, and its condensation with aldehydes (Andreasch), A., i, 684.

Rhodium, wave-length tables of the arc and spark spectra of (British Association Reports), A., ii, 334.
INDEX OF SUBJECTS.

Rhodium halogen salts, double (Gutbier and Hüttlinger), A., ii, 200.

Rhodium crucible, use of, in chemical operations (Crookes), A., ii, 702.

Rhodoclaidonic acid (Zoff), A., ii, 526.

Rhodonite—wollastonite, freezing point curve for the system (Ginsberg), A., ii, 842.

Rhodophyllins (Willstätter and Pfannenstiel), A., i, 198.

Rhodusite from Assikys River, Siberia (Iskulell), A., ii, 401.

Rhubarb and allied substances, compounds from (Hesse), A., i, 438; ii, 418.

L-Ribose, isolation of (Blanksmaj and Alberda van Ekenstein), A., i, 951.

Rice, proteins of (Rosenheim and Kajura), A., ii, 317.

starch. See Starch.

straw, composition of (Takucechi), A., ii, 617.

Rizopatronite from Minasragra (Bravo), A., ii, 703.

Rock analyses, estimation of ferrous oxide in (Mauzelius), A., ii, 538.

Rock-rose oil (Haensel), A., i, 665.

Rock salt, blue (Cornu), A., ii, 396.

artificial dichromism of (Siedentoff), A., ii, 4.

Rocks, influence of fine grinding on the water and ferrous iron content of (Hillebrand), A., ii, 778.

estimation of small amounts of barium in (Langley), A., ii, 985.

Röntgen rays. See under Photocchemistry.

Rongalite (sodium formaldehydesulph-

-oxydate), bases, and formaldehyde (Binz and Isaac), A., i, 940.

constitution of (Orloff), A., i, 132.

Rongalitic acid, bases, and formaldehyde (Binz and Isaac), A., i, 940.

Rosamine, the chromogen of the simplest (Kehrmann and Dengler), A., i, 1002.

Rosindone, constitution of (Kehrmann and Stern), A., i, 220.

Rosindone, constitution of (Kehrmann and Stern), A., i, 220.

Rosocyanin and its salts, acetyl derivative, and methyl ether (Clarke and Jackson), A., i, 670.

Rotation and Rotatory dispersion, polarisation, and power. See under Photocchemistry.

Rottlerin and its reactions (Herrmann), A., i, 99.

Roussin's salts (Bellucci and de Cesariis), A., ii, 111.

constitution of (Cambi), A., ii, 41, 288.

See also Ferronitrosulphides.

Rubber, Para, oxydase in (Spence), A., ii, 774.

latex, influence of the medium on Brownian motions in (Henri), A., ii, 760.

See also Caoutchouc.

Rubber tubing, absorption of gases by (Ditmar), A., ii, 159.

Rubidium rhodium bromide and chloride (Gutbier and Hüttlinger), A., ii, 200.

dichromate (Wyrouboff), A., ii, 181; (Stortenbecker), A., ii, 494.

iodate and periodate (Barker), T., 15.

polyiodides (Foote and Chalker), A., ii, 586.

nitrate, crystallisation of (Jones), T., 1742; P., 196.

calcium sulphates (D'Ans and Zeh), A., ii, 104.

trithionate (Mackenzie and Marshall), T., 1735; P., 199.

Rubidium syngenite (D'Ans-and Zeh), A., ii, 104.

Rucorcurcin and its acetyl derivative (Clarke and Jackson), A., i, 670.

Ruby, spectrum of the (Miethe), A., ii, 139.

Rue anemone, abnormal biochemical products of (Beattie), A., ii, 1065.

Rufiquebracho acid (Nierenstein), A., i, 40.

Ruthenium, detection of, in platinum alloys (Orloff), A., ii, 231.

Rutin (Schmidt; Wunderlich), A., i, 438.

from Camparisis spinosa and Globularia Alyssum (Wunderlich), A., i, 559.

from Polygoneum Fagopyrum, and its acetyl derivative (Wunderlich), A., i, 559.

Eye, effect of commercial sodium nitrate on (de Grazia), A., ii, 420.

gliadin from. See under Gliadin.

S.

Sabina ketone, preparation and transformation of, and its semicarbazone (Wallach and Heyer), A., i, 424.

Saccharides. See Disaccharides and Polysaccharides.
Saccharimeters, normal tubes for (ROUSSET), A., ii, 73; (PELLET), A., ii, 235.

"Saccharin." See o-Benzoesulphinide.

Saccharin and alkali saccharinates (RIMBACH and HEITEN), A., ii, 394.

Saccharine liquids, estimation of lactic acid in (LEGLER), A., ii, 438.

Saccharinic acid, alkali salts, and saccharin (RIMBACH and HEITEN), A., i, 394.

Safrole, (soSafrole), (GRANDMOUGIN and GUISSAN), A., i, 926; (GRANDMOUGIN and FREIMANN), A., i, 1024.

Saccharinic acid, (NEF), A., i, 8; (KILIANI), A., i, 128, 246.

Saccharin. See Sucrose.

Saffron, constituents of (PFYL and SCHETZ), A., ii, 979.

Safrole and di- and tri-bromo-, action of phosphorus pentachloride on (HOERING and BAUM), A., i, 527.

Salicylic acid, a part in the synthesis of (MOLL VAN CHARANTE), A., i, 175.

Salicylic acid, substances which play a part in the synthesis of (MOLL VAN CHARANTE), A., i, 175.

Salicylic acid, action of ferric salts on (HOPFGARTNER), A., i, 891.

Salicylic acid, resorbed, action of, on blood serum (JACOBY), A., ii, 512.

Salicylic acid, influence of, on the osmotic functions of the serum (JACOBY and SCHÜTZE), A., ii, 511.

azo-compounds of (GRANDMOUGIN and GUISSAN), A., i, 926; (GRANDMOUGIN and FREIMANN), A., i, 1024.

Hydrazine compound of (FRANZEN and EICHLER), A., i, 881.

Salicylic acid, crude and chinonine salts, and their optical activity (HILDITCH), T., 1391; P., 186.

Sage oil from Grasse (ROURE-BERTRAND FILS), A., i, 553.

Saindon. See Behenic acid, iodo-, calcium salt.

Sakuranin and its acetyl and benzoyl derivatives from the bark of Prunus Pseudo-cerasus var. Sieboldii and SAKURANETIN (ASAHINA), A., i, 559.

SAL ammoniacal. See Ammonium chloride.

Saladin, physiological action of (OMI; KUSUMOTO), A., ii, 613.

Salicylaldehyde, testing the purity of (KREIS), A., ii, 234.

condensation of, with benzamide (TITHERLEY and MARPLES), T., 1933; P., 229.

sodium derivative, and bromoethyl ether and its phenylhydrzone (HEHRING), A., ii, 557.

Salicylsalicyclic acid, alkylation of (IRVINE and MOODIE), T., 192.

Salicylic acid, (o-hydroxybenzoic acid), preparation of, from 2-cyclohexanol-1-carboxylic acid, and its 3-bromo-derivative (KÖTZ and GÖTZ), A., i, 173.

Salicylic acid, substances which play a part in the synthesis of (MOLL VAN CHARANTE), A., i, 175.

Salicylic acid, action of ferric salts on (HOPFGARTNER), A., i, 891.

Salicylic acid, resorbed, action of, on blood serum (JACOBY), A., ii, 512.

Salicylic acid, influence of, on the osmotic functions of the serum (JACOBY and SCHÜTZE), A., ii, 511.

azocompounds of (GRANDMOUGIN and GUISSAN), A., i, 926; (GRANDMOUGIN and FREIMANN), A., i, 1024.

Hydrazine compound of (FRANZEN and EICHLER), A., i, 881.

the supposed phenylhydrazone of (MEYER), A., i, 176.

the supposed phenylhydrazone of (MEYER), A., i, 176.

detection and estimation of, in foods (V. GENEREWSCH), A., ii, 906.

Salicylic acid, crude and chinonine salts, and their optical activity (HILDITCH), T., 1391; P., 186.

Sage oil from Grasse (ROURE-BERTRAND FILS), A., i, 553.

Saindon. See Behenic acid, iodo-, calcium salt.

Sakuranin and its acetyl and benzoyl derivatives from the bark of Prunus Pseudo-cerasus var. Sieboldii and SAKURANETIN (ASAHINA), A., i, 559.

SAL ammoniacal. See Ammonium chloride.

Saladin, physiological action of (OMI; KUSUMOTO), A., ii, 613.

Salicylaldehyde, testing the purity of (KREIS), A., ii, 234.

condensation of, with benzamide (TITHERLEY and MARPLES), T., 1933; P., 229.

sodium derivative, and bromoethyl ether and its phenylhydrzone (HEHRING), A., ii, 557.

Salicylsalicyclic acid, alkylation of (IRVINE and MOODIE), T., 192.

Salicylic acid, (o-hydroxybenzoic acid), preparation of, from 2-cyclohexanol-1-carboxylic acid, and its 3-bromo-derivative (KÖTZ and GÖTZ), A., i, 173.

Salicylic acid, substances which play a part in the synthesis of (MOLL VAN CHARANTE), A., i, 175.

Salicylic acid, action of ferric salts on (HOPFGARTNER), A., i, 891.

Salicylic acid, resorbed, action of, on blood serum (JACOBY), A., ii, 512.

Salicylic acid, influence of, on the osmotic functions of the serum (JACOBY and SCHÜTZE), A., ii, 511.

azocompounds of (GRANDMOUGIN and GUISSAN), A., i, 926; (GRANDMOUGIN and FREIMANN), A., i, 1024.

Hydrazine compound of (FRANZEN and EICHLER), A., i, 881.

the supposed phenylhydrazone of (MEYER), A., i, 176.

detection and estimation of, in foods (V. GENEREWSCH), A., ii, 906.

Salicylic acid, crude and chinonine salts, and their optical activity (HILDITCH), T., 1391; P., 186.

Sage oil from Grasse (ROURE-BERTRAND FILS), A., i, 553.

Saindon. See Behenic acid, iodo-, calcium salt.

Sakuranin and its acetyl and benzoyl derivatives from the bark of Prunus Pseudo-cerasus var. Sieboldii and SAKURANETIN (ASAHINA), A., i, 559.

SAL ammoniacal. See Ammonium chloride.

Saladin, physiological action of (OMI; KUSUMOTO), A., ii, 613.

Salicylaldehyde, testing the purity of (KREIS), A., ii, 234.

condensation of, with benzamide (TITHERLEY and MARPLES), T., 1933; P., 229.

sodium derivative, and bromoethyl ether and its phenylhydrzone (HEHRING), A., ii, 557.

Salicylsalicyclic acid, alkylation of (IRVINE and MOODIE), T., 192.

Salicylic acid, (o-hydroxybenzoic acid), preparation of, from 2-cyclohexanol-1-carboxylic acid, and its 3-bromo-derivative (KÖTZ and GÖTZ), A., i, 173.

Salicylic acid, substances which play a part in the synthesis of (MOLL VAN CHARANTE), A., i, 175.

Salicylic acid, action of ferric salts on (HOPFGARTNER), A., i, 891.

Salicylic acid, resorbed, action of, on blood serum (JACOBY), A., ii, 512.

Salicylic acid, influence of, on the osmotic functions of the serum (JACOBY and SCHÜTZE), A., ii, 511.

azocompounds of (GRANDMOUGIN and GUISSAN), A., i, 926; (GRANDMOUGIN and FREIMANN), A., i, 1024.

Hydrazine compound of (FRANZEN and EICHLER), A., i, 881.

the supposed phenylhydrazone of (MEYER), A., i, 176.

detection and estimation of, in foods (V. GENEREWSCH), A., ii, 906.

Salicylic acid, crude and chinonine salts, and their optical activity (HILDITCH), T., 1391; P., 186.

Sage oil from Grasse (ROURE-BERTRAND FILS), A., i, 553.
Salicylideneamidines (Francesconi and Cusmano), A., ii, 100.

Salicylidenediamine, di and tri-benzoyl derivatives of (Titherley and Mappes), T., 1940 ; P., 229.

Saline purgatives, inefficiency of, when injected subcutaneously or intravenously (Auer), A., ii, 213.

Saliva and oxygen supply (Carlson and McLean), A., ii, 118.

effect of diet on the amylolytic power of (Neilson and Lewis), A., ii, 709.
nitrites of, and their origin (Ville and Mestrezat), A., ii, 605.
of the cat, dextrose in (Carlson and Ryan), A., ii, 403.

the diatase in (Carlson and Ryan), A., ii, 606.

human, origin of the saccharifying power of (Mestrezat), A., ii, 605.
detection of thiocyanic acid in (Pollacci), A., ii, 782.

Salmon spermatozoa, composition of the protamine from (Neilson), A., i, 1080.

Salt. See Rock salt and Sodium chloride.

Salt formation, examination of the conception of hydrogen ions in (Lathwatt), T., 2187 ; P., 275.

Salt glycosuria. See under Diabetes.

Salts, formation of, and basicity of acids (Bruni), A., ii, 935, 1012.

conductivity and ionisation of, in aqueous solutions at high temperatures (Noyes, Melcher, Cooper, Eastman, and Kato), A., ii, 847.

containing water of crystallisation, thermodynamics of (Schottky), A., ii, 1016.

hydrolysis of (Rosenstiehl), A., ii, 164.

electrometric determination of the hydrolysis of (Denham), T., 41.

hydrolysis of, as illustrated by heats of neutralisation (Valey), A., ii, 812.

hydrolysis of, in solution ; lecture experiment (Vanzetti), A., ii, 805.

influence of, on hydrolysis, and the determination of hydration values (Armstrong and Crothers), A., ii, 816.

reciprocal pairs of (Jäncke), A., ii, 808, 841.

abnormal (Korczyński), A., i, 977.

complex, constitution of, and a criticism of Werner's theory (Friend), T., 1006 ; P., 122.

Salts, inorganic, adsorption phenomena of (Wöhlers), A., ii, 819.

sparingly soluble, saturated aqueous solutions of; the amounts dissolved and their alteration with temperature (Kohlrausch), A., ii, 814.

Silicon, estimation of commercial; separation of silica and (Limmer), A., ii, 131.
INDEX OF SUBJECTS.

Silver ammonium chromate (Gröger), A., ii, 691.

halides, attempt to produce dichroism by pressure in (Cornu), A., ii, 647.

and thiocyanate, relative solubilities of (Hill), A., ii, 378.

sub-halides (Trivelli), A., ii, 1036.

iodide, solubility of, in ammonia (Baubigny), A., ii, 691.

adsorption of silver nitrate and potassium iodide by amorphous (Lottermoser and Rothe), A., ii, 364.

nitrato, equilibrium in the system, pyridine and (Kahlenberg and Brewer), A., ii, 469.

action of, on chloroaucic acid (Jacobsen), A., ii, 601.

action of, on inorganic hydroxides (Biltz and Zimmermann), A., ii, 104.

nitrate, molecular volume of (Ray), T., 999; P., 75.

oxide in ammoniacal solution, explosion of vessel containing (Mattison), A., ii, 587.

reduction of, by hydrogen (Kohlshütter), A., ii, 182.

peroxide, so-called (Babrovský and Kuzma), A., ii, 378.

selenide, compounds of, with selenides of antimony, arsenic and bismuth (Pélabon), A., ii, 587.

potassium silicomolybdate (Copaix), A., ii, 379.

sulphate and silver sulphide, reaction between (Sackur), A., ii, 1036.

germanium sulphide. See Argyrodite.

Silver, new test for (Gregory), P., 125.

detection of, by the metaphosphate bead (Donau), A., ii, 434.

estimation of, volumetrically (Lang and Woodhouse), T., 1037; P., 122.

copper, and lead, estimation of, in complicated organic salts (Rindt and Simonis), A., ii, 432.

electrolytic separation of copper and (Gillett), A., ii, 226.

quantitative separation of thallium from (Spencer and Le Pla), T., 358; P., 75.

Silver assaying, apparatus for the prevention of acid fumes in (Dard), A., ii, 72.

Silver and lead assays, dry, in ores (Loevy), A., ii, 323.

Silver film, transparent (Turner), A., ii, 1034.

Silver group, microchemical analysis of the (Schoorl), A., ii, 432.
INDEX OF SUBJECTS.

Sodium bromide and iodide, colloidal (PAAL and KÜHN), A., ii, 179.
side, new reaction for the production of (CRISPO), A., ii, 840.
and oxalic acid solutions, ready means of comparing (TIAN), A., ii, 985.
hydrogen carbonate, carbon dioxide, sodium phosphate, and disodium phosphate, equilibrium between, at body temperature (HENDERSON and BLACK), A., ii, 467.
chloride, and barium and copper chlorides, and water, the system (SCHREINEMAKERS and DE BAAT), A., ii, 1020.
and hydrochloric acid, chemical and physiological properties of a solution of (PETERS), A., ii, 411.
colloidal (PAAL and KÜHN), A., ii, 179.
excretion of, in phloridzin diabetes (BIBERFELD), A., ii, 972.
See also Rock salt.

Soda and Salts.

Sodium, volatile, resonance spectra of (WOOD), A., ii, 546.
Sodium fluoride of (ZICKENDRAHT), A., ii, 910.
Sodium hydrocarbonate of (BERNINI), A., ii, 255.
Sodium, apparent molecular weight of, dissolved in liquid ammonia (KRAUS), A., ii, 834.
Sodium, atom, existence of positive electrons in the (WOOD), A., ii, 150.
Sodium, solutions of, in liquid ammonia (RUFF and ZEDNER), A., ii, 585.
Sodium, use of, as a desiccating agent for gases (MATIGNON), A., ii, 377.
Sodium, importance of, for sugar beet (ANDRIK and URBAN), A., ii, 219.

Hydrosulphide and thiosulphate, anhydrous, preparation of (VEREIN CHEMISCHER FABRIKEN IN MANNHEIM), A., ii, 689.

Hydroxide, estimation of, volumetrically, in presence of sodium carbonate (ANDERSEN), A., ii, 985.

Hypobromite, characteristic colour reactions produced by (DEHN and SCOTT), A., i, 780; (DEHN), A., ii, 907.

Hypochlorite; properties of the electrolytic bleaching solution (PUSCH), A., ii, 492.

Hyposulphite (HYDROSULPHITE), constitution of (ORLOFF), A., i, 132.
action of, on nitro-derivatives (SEYWETZ and NOEL), A., i, 408.
Sodium hyposulphite, aniline, and formaldehyde, interaction of (GESELLSCHAFT FÜR CHEMISCHE INDUSTRIE IN BASEL), A., i, 151.

application of, in volumetric analysis (BOLLENBACH), A., ii, 229.

periodate, specific gravity of (BARKER), T., 17.

iodide cubes, rapid valuation of (FIORA), A., ii, 785.

molybdate and d-tartaric acid, formation of compounds in solutions of (QUINET), A., i, 713; (GROSSMANN), A., i, 854.

molybdates, anhydrous (GROSCHUff), A., ii, 501.

nitrates, polymorphism of (BARLOW and POPE), T., 1528; P., 193.

and lead nitrate, the temperature of spontaneous crystallisation of mixtures of (ISAAC), T., 384; P., 30.

as manure (NAZARI), A., ii, 1068.

commercial, effect of, on rye (DE GRAZIA), A., ii, 420.

ammonium salts, and calcium cyanamide, manural experiments with (WAGNER, HAMANN, and MÜNZIGER), A., ii, 622.

and ammonium sulphate, manural experiments with (BESSELL), A., ii, 127; (CLAUSEN), A., ii, 981.

and calcium cyanamide, action of, on mangolds (KLÖPPEL), A., ii, 619.

action of organic nitrogen manures as compared with (POPP), A., ii, 727.

nitrites, molecular volume of (RÁY), T., 999; P., 75.

oxide, heat of combination of, with acidic oxides (MIXTER), A., ii, 929.

di- and tri-oxide carbonates (WOLFENSTEIN and WELTER), A., ii, 180.

peroxide (or dioxide) and ammonium persulphate, reaction between (KEMPF and OEHLER), A., ii, 704.

action of, on gold (MEYER), A., ii, 47.

and metallic sulphides, use of, for decomposing minerals and industrial products (WALTON and SCHOLZ), A., ii, 782.

oxidising power of, and its use in qualitative analysis (CALHANE), A., ii, 635.

use of, in qualitative analysis (CARON and RAUET), A., ii, 630.

use of, in quantitative analysis (PARK), A., ii, 628.

analysis of (NIEMEYER), A., ii, 132.

Sodium phosphate, disodium phosphate, sodium hydrogen carbonate, and carbon dioxide, equilibrium between, at body temperature (HENDERSON and BLACK), A., ii, 467.

ferripyrophosphate, ferripyrophosphate, and ferro- and ferri-metaphosphates (PASCAL), A., ii, 193.

silicate, interactions of, with metallic salt solutions (JORDIS and HENNIS), A., ii, 291.

sulphate solutions, spontaneous crystallisation of (HARTLEY, JONES, and HUTCHINSON), T., 825; P., 70.

and barium chloride, antagonistic action of, on the heart action (SCAFFIDI), A., ii, 520.

and magnesium sulphate system (NACKEN), A., ii, 693.

sulphide, estimation of, volumetrically (PODRESCHETNIKOFF), A., ii, 66.

sulphite, detection of, in presence of sulphate and thiosulphate (WESTON and JEFFREYS), A., ii, 320.

thioantimonate (DONK) A., ii, 763.

thioantimonate and thiosulphate, mixtures of, in water (DONK), A., ii, 955.

thioantimonates (DONK), A., ii, 859.

thiosulphate, the chemical dynamics of the reactions of organic halogen compounds and (SLATOR and TWISS), P., 286.

titration of (MILOBENSKI), A., ii, 130.

Sodium alkyl compounds and syntheses therewith (SCHORIGIN), A., i, 866, 881, 886.

alkyl thiosulphates, action of alkalis on (PRICE and TWISS), T., 1395, 1403; P., 179, 185.

o-, m-, and p-nitrobenzyl thiosulphates and the action of alkalis on (PRICE and TWISS), T., 1403; P., 185.

Sodium and potassium, estimation of, in silicates (THOMSEN), A., ii, 431.

Soil, physico-chemical processes in the production of (ROHLAND), A., ii, 59, 620.

influence of plant constituents on the chemical and physical properties of (ZAILE and WILK), A., ii, 60.

composition of the air in (LAU), A., ii, 888.

distribution of solute between water and (CAMERON and PATTON), A., ii, 126.

influence of solubility on availability in (DAIKUHARA), A., ii, 128.

constituents, effect of lime on the availability of (GUTHRIE and COHEN), A., ii, 889.
Soil, changes of availability of nitrogen in (Loew and Asö), A., ii, 621.
the Dyer method for the determination of plant food in (Shutt and Charbon), A., ii, 733.
chemical and bacteriological effects of liming (Voorhees, Lipman, and Brown), A., ii, 317.
experiments with ammonium salts on (Ehrenberg), A., ii, 1068.
action of calcium cyanamide on different kinds of (Rémy), A., ii, 220.
effect of carbon disulphide on (Egorow), A., ii, 421.
are, containing less than 0·02% SO₃ benefited by special manuring with sulphates? (Daikuvara), A., ii, 128.
fixation of nitrogen in, by free bacteria and its importance for the nutrition of plants (Koch, Litzen Doff, Krull and Alves), A., ii, 56.
constituent, organic, isolation and toxic properties of (Schreiner and Shorey), A., ii, 421.
microbiochemical formation of ammonia in (Perotti), A., ii, 124.
apparatus for showing the ammonia-condensation power of (Rössing), A., ii, 620.
isolation of dihydroxystearic acid from (Schreiner and Shorey), A., ii, 1067.
ammoniacal nitrogen in (Ehrenberg), A., ii, 60.
some properties of the organic matter in (Konig, Hasenbauer, and Grossmann), A., ii, 888.
ammonia-soluble phosphoric acid of (Frap), A., ii, 622.
amount of phosphoric acid in, relation between the, and the increased yield due to phosphatic manure (Pilz), A., ii, 423.
isolation of picolincarboxylic acid from, and its relation to soil fertility (Schreiner and Shorey), A., ii, 889.
acid, nitrification in (Hall, Miller, and Gimingham), A., ii, 524.
arable, ten years' experiments on denitrification in (Ampola), A., ii, 525.
black, nitrification in (Sasanoff), A., ii, 614.
clay, protective action of colloids on (Keppeler and Spangenberg), A., ii, 60.
humous carbonates, and their conversion into grey sand soils (Lebedeff), A., ii, 220.

Soil of the northern portion of the Great Plains region, estimation of nitrogen and humus in (Alway and Trumbull), A., ii, 1067.
paddy, behaviour of nitrates in (Daikuvara and Imaseki), A., ii, 127.
Roman, presence of thorium in (Blanc), A., ii, 248, 452.
poor sandy, why are, often easily injured by liming? (Yokoyama), A., ii, 621.
analyses, comparative investigation of the results of chemical, and of cultivation experiments (Opitz), A., ii, 421.
a method of, for investigations in plant physiology (Mitschler), A., ii, 428.
improved method for estimating the acidity of (Süchting), A., ii, 231 ;
(van Schermbeck), A., ii, 743, 994 ;
(Tacke and Süchting), A., ii, 994.
biological method for estimating alkali carbonates in (Christensen), A., ii, 67.
estimation of alkaline earths in (Foerster), A., ii, 1072.
use of nitron for estimating nitrates in (Litzen Doff), A., ii, 130.
colorimetric estimation of nitrogen in (Chouchak and Pouget), A., ii, 223.
estimation of phosphoric acid as phosphomolybdc acid in (Christensen), A., ii, 895 ; (Raben), A., ii, 896.
estimation of potassium in (Schenke), A., ii, 321 ; (Ronnet), A., ii, 534.
application of the cobaltinitrite method to the estimation of potassium in (Drushe), A., ii, 735.
See also Manurial experiments and Plants.

Soil bacteria. See under Bacteria.
Soil moisture, apparatus for measurement of the osmotic pressure of the (Konig, Hasenbauer, and Grossmann), A., ii, 888.
Soja-bean oil (Kametaka), A., ii, 851.
Solamin from the seeds and flowers of Solanum tuberosum (Colombo), A., ii, 99.
Solanum Dulcamarum, fruit of (Wells and Reeder), A., ii, 58.
Soldiers, composition and energy value of the food of (Pembrey and Parker), A., ii, 306.
Solid state, the (Kurkatoff), A., ii, 650.
Solid substances, velocity of absorption of gaseous substances by (Hantzsch and Wiegner), A., ii, 158.
INDEX OF SUBJECTS.

Solidification of inorganic salts and salt mixtures (PLATO), A., ii, 758.

Solubilities in mixed solvents (HERZ and KUHN), A., ii, 569.

Solubility, influences of (KERNOT, D'ACOSTINO, and PELLEGRINO), A., ii, 568.

Solubility product, the (STIEGLITZ), A., ii, 673.

Soluble substances, action of insoluble substances on (OECHSNER DE CONINCK and ARZALIER), A., ii, 843.

Solute, volatile, vapour pressure and osmotic pressure of a (CALLENDAR), A., ii, 1019.

Solution in a dissolved solid (PARSONS), A., ii, 89.

time taken by substance in dissolving (GAUILLARD), A., ii, 567.

Solutions, theory of (SCARPA), A., ii, 473; (CALLENDAR), A., ii, 671; (IKEDA), A., ii, 932. refractive indices of (GETMAN and WILSON), A., ii, 1001.

viscosity of (FAWSETT), T., 1004; P., 121; (RANKEN and TAYLOR), A., ii, 87.

viscosity and conductivity of some aqueous (GREEN), T., 2023, 2049; P., 187.

viscosity, "negative," of aqueous (TAYLOR), A., ii, 818.

viscosity of dilute alcoholic (HIRATA), A., ii, 930.

studies of the processes operative in (ARMSTRONG), A., ii, 814; (ARMSTRONG and WHEELER), A., ii, 815; (ARMSTRONG and CROITHERS), A., ii, 816; (CALDWELL and WHYMPER), A., ii, 817.

in mixtures of alcohol and water (CUNO), A., ii, 160.

in methyl alcohol, methyl chloride, and ethyl ether, critical temperatures of (CENTNERSZWER), A., ii, 13.

of certain salts, conductivity and viscosity of, in water, methyl alcohol, ethyl alcohol, and acetone and in binary mixtures of these solvents (JONES and VEZAYE), A., ii, 250, 260.

aqueous, hydrolysis, hydrolylation, and hydration as determinants of the properties of (ARMSTRONG), A., ii, 514.

concentrated aqueous, boiling and freezing points of, and the question of the hydration of the solute (JOHNSTON), A., ii, 661.

Solvent power and dielectric constant (WALDEN), A., ii, 159.

Solvents, relation between the ionising power and the dielectric constants of (MCIVOR), A., ii, 657.

influence of, on the equilibrium constant (PISSARJEWSKY and LEVIT), A., ii, 570.

influence of, on the rotation of optically active compounds (PATTERSON and THOMSON), T., 355; (PATTERSON and MCDONALD), T., 936; P., 125; (PATTERSON), T., 1836; P., 216.

mixed, solubilities in (HERZ and KUHN), A., ii, 569.

organic, and their dissociative power (WALDEN), A., ii, 159.

supposed connexion between dielectric constant and isomerising power of, in keto-enol desmotropy (MICHAEL and HIBBERT), A., ii, 455.

SORAJNIDIOI and its diacetyl derivative (OSTERLE and TISZA), A., ii, 527.

SORBIC acid and its polymeride (RIEDEL), A., i, 501.

L-SORBose, formation of, from L-gulose and L-idose (ALBERDA VAN EKENSTEIN and BLANKEMA), A., i, 136.

Sound, measurement of the velocity of, in liquids (DÖNSING), A., ii, 153.

Sökhill extractor, modification of the (WOOD), A., ii, 424.

Spark discharge. See under Electrochemistry.

Spark spectra. See under Photochemistry.

Sparteine (MOURE and VALEUR), A., i, 43, 44, 103; (VALEUR), A., i, 736, 1006.

application of Hofmann's reaction to (MOURE and VALEUR), A., i, 43.

methiodides (MOURE and VALEUR), A., i, 563.

ISO-Sparteine and its derivatives (MOURE and VALEUR), A., i, 103.

constitution of (MOURE and VALEUR), A., i, 206.

transformation of, into α-methylsparteine (VALEUR), A., i, 736.

additive salts (MOURE and VALEUR), A., i, 44, 103.

Specific cohesion, heat of fusion, and molecular weight at the melting point (WALDEN), A., ii, 1014.

Specific heat. See under Thermochernistry.

Specific inductive capacity. See Dielectric constant under Electrochemistry.

Spectra. See under Photochemistry.
INDEX OF SUBJECTS.

Spectrophotometer and Spectroscopic apparatus and investigations. See under Photochemistry.

Sphaero-rotation (Rosenheim and Tella), A., ii, 879.

Spices, estimation of essential oils in (Reich), A., ii, 1075.

 Spirits, estimation of alcohol and extract in, by the refractometer (Rasse), A., ii, 738.

 Splanchnic nerve. See Nerve.

 Spleen, guanylic acid of the (Jones and Rowntree), A., i, 487.

 Spleen glands. See Glands.

 Spongostene and Spongostanol and its bromo- and bromoacetyl derivatives and chloride from Suberites domuncula (Henze), A., i, 418.

 Springs. See under Water.

 Squaleus aconthias, a globulin from the egg-yolk of (Alsberg and Clark), A., ii, 963.

 Stannic acids and chloride. See under Tin.

 Stannichlorides. See under Tin.

 Starch, properties of pure (Maquenne), A., i, 249.

 properties of, in relation to its colloidal condition (Fouard), A., i, 503.

 colloidal properties of, and the unity of its constitution (Fouard), A., i, 138, 953.

 influence of the alternating current on the rate of hydrolysis of, by diastase and mineral acids (Ledebeff), A., i, 321.

 action of formaldehyde on (Reichard), A., i, 606.

 serum inhibiting the action of malt-extract on (Gessard and Wolff), A., i, 579.

 action of nitric acid on (Doroschewsky, Rakowsky, and Bardy), A., i, 767.

 transformation of, in plants (Buitkewitsch), A., ii, 723.

 iodide of. See Iodide of starch.

 evaluation of commercial (Parow and Neumann), A., i, 543.

 estimation of, polarimetrically (Lintner), A., ii, 1077.

 estimation of, polarimetrically, in cereals, &c. (Ewers), A., ii, 543.

 rice, detection of, in wheat flour (Peltrisor), A., ii, 236.

 Starch grains, composition of (Gatin-Gružewska; Maquenne), A., i, 320.

 Stars, presence of sulphur in some of the hotter (Lockyer), A., ii, 173.

 Starvation metabolism. See Metabolism.

 Steam, condition of (Bose), A., ii, 577.

 Steam distillation. See Distillation.

 Stearic acid, electrolytic reduction of oleic acid to (Marie), A., i, 244.

 solubility of, in ethyl alcohol at 0° (Emerson), A., ii, 236.

 Stearic acid, a-amino-, derivatives of (Fischer and Koppel), A., i, 773.

dibromo-, glyceride of (Neuberg and Rosenben; Lewkowitsch), A., i, 116.

 hydroxy- (Molinari and Fenaroli), A., i, 849; (Molinari and Barosi), A., i, 850.

 dihydroxy-, isolation of, from soils (Schreyer and Shokey), A., ii, 1067.

 iodo-, ethyl ester (Farbenfabriken vorm. F. Bayer & Co.), A., i, 310.

 Stearmanilide, p-amino- and p-nitro- (Sulzberger), A., i, 226.

 p-amino-, reaction of, with diazo-salts (Sulzberger), A., i, 483.

 Stearohydroxamic acid (Morelli), A., i, 768.

 Steel. See under Iron.

 Steels. See under Iron and Nickel steel.

 Steel process, Thomas basic. See under Iron.

 Stephanite crystals from Arizpe, Sonora, Mexico (Ford), A., ii, 505.

 Stereochemistry, origins of (Paternò), A., ii, 77; (Ulamician), A., ii, 137.

 Stereosymmetric compounds, relation between dielectric constant and chemical constitution of (Stewart), T., 1059; P., 124.

 Stereosomerism and the law of entropy (Michael), A., ii, 137.

 of compounds containing asymmetric carbon and asymmetric quinque-valent nitrogen atoms (Scholtz), A., i, 678.

 Sterigmatocystis nigra. See Aspergillus niger.

 Sterilisation, need for the testing of glass before (Gruhler), A., i, 204.

 "Stickstoffkalk." See Manurial experiments.

 4-Stilbazole, 2'-amino-, and its additive salts, and dyes from its diazo-salts, and 2'-nitro-, and its additive salts (Löwensohn), A., i, 51.

 Stilbene, cis-diamino-, picate and diformyl derivative of (Fischer and Prause), A., i, 220.

 2:4:2':4'-tetra-amino- and -nitro- (Green and Baddiley), T., 1725; P., 202.

Stilbene-4-carboxylic acid, 2-amino- and 2-nitro- (Ullmann and Gschwind), A., i, 623.

Stilbenedicarboxylic acid, nitration of (Heller and Leyden), A., i, 216.

Stilbene-2:2'-dicarboxylic acid, 4:4'-dinitro-, and its sodium salt (Green and Baddiley), T., 1724; P., 202.

Stilbenedicarboxylic anhydride 3:3'-diamino- and 3:3'-dinitro- (Heller), A., i, 217.

Stilbene group, colouring matters of the (Green and Baddiley), T., 1721; P., 201.

Stilbene series (Ullmann and Gschwind), A., i, 622.

Stilbene-4-sulphonamide, 2-amino-, and its acetyl derivative, and 2-nitro- (Ullmann and Gschwind), A., i, 623.

Stilbene-2-sulphonanilide, 4-nitro- (Ullmann and Gschwind), A., i, 623.

Stilbene from Montresta, Sardinia (Pela
cani), A., ii, 864.

Stirrer, circulation, for liquids (Goetze), A., ii, 681.

Stirring: relation between the velocity of, and the velocity of reaction in non-homogeneous systems (Jabłczynski), A., ii, 1020.

Stoichiometric laws, deduction of the (De Vries), A., ii, 366; (Baur), A., ii, 573; (Wald), A., ii, 681.

are the, intelligible without the atomic hypothesis? (Kuhn), A., ii, 98, 826; (Wald), A., ii, 367.

Stomach contents, peptolytic ferment enzymes in the (Aberdalden and Medigrecaan), A., ii, 1049.

detection of free hydrochloric acid in the (Steenstra), A., ii, 318.

Stopcocks, porous materials as substitutes for, in the manipulation of gases (Stock), A., ii, 99.

Strain theory, v. Baeyer's, thermal-chemical evidence for (Redgrove), A., ii, 758.

Strontia. See Strontium oxide.

Strontium, influence of, on the growth and composition of bone (Stoeltzenor), A., ii, 769.

Strontium salts free from barium, preparation of (Caron and Raquet), A., ii, 496.

Strontium chloride, physiological action of (Burgass), A., ii, 405.

ammonium chromate (Gröger), A., ii, 690.

nitrite, molecular volumes of (Rây), P., 240.

oxide (strontia), anhydrous, heat of formation of (De Forcrand), A., ii, 155.

hydrates of (De Forcrand), A., ii, 764.

silicide, preparation of (Goldschmidt), A., ii, 1037.

Strontium, quantitative separation of, from barium (Kahan), A., ii, 138.

Strophanthin and Munchi arrow poison (Mines), A., ii, 522.

Strophanthus and digitalis, action of, on the heart (Tigerstedt), A., ii, 612.

Strüverite and its relation to ilmenorutilite (Prior and Zambonini), A., ii, 398.

Strychnine, new method of oxidising (Leuchs), A., i, 563.

physiological action of (Sano), A., ii, 974.

behaviour of the brain towards (Sano), A., ii, 974.

action of, on the nerve fibres of the vagus of the heart (Forli), A., ii, 721.

effect of, on muscular work (Varrier-Jones), A., ii, 313.

the supposed antidotes to (Dorlencourt), A., ii, 721.

so-called antitoxic power of animal tissues towards (Pellacani and Forli), A., ii, 1062.

iodine derivatives of (Buraczewski and Koźniewski), A., i, 1007.

Strychninonic acid (Leuchs), A., i, 564.

Strychnos aculeata, active principles of the fruit of an African (Hébert), A., ii, 317.

Strychnos alkaloids (Leuchs), A., i, 563.

Sturgeon, Caspian, protamine from the spermatozoa of the (Malenück), A., i, 1039.

Styphnic acid, molecular compounds of (Gibson), T., 2098; P., 241.

Styracitoll from the fruit of Styrax Obassia (Asahina), A., ii, 59.

Styrene, formation of, from cinnamic acid by means of moulds (Herzog and Ripke), A., ii, 1064.
SUBSTANCE, **C₂H₅O₂N**, from ethyl iodomethylpipеридиламинокетон ([V. BRAUN]), A., i, 608.

**C₂H₆O₃** from acetylene and ethylene (LOSANITSCH), A., ii, 33.

**C₂H₆S₂** from acetylene and hydrogen sulphone (LOSANITSCH), A., ii, 33.

**C₂H₆O₅** (two), from 3-hydroxy-1:2-dihydroquinoxaline (MOTYLEWSKI), A., i, 370.

**C₆H₆N₂** from the decomposition of the silver salt of phenylmalonitrile (HESSELLER), A., i, 182.

**C₆H₈O₃** from acetylene and carbon monoxide (LOSANITSCH), A., ii, 33.

**C₆H₈S₁₀** from carbon disulphide and ethylene (LOSANITSCH), A., ii, 32.

**C₂H₆O₃** polymeride of, from the action of the silent electric discharge on moist methane (LOF), A., i, 117.

**C₆H₈O₅** from isatin and hydrogen cyanide (HELLER and NÖTZEL), A., i, 267.

**C₆H₈O₅N₂** from dicyanodiamide and benzocyanohydride (POHL), A., i, 576.

**C₆H₁₂OCl**, from sabina ketone and hydrogen chloride (WALLACH and HEYER), A., i, 425.

**C₆H₁₂O₃** from the reduction of 4:7-dimethylcoumarin (FRIES and PICKEWIRTH), A., i, 824.

**C₁₀H₁₃O₂** from the condensation of acetaldehyde (ZEISEL and V. BITTÖ), A., i, 761.

**C₁₀H₁₃S₄** from acetylene and hydrogen sulphone (LOSANITSCH), A., ii, 33.

**C₁₀H₁₅O₂**, from the Californian laurel (TUTIN), T., 257; P., 24.

**C₁₀H₁₅O₂** from ethylene and carbon monoxide (LOSANITSCH), A., ii, 33.

**C₁₀H₁₅O₄Cl₄** from the action of thionyl chloride on isosafrole dibromide (BAVER and EWIN), T., 2909.

**C₁₀H₁₅O₃I** from the action of Wys's solution on 8-napthol (WAKE and INGLE), A., i, 416.

**C₁₀H₁₅O₃N** from the action of hydrochloric acid on ethyl ammonium 6-hydroxy-2-methylpyridine-3:5-di-carboxylate (SIMONSEN), T., 1029.

**C₁₀H₁₅OBr** from the acid, **C₁₀H₁₅O₂Br** from pinene (HENDERSON and HEILBRON), T., 291; P., 31.

**C₁₀H₁₅OCl** from pinene (HENDERSON and HEILBRON), T., 294; P., 31.

**C₁₀H₁₅O₂N₂** from silver permitsocamphor (ANGELI and MARCHETTI), A., ii, 842.

**C₁₀H₁₅O₂N₂** from the action of ethyl chloroacetate on hydrazine dithiocarbamate (ANDREASCH), A., i, 684.
**INDEX OF SUBJECTS.**

**Substance,** $C_{11}H_{20}O_{2}N_2$ (two), from the hydrolysis of casein (SKRAUP), A., i, 931.

$C_{12}H_{20}O_3$, from ethyl oxalate and ethyl bromodihydracetate (RASSOW and BAUER), A., i, 316.

$C_{12}H_{20}S_2$, from ethylene and hydrogen sulphide (LOSANTISCH), A., ii, 35.

$C_{12}H_{20}O_2N_2$, from the hydrolysis of casein (SKRAUP), A., i, 931.

$C_{13}H_{24}O_5N_2$ (two), from the oxidation of tetramethylhydrobrazileinol (ENGEES, PERKIN, and ROBINSON), T., 1146.

$C_{13}H_{16}O_6$, from the oxidation of tetramethylhydrobrazileinol (ENGEES, PERKIN, and ROBINSON), T., 1145.

$C_{13}H_{14}O_4N_4$, from 2:2-dimethylindole (ANGELI and MARCHETTI), A., i, 207.

$C_{14}H_{22}O_2$, from its copper salt, from the condensation of aminopenicillenic acid and glycine (GODDEN), T., 1172.

$C_{14}H_{18}O_2N_2$, from the action of propylamine on ethyl vinyl ketone (BLAISE and MAIRE), A., i, 399.

$C_{14}H_8O$, from 9-methylfluorene alcohol (DAUFRESNE), A., i, 165.

$C_{14}H_{12}O_2$, and its acetyl derivative, from Grindelia resin (POWER and TUTIN), A., ii, 526.

$C_{14}H_{16}N_6$, from the action of magnesium phenyl bromide on bistriaethanol (FORSTER, FIERZ, and JOSHUA), T., 1072; P., 102.

$C_{14}H_{10}O$, from $\psi$-euphorbene (TSCHIRCH and LEUCHTENBERGER), A., i, 196.

$C_{14}H_{12}ON_2$, and its benzoate and acetate and methyl derivative, from $\alpha$-phenylbenzylhydrazine and carbamido (MILRATH), A., i, 581.

$C_{14}H_{12}O_2$, from aloe-emodin (HESSE), A., i, 439.

$C_{14}H_{12}O_3$, from the action of benzaldehyde on magnesium and ethyl $\alpha$-bromoisobutyrate (ZEITNER), A., i, 244.

$C_{14}H_{13}Cl_8$ (or $C_{14}H_{12}Cl_8$), from cadinene (DEUSSEN and LEWINSOHN), A., i, 354.

$C_{15}H_{20}O_2$, from caryophyllene (DEUSSEN and LEWINSOHN), A., i, 354.

$C_{16}H_{22}Br_6$, from cadinene (DEUSSEN and LEWINSOHN), A., i, 354.

$C_{15}H_{12}O_2N_2$, from the action of ethyl pyruvate on $p$-toluidine (SIMON), A., i, 738.

$C_{16}H_{12}O_3$, from the root-bark of *Morinda citrifolia* (OSTERLE and TISZA), A., ii, 527.

**Substance,** $C_{15}H_{16}O_2$, from the action of sodium ethoxide on phenylethylene glycol methyl ether (TIFFENEAU), A., i, 19.

$C_{16}H_{20}O_3$, from the condensation of methyl 2:4-dimethoxybenzoylpropionate with ethyl oxalate (PERKIN and ROBINSON), T., 507.

$C_{16}H_{12}O_2$, from the substance, $C_{16}H_{10}O_2N_4$ (HELLER and SOURLIS), A., i, 208.

$C_{16}H_{14}O_2$, from 8-thiocyanouquione and aniline (EDINGER), A., i, 384.

$C_{16}H_{10}O_2N_4$, and its reactions (HELLER and SOURLIS), A., i, 208.

$C_{17}H_{18}O_2N_2$, from the interaction of $p$-nitrobenzyl chloride and isonitrosocamphor (FORSTER and HOLMES), T., 248; P., 8.

$C_{17}H_{20}O_2N_2$, (m.p. 114°), from the interaction of $p$-nitrobenzyl bromide and isonitrosocamphor (FORSTER and HOLMES), T., 250; P., 9.

$C_{17}H_{20}O_2N_2$, (m.p. 175°), from the interaction of $p$-nitrobenzyl chloride and isonitrosocamphor (FORSTER and HOLMES), T., 248; P., 8.

$C_{18}H_{16}O$, from the action of magnesium ethyl bromide on anthraquinone (CLARKE), A., i, 331.

$C_{19}H_{10}S$, from the action of sulphur on resin oil (SCHULTZE), A., i, 356.

$C_{19}H_{18}O_2N_4$, from methylanilinoacetonitrite and cyanogen bromide (V. BRAUN), A., i, 625.

$C_{19}H_{20}O_3$, from the expressed oil of nutmeg (POWER and SALWAY), T., 1655; P., 198.

$C_{19}H_{20}O_3$, from $\psi$-euphorbene (TSCHIRCH and LEUCHTENBERGER), A., i, 196.

$C_{19}H_{14}O_2N_4$ from $\beta$-naphthol and 2:3:5-trinitro-4-acetylaminnophenol (MELDOLA and HAY), P., 211.

$C_{19}H_{20}Cl_3$, from the compound, $C_{4}H_{10}OCl$, and hydrogen chloride (WALLACH and HEYS), A., i, 425.

$C_{19}H_{16}O_4NCl$, from nickel on carbazole (PADOA and CHIATES), A., i, 105.

$C_{19}H_{20}O_2N_2$ from the action of ethyl pyruvate on $p$-toluidine (SIMON), A., i, 738.

$C_{19}H_{16}O_2N$, from the action of ozone on thelaine (RIIDDEL), A., i, 106.

$C_{19}H_{20}O_2N_2$, from the action of pyruvic acid on $p$-toluidine (SIMON), A., i, 687.

$C_{19}H_{20}O_2N_3$, from the decomposition of oleic acid azonide (MOLINARI and BARONI), A., i, 850.
Substance, $C_{20}H_{14}N_2$, from 2-methylindole, ethyl acetate, and sodium ethoxide (Angeli and Marchetti), A., i, 203.

$C_{29}H_{32}O_4$ and its acetyl, methyl, and benzoyl derivatives, from papa-verinium methiodido (Decker and Dunant), A., i, 206.

$C_{29}H_{32}O_4$, from ethylaminoacetanilide and cyanogen bromide (V. Braun), A., i, 225.

$C_{29}H_{32}O_4$, from 2-hydroxy-4-methylphenylidimethylcarbinol (Fries and Fickewirth), A., i, 824.

$C_{28}H_{30}O_4$, from the alkaloid, $C_{45}H_{47}O_4$, from Chinese Corydalis tubers (Makoshi), A., i, 825.

$C_{28}H_{30}O_4$, from quinoline and methyl salicylate (Spady), A., i, 915.

$C_{28}H_{30}O_4$, from quinine (Wolffenstein and Wolff), A., i, 283.

$C_{29}H_{32}O_4$, and its trinitro-derivative, from the action of copper powder on indazole (Jacobson and Hüber), A., i, 299.

$C_{29}H_{30}O_4$, from $\alpha \beta \gamma \gamma$-tetracyclicbutyrolactone (Reimer and Reynoldis), A., i, 989.

$C_{29}H_{30}O_4$, from 1-[2-5-dimethylhydrocoumarinyl]-2:5-dimethylhydrocoumarone (Fries and Klostermann), A., ii, 822.

$C_{29}H_{30}O_4$, from Simaruba amara (Gilling), A., ii, 527.

$C_{39}H_{36}O_4$, from methane, ethylene, and oxygen (Losanitsch), A., ii, 33.

$C_{29}H_{32}O_4$, from the absorption of oxygen by the condensation product of ethylene (Losanitsch), A., i, 846; ii, 83.

$C_{29}H_{32}O_4$, from the action of ethyl pyruvate on p-toluidine (Simon), A., i, 789.

$C_{29}H_{32}O_4$, from dinitrophenyl disulphide (Fromm and Wittmann), A., ii, 632.

$C_{25}H_{30}O_3$, from ethyl phenylpropionate, acethophenone, and sodium ethoxide (Ruhemann), T., 436; P., 52.

$C_{25}H_{30}O_3$, from the action of ethyl oxalacetate on benzylidene-$\beta$-naphthylamine (Simon and Mauguin), A., i, 296.

$C_{25}H_{30}O_3$, from rongalite, aniline hydrochloride, and formaldehyde (Binz and Isaac), A., i, 941.

$C_{25}H_{30}O_3$, from benzyl cyanide, sodium methoxide, and ethyl cyanamate (Avery and McDole), A., i, 344.

Substance, $C_{26}H_{30}O_3N_5$, and its copper salt, from the condensation of aspartic acid and aminopinecarboxylic acid (Godden), T., 1173.

$C_{26}H_{44}O_3$, and its acyl derivatives, from the oxidation of cholesterol (Pickard and Yates), T., 1680; P., 121.

$C_{27}H_{30}O_4N_2$, from rongalite and aniline hydrochloride (Binz and Isaac), A., i, 941.

$C_{27}H_{30}O_4N_2$, and its bromo-derivatives, from the condensation of acetylene (Jovitschitsch), A., i, 118.

$C_{27}H_{30}O_4$, and its acetyl from the condensation of ethylene, and the action of bromine on it (Jovitschitsch), A., i, 118.

$C_{27}H_{30}O_4$, and its acetate from the latent from Euphorbia (Cohen), A., i, 884.

$C_{27}H_{30}O_4N_2$, from the action of fuming nitric acid on the substance, $C_{26}H_{30}O_3$ (Jovitschitsch), A., i, 118.

$C_{27}H_{30}O_4S$, and $C_{26}H_{30}O_4S$, from thioduplobenzylidenacetophenone (Fromm and Lambrecht), A., i, 990.

$C_{27}H_{30}O_4S$, from the action of bromine on thioduplobenzylidenacetophenone (Fromm and Lambrecht), A., i, 990.

$C_{27}H_{30}O_4S$, from the reduction of dibenzylidithiolinedisulphonic acid (Gnehm and Schönholzer), A., i, 113.

$C_{25}H_{44}O_3$ (or $C_{25}H_{43}O_2$) from the latex from Euphorbia (Cohen), A., i, 884.

$C_{25}H_{44}O_7$ from olive leaves (Power and Tutin), T., 898; P., 117.

$C_{25}H_{47}O_7$, from the reduction of geraniol (Enklaar), A., i, 664.

$C_{29}H_{44}O_4$, from $\beta$-methylanthraquinone (Badische Anilin & Soda-Fabrik), A., i, 999.

$C_{29}H_{32}O_4$, from the oxidation of the lactone of diphenyl-2-hydroxy-9-phenylanthranolactic acid (V. Liebig and Keim), A., i, 449.

$C_{29}H_{32}O_4$ from diphenylketonquinolined and anthraquinone (Staudinger), A., i, 411.

$C_{29}H_{32}O_4$, from acetylene and oxygen (Losanitsch), A., ii, 32.

$C_{29}H_{32}O_4$, from the action of aniline on o-benzoylbenzoic acid (Meyer), A., i, 25.

$C_{29}H_{32}O_4$, from the hydrolysis of methyl o-methoxytritanate (V. Liebig and Keim), A., i, 449.

$C_{29}H_{32}O_4$, from ethyl oxalacetate and benzylidene-$\beta$-naphthylamine (Simon and Mauguin), A., i, 296.
Substance, \(C_{46}H_{34}N_4\), from bisanhydrophenacylamine (Gabriel and Lieck), A., i, 465.

\(C_{46}H_{34}\), from acetylene (Losanitsch), A., ii, 33.

\(C_{46}H_{34}N_9\), from the hydrolysis of anilinoacetal (Wohl and Lange), A., i, 17.

\(C_{46}H_{34}O_5\), from acetylene (Losanitsch), A., ii, 33.

\(C_{46}H_{34}O_5\), and its diacetate, from the oxidation of dicholesteryl ether (Pickard and Yates), T., 1882; P., 121.

\(C_{46}H_{34}O_5N_3\), from aniline and benzoic acid (v. Liebig), A., i, 646.

\(C_{46}H_{34}O_5N_3\), and \(C_{46}H_{34}O_5N_3\), from \(O\)-toluidine and benzoic acid (v. Liebig), A., i, 646.

Substitution of alkylxy-groups in the benzene nucleus by hydrogen (Semmler), A., i, 557.

of hydroxyl-groups by hydrazino-groups (Franzen and Eichler), A., i, 831.

of the sulphonic group by the cyano- and carboxyl-groups in azo-compounds (Lange), A., i, 300.

Succinamic acid, ethyl ester (Mol), A., i, 77.

Succindialdehyde, molecular dispersion of (Harries), A., i, 317.

unimolecular (Harries and Hohenemser), A., i, 133.

Succinlein, \(C_{16}H_{10}O_5\), and its acetate, from succinimide and quinol (Meyer and Witte), A., i, 671.

Succinic acid, production of, during alcoholic fermentation (Ehrlich), A., ii, 416.

method of estimating, in fermented liquids containing other fixed and volatile acids (Pozzi-Escot), A., ii, 993.

Succinic acid, alkaloidal salts, and their optical activity (Hilditch), T., 704; P., 61.

aluminium salt, occurrence of, in proteaceous trees (Smith), A., ii, 855.

ammonium ethyl ester-salt (Mol), A., i, 77.

Succinic acid, cetyl and \(O\)- and \(p\)-nitrobenzyl esters (Meyer and Marx), A., i, 602.

ethyl ester, influence of certain sulphates on the formation of (Pheles, Palmer, and Smillie), A., i, 790.

Succinic acid, amino-.. See Aspartic acid. dibromo-, benzyl and cetyl esters (Meyer and Marx), A., i, 602.

Succinic acid, \(d\)ioximino-, ethyl ester, action of nitric acid on (Wahl), A., i, 141.

Succinic acids, aromatic, synthesis of some (Avery and Upson), A., i, 343.

Succinimide hydrogen peroxide (Tanatar), A., i, 400.

4-Succiniminophthalic acid, methyl ester (Bogert and Renshaw), A., i, 652.

Succinophenone, dibromo-, action of phenylhydrazine and of \(a\)-phenylbenzylhydrazine on (Meyer and Marx), A., i, 602.

Succinyl chloride, tautomerism of (Meyer and Marx), A., i, 602.

Succinylcresotic acids, \(\alpha\), \(m\), and \(p\) (Farbenfabriken vorm. F. Bayer & Co.), A., i, 798.

Succinylisalicylic acid and its methyl homologues, preparation of (Farbenfabriken vorm. F. Bayer & Co.), A., i, 798.

Sucroclasm. See Sugars, fission of.

Sucrose (cane sugar, saccharose), conductivity and viscosity of solutions of (Green), T., 2023; P., 187.

and lithium chloride, conductivity and viscosity of mixtures of solutions of (Green), T., 2049; P., 187.

solutions, osmotic pressure of, at 10° (H. N. and H. V. Morse), A., ii, 671.

osmotic pressure of, at 15° (Morse and Mears), A., ii, 1019.

density of (Fouquet), A., i, 855.

density of aqueous solutions of (Fouquet), A., i, 855.

inversion of (Osaka), A., i, 856.

theory of the inversion of (Meyer), A., ii, 265.

inversion of, by invertase (Hudson), A., i, 605, 856; (Acree), A., ii, 1022.

and other substances (salts and non-electrolytes), changes effected by the reciprocal interference of (Caldwell and Whymer), A., ii, 817.

the storage and transportation of, in the best (Strommer), A., ii, 728.

detection of (Pozzi-Escot), A., ii, 740.

polarimetric determination of (Watts and Tempany), A., ii, 236.

normal tubes for the polarimetric estimation of (Rouset), A., ii, 73; (Pellet), A., ii, 235.

and invert sugar, estimation of, in mixtures (Ling and Rendle), A., ii, 642.

Sugar in blood (Rona and Michaelis), A., ii, 117; (Michaelis and Rona), A., ii, 329.
Sugar, total amount of, in blood (Lépine and Boullon), A., ii, 357.

of blood, behaviour of, after bleeding (Andersson), A., ii, 767.
apparatus for polarising, at 87° (Sy), A., ii, 1076.
excretion of, in healthy men (Schöndorff), A., ii, 311.
action of various chemical substances on the excretion of (Baer and Blum), A., ii, 122.
estimation of (Jessen-Hansen), A., ii, 638; (Bang), A., ii, 739.
estimation of, by Allihn’s and Meissl’s methods (Schaumann), A., ii, 437.
estimation of, in blood (Bang), A., ii, 235.
estimation of small quantities of, in urine (Schöndorff), A., ii, 311.
Sugar from morindin and its phenylbenzylhydrzone and phenyllosazone (Oesterle and Tisza), A., i, 37.

Sugar, invert, and sucrose, estimation of, in mixtures (Ling and Rendle), A., ii, 542.
influence of clarification with lead acetate on the estimation of (Schrefeld), A., ii, 1076.

Sugar group, dissociation processes in the (Nef), A., i, 5; (Kilian), A., i, 128.

Sugar solutions, effect of clarification with basic lead acetate on the optical activity and copper reducing power of (Watts and Tempany), A., ii, 236.
formation of formaldehyde in (Ramsay), A., ii, 994.

Sugars (Blanksm and Alderba van Ekenstein), A., i, 951.

and their reduction and identification from glucosides (Alderba van Ekenstein and Blanksm), A., i, 9.
electrolysis of (Neuberg), A., i, 128.
fission of (sucroclasm) (Löb), A., i, 715, 764.
rate of oxidation of, in an acid medium (Bunzel), A., i, 135.
depolymerisation of (Neuberg), A., i, 765.
utilisation of, by the tissues (McGuigan), A., ii, 406.
the capacity of the liver to reverse the optical action of (Pflüger), A., ii, 307.
phenylhydrzones of (Reclaire), A., i, 1013.
precipitation of, by cupric hydroxide (Yoshimoto), A., i, 766.

Sugars and glucosides, application of biochemical methods for the detection of, in Taxee (LeFebvre), A., ii, 57.
colour and spectral reactions of, with naphtharesorcinol and hydrochloric acid (Tollens and Rorive), A., ii, 638.

value of the different methods for estimating, in urine (Funk), A., ii, 902.

Sugars, C₅, from meta- and parasaccharin (Kilian), A., i, 135.

Sugars, reducing, detection and identification of certain, by condensation with p-bromobenzylhydrzone (Kendall and Sherman), A., ii, 902.
estimation of (Zerban and Naquin), A., ii, 902.
volumetric estimation of (Ling and Jones), A., ii, 541; (Ling and Rendle), A., ii, 542.
volumetric estimation of, by Fehling’s solution (Watts and Tempany), A., ii, 487.
the reduction of cuprous oxide in the estimation of (Stanék), A., ii, 638.

Sugars. See also Carbohydrates.

Sulphanilic acid. See Aniline-p-sulphonic acid.

Sulphates. See under Sulphur.

Sulphides. See Metallic sulphides, Polysulphides, and under Sulphur.

Sulphination of phenolic ethers and the influence of substituents (Smiles and Le Rossignol), T., 745; P., 61.

Sulphines and sulphoxides (Hofmann and Ott), A., i, 84.

Sulphinic acids, preparation of (Knoevenagel and Kenner), A., i, 970.

and sulphonic acids, aromatic, alkaloidal salts, and their rotatory power (Hilditch), T., 1620; P., 195.

Sulphoacetic acid, chloro-, strychnine salts, and their optical activity (Pope and Read), T., 795; P., 99.

4-Sulpho-2-aminophenyl-p-toluenesulphonic acid, sodium salt (Cassella & Co.), A., i, 785.

4-p-Sulphobenzeneazo-1-dimethylaminothylamine and its sodium salt (Scharwin and Kaljanoff), A., i, 704.

4-p-Sulphobenzeneazo-m-phenylene-tetramethylidiamine and its alkali salts (Scharwin and Kaljanoff), A., i, 704.

m-Sulphobenzeneazosalicylic acid (Grandmougin and Guisan), A., i, 927.

Sulphobenzylethylisobutylosilicyl oxide, metallic, bornylamine, cinchonidine, cinchonidine hydrogen, and methylamine salts (Luff and Kipping), T., 2010; P., 224.
dL-Sulphobenzylethylisobutylysilicyl oxide, resolution of, and the properties of the optically active acids and their amine salts (Luff and Kippino), T., 2090; P., 258.
dL-Sulphobenzylethylpropylsilicyl oxide, decomposition and resolution of (Kippino), T., 462; P., 47.
Sulphobenzylethylpropylsilicyl oxides, optically active, and their metallic, amine, and alkaloidal salts (Kippino), T., 457; P., 47.
Sulphobenzylethylsilicone and its salts (Robison and Kippino), T., 445; P., 25.
a-Sulphobutyric acid, y-aminophenyl (Gabriel and Colman), A., i, 275.
2-Sulphodiphenylamine-2'-carboxylic acid, 4-aminophenyl (Ullmann), A., i, 457.
4-Sulphonamino-1-phenyl-2:3-dimethyl-5-pyrazolone, preparation of (Scheitlin), A., i, 688.
Sulphonation reaction, kinetics of the (Martinsen), A., ii, 572.
Sulphonic acids and sulphinic acids, aromatic, alkaloidal salts, and their rotatory power (Hilditch), T., 1620; P., 198.
Sulphonic group, replacement of, by the cyano- and carboxyl-groups in azo-compounds (Lange), A., i, 300.
Sulphonimides, aromatic, preparation of (Haga), A., i, 370; (Suzuki), A., i, 571.
4-Sulpho-2-nitrophenyl-p-toluenesulphonic acid, sodium salt (Casella & Co.), A., i, 785.
Sulphosalicylic acid, action of, on sodium diborate (Barthe), A., i, 271.
Sulpho-a-siliconaphthoic acid (Khotinovsky and Seregenkoff), A., i, 1032.
Sulphoesteric acid, formula of (Dubovitz), A., ii, 992.
6-Sulpho-n-tolnic acid, 2:4-dinitro-, and its salts (Karslake and Morgan), A., i, 410.
2-Sulpho-p-tolnic acid, preparation of, and its barium hydrogen salt (Melrum and Perkin), T., 1419.
Sulphoxides and sulphines (Hoffmann and Ott), A., i, 54.
preparation of (Gazzar and Smiles), T., 1833; P., 216.
preparation and constitution of (Hinsberg), A., i, 875.
Sulphoxylic acid, derivatives of (Fromm and Gaupp), A., i, 969.
Sulphur and its cyclic compounds (Erdmann), A., ii, 830.
presence of, in some of the hotter stars (Lockyer), A., ii, 173.
Sulphur, dynamic allotropy of (Kruyt), A., ii, 1028.
amorphous (Smith and Carson), A., ii, 32.
colloidal (Raffo), A., ii, 633.
bi-, quadri-, and sexa-valent, influence of, on rotatory power (Hilditch), T., 1618; P., 195.
gaseous dispersion of (Cuthbertson and Metcalf), A., ii, 545.
liquid, electrical conductivity of (Wigand), A., ii, 500.
changes in the viscosity of (Rotinjan), A., ii, 463.
statics and kinetics of the transition which occurs in (Wigand), A., ii, 676.
molten, chemistry of (Erdmann), A., ii, 832.
monoclinic, heat of fusion of (Wigand), A., ii, 676.
vapour pressure of, at low temperatures (Ruff and Graf), A., ii, 578.
variation of the surface tension of, with rise of temperature (Capelle), A., ii, 683.
boiling point of (Callendar), A., ii, 1029.
boiling point of, on the constant pressure air thermometer (Eumorfopoulos), A., ii, 1029.
foam structure (cellular structure) of, and its influence on double refraction, dichroism, electrical properties, and formation of crystals (Quincke), A., ii, 823.
spontaneous oxidation of (Pollacci), A., ii, 684.
reaction of calcium oxide with (Thatcher), A., ii, 380.
new type of combination of, with certain iodides (Auger), A., i, 241.
Sulphur compounds, chemistry of (Bloch), A., ii, 580.
with antimony and chlorine (Taverne), A., ii, 198.
with iodine, existence of (Smith and Carson), A., ii, 32; (Ephraim), A., ii, 581.
of the nervous system (Koch), A., ii, 52.
Thionyl chloride, action of, on aldehydes (Horrino and Baum), A., i, 528; (Schmidt), A., i, 654.
action of, on the methylene ethers of catechol derivatives (Barger), T., 569; P., 59; (Barger and Ewins), T., 735; P., 60.
Sulphuryl chloride equilibrium, thermodynamics of the (Trautz, Baich, and v. Deckend), A., ii 569.
Sulphur hydride. See Hydrogen sulphide.

Sulphides, spontaneous oxidation of (Pollacci), A., ii, 684.
of the elements of the second group, crystallography of (Beckenkamp), A., ii, 280.
aromatic, interaction of, with hydrogen dioxide (Gazzar and Smiles), T., 1833; P., 216.
selemites, and tellurides, aromatic, and their halogen additive compounds, melting and boiling points of (Lyons and Bush), A., i, 417.
mineral, estimation of sulphur in (Hassreider), A., ii, 893.
See also Metallic sulphides and Polysulphides.

Sulphur dioxide, physical properties of (Baume), A., ii, 372.
refractive index of gaseous (Cuthbertson and Metcalfe), A., ii, 545.
mechanism of the reaction of, with oxygen in presence of iron oxides (Keppeler, D'Ans, Sundell, and Kaiser), A., ii, 482.
action of, on plants (Wieler), A., ii, 887.
estimation of, in wines (Mensio), A., ii, 63.
trioxide, preparation of (Frank), A., ii, 684.
refractive index of gaseous (Cuthbertson and Metcalfe), A., ii, 545.

Sulphuric acid, preparation of (Bender), A., ii, 684.
absolute, preparation of, and condition of substances in (Hantzsch), A., ii, 14, 462; (Oddo and Scandola), A., ii, 353.
electrolytic properties of dilute solutions of (Whetham and Paine), A., ii, 802.
viscosity of fuming (Dunstan and Wilson), T., 2179; P., 270.
evaporation of water and solutions of (Vaillant), A., ii, 461.
influence of, in nitration (Kuglen), A., i, 768.
assay of highly concentrated (Buchwald), A., ii, 130.
estimation of, volumetrically (Cooksey), A., ii, 982.

Sulphates, natural, from Chile (Palache and Warren), A., ii, 1047.
origin and variations of, in beer (Muntz and Trillat), A., ii, 782.

Sulphur:—

Sulphates, new method for determining the tension of (Keppeler and D'Ans), A., ii, 289; (L. Wöhler, Plüdemann, and P. Wöhler), A., ii, 290, 581.
See also Metallic sulphates.

Persulphuric acid, production of hydrogen peroxide from (Consortium für Elektrochemische Industrie), A., ii, 1028.

organic, pseudomorphic of (Wolff-Meister and Wolff), A., i, 283.

Sulphurous acid in its biochemical relationship (Grünhut), A., ii, 721.
excretion of, in man after administration of sodium sulphite and sulphurous acid in combination with sodium salt (Franz and Sonntag), A., ii, 714.
estimation of, in gelatins and other foods (Padé), A., ii, 893.

Hyposulphites (Binz and Isaac), A., i, 940.
analysis of, and their compounds with formaldehyde (Greibes), A., ii, 741.
Thiosulphuric acid, acid energy of, and its decomposition (Muller), A., ii, 102.
behaviour of, and its use in volumetric analysis (Casolari), A., ii, 173.

Thiosulphates, kinetics and catalysis of the reaction between hydrogen peroxide and (Abel), A., ii, 26.
action of, on permanganate in alkaline solution (Kilian), A., ii, 982.

Trithionates of the alkali metals (Mackenzie and Marshall), T., 1726; P., 199.

Tetraethionates, action of carbonates on (Gutmann), A., ii, 173.
of the alkali metals (Mackenzie and Marshall), T., 1726; P., 199.

Sulphur, organic compounds of nitrogen, phosphorus, and, in vegetables (Stutzer), A., ii, 124.

Sulphur, detection of arsenic in (Brand), A., ii, 532.
use of sodium peroxide in the estimation of (Parr), A., ii, 628.
rapid estimation of, in coals (Komarovsky), A., ii, 892.
Sulphur, estimation of, in iron and steel (Jaboulay), A., ii, 223; (Raymond), A., ii, 628; (Orthey), A., ii, 731.

estimation of, in mineral sulphides (Hassreidt), A., ii, 893.

estimation of, in organic substances (Bay), A., ii, 319.

estimation of total, in urine (Schulz), A., ii, 129; (Österrider and Wolf), A., ii, 426; (Konschegg), A., ii, 628.

Sulphur anion and complex sulphur anions (Knox), A., ii, 830.

Sulphuric acid, See under Sulphur.

Sulphuric acid contact process (L. Wöhler, Plüdemann, and P. Wöhler), A., ii, 290, 581.

Sunlight. See under Photochemistry.

Superphosphates. See under Phosphorus.

Supertension. See under Electrochemistry.

Suprarenal, so-called fatty degeneration of the (White), A., ii, 983.

Suprarenal glands of the dog, the blood issuing from the (Young and Lehmann), A., ii, 767.

antagonistic action of adrenaline and choline of the (Loihmann), A., ii, 407.

Suprarena. See Adrenaline.

Surface concentration, experimental examination of Gibbs's theory of, regarded as the basis of adsorption, with an application to the theory of dyeing (Levis), A., ii, 357.

Surface tension, compressibility, and other properties, relation between (Richards and Mathews), A., ii, 158.

of dilute aqueous solutions (Heydweiler), A., ii, 356.

of liquids investigated by the method of jet vibration (Pedersen), A., ii, 158.

Swan spectrum. See under Photochemistry.

d-Sylvic acid (Schkateloff), A., i, 890.

Sylvic acids, α, β-, and γ- (Schkateloff), A., i, 816.

Symphyllorcarpos racemosus, pectins from the fruit of (Bridel), A., ii, 125.

Syntheses with the aid of monochloromethyl ether (Simonsen), T., 1777; P., 212.

by means of the carboxylic esters of cyclic ketones (Kötz, Biber, Hesse, and Schwarz), A., i, 24.

XCV. ii.

Syntheses with phenol derivatives containing a mobile nitro-group (Meldola and Hay), T., 1659; P., 197.

with sodium-alkyl compounds (Schorigk), A., i, 866, 881, 886.

See also Electro-syntheses under Electrochemistry.

Synthetisar (Jovitschitsch), A., i, 118.

Syphon pipette. See Pipette.

T.

d-Talitol, preparation and properties of crystallised (Bertrand and Brunau), A., i, 249.

d-Talose, isolation of (Blankma and Alberda van Ekenstein), A., i, 951.

Tannins, constitution of (Lloyd), A., i, 347.

estimation of, in white wines (Koebner), A., ii, 240.

Tannin-phenylmethane and -thymolmethane and its bromo-derivative (Hildebrandt), A., i, 185.

Tanning, new method of (Meunier and Seyeweitze), A., i, 586.

Tanning material, some oxides as (UPPO-CRAMER), A., i, 377.

Tanning processes, changes in (Herzog and Adler), A., ii, 262.

Tantalum compounds (Balke and Smith), A., ii, 1045.

Taramellite, a new silicate of barium and iron (Taconi), A., ii, 863.

Tarbutte from Rhodesia (Spencer), A., ii, 397.

Tarragon oil, constituents of (Dau-Fresne), A., i, 436.
INDEX OF SUBJECTS.

Tarragon oil, levorotatory component of (Daufresne and Flament), A., i, 558.

presence of p-methoxy-cinnamaldehyde in (Daufresne), A., i, 19; (Daufresne and Flament), A., i, 558.

d-Tartaric acid and sodium molybdate, formation of compounds in solutions of (Quinet), A., i, 713; (Grossmann), A., i, 854.

natural and added, in natural wines (Astruc and Mahoux), A., ii, 992.
estimation of, in presence of malic and succinic acids (Gowing-Scope), A., ii, 905.
estimation of, in argol and wine lees (Pozz-Escot), A., ii, 740.
estimation of, in wines by evaporation (Mestrezeat), A., ii, 1078.

Tartaric acid, antimonyl sodium salt (Plimmer), A., i, 129.

barium and calcium salts, decomposition of, by alkali chlorides (Cantoni and Jolkowsky), A., i, 128.
bismuth salt (Telle), A., i, 851.
calcium salt, fermentation of (Emmerling), A., ii, 772.

basic ferric salt (Rosenthaler and Siebeck), A., ii, 246.

Tartaric acid, ethyl ester, rotation of, in alphatic halogen derivatives (Patterson and Thomson), T., 355.

rotation of, in aromatic halogen derivatives (Patterson and McDonald), T., 936; P., 125.

rotation of, in aromatic nitro-derivatives (Patterson), T., 1836; P., 216.
methyl hydrogen ester, crystallography of (Tannhauser), A., i, 713.

tate's laws and the weight of a falling drop (Morgan and Stevenson), A., ii, 356; (Morgan and Higgins; Higgin), A., ii, 668.

Tautomerism (Rabe, Spence, and Ehrenstein), A., i, 530.

the enol-ketonic (Dunstan and Stubbs), T., 1919; P., 224.

Taxaceae, application of biochemical methods for the detection of glucosides and sugars in plants of the tribe (Lefebvre), A., ii, 57.

Tea leaves, composition of, at various stages of development (Sawamura), A., ii, 125.

Teeth, chemical investigations on (Gassmann), A., ii, 609.

Telluride ores, assay of (Borrowman), A., ii, 777.

Tellurides. See under Tellurium.

Tellurium, native, from Asia Minor (Cesaro), A., ii, 861.
atom weight of (Markwald), A., ii, 33; (Baker), A., ii, 483

is, a mixture of two elements? (Bettel), A., ii, 372.
homogeneity of (Lenher), A., ii, 483.

the ultimate rays of (De Gramont), A., ii, 645.

radioactive. See Radium F.
cryoscopic constant of (Pélabon), A., ii, 687.

action of various anhydrous chlorides on (Lenher and Hill), A., ii, 484.

Tellurium compounds with arsenic and bismuth (Pélabon), A., ii, 687.

Tellurium dioxide, action of various anhydrous chlorides on (Lenher and Hill), A., ii, 484.

Tellurides, selenides, and sulphides, aromatic, and their halogen additive compounds, melting and boiling points of (Lyons and Bush), A., i, 417.

Tellurium dioxide and its compound with ether (Cockedge), T., 2176; P., 269.

Tellurium, estimation of (Lenher and Homberger), A., ii, 426.

Teloidine and its additive salts (Pyman and Reynolds), T., 2080; P., 234.

Temperature. See under Thermochemistry.

Terbium chloride, nitrate, peroxide, and sulphate (Urbain and Jantsch), A., ii, 189.

Terephthalic anhydride (Bucher), A., i, 792.

Terpene, C_{10}H_{16}, from methyl dihydro-carveol xanthate (Tschugaeff), A., i, 94.

Terpene compounds, resolution of linkings by addition of water to (Walach), A., i, 429.
fatty, reduction of (Enklaar), A., i, 664.

Terpene and camphor series, investigations in the (Tschugaeff), A., i, 93.
Terpenes and ethereal oils (Wallach, Evans, Churchill, Mallison, Mendelsohn-Bartholdy, and Rentschler), A., i, 402; (Wallach and Heyer), A., i, 424; (Wallach), A., i, 425, 429, 813, 997; (Wallach and Vivck), A., i, 809; (Wallach, Heyer, and Meister), A., i, 811.

Terpenes, from the Philippines and essential oils (Bacon), A., i, 814, 815.

Terpenes and their chemistry to the benefit of (Henderson and Heilbron), T., 283; P., 31.

Terpenes, experiments on the synthesis of (Haworth and Perkin), T., 573; P., 64; (Fisher and Perkin), T., 1871, 1876; P., 228.

Terpenes, Flawitzky's (Kremers), A., i, 434.

Terpin, C_{10}H_{10}O_2, and its dibromide and dichloride, from sabina ketone (Wallach and Heyer), A., i, 813.

Terpin, some reactions of (Isnard), A., ii, 908.

Terpinene and its modifications (Wallach), A., i, 813.

Terpinene-4-ol, formation of, from sabi-ene hydrate (Wallach), A., i, 430.

a-Terpinole, homologue of, from ethyl-nopinol (Wallach), A., i, 431.

1-α-Terpinol and its nitroschloride and nitropiperidide, and its oxidation (Wallach), A., i, 431.

Terpinoleins, d- and l-, synthesis of (Fisher and Perkin), T., 1871; P., 228.

Terrya nucifera, oil of (Kametaka), A., i, 851.

Tertiary bases reaction, definition of the term (Weidekind and Haeussermann), A., i, 671.

Test-tube holder, new form of (Stoltenberg), A., ii, 1027.

Tetanus toxin, material in the brain which unites with (Takaki), A., ii, 521.

Tetra-acetoxy-p-xylene (Fichter and Weiss), A., i, 659.

Tetra-acetyl. See under the parent Substance.

Tetra-alkylammonium salts, viscosity of (Taylor and Moore), A., ii, 818.

p-Tetra-anisyltetrazen (Wieland), A., i, 1026.

Tetra-arylhazdrazines, decomposition of (Wieland), A., i, 1014.

aa55-Tetra-alkylbutan-α5-diol (Houben and Hahn), A., i, 540.

s-Tetraethyldiaminodimethylcarbamide (Einhorn), A., i, 611.

Tetraethylidiaminodimethyltartramide (Einhorn), A., i, 611.

Tetraethylammonium iodide, conductivity and viscosity of, in water, methyl alcohol, ethyl alcohol, and nitrobenzene, and in binary mixtures of these solvents (Jones and Vezezy), A., ii, 260.

solvent power and dielectric constant of (Walden), A., ii, 159.

Tetraethylhydrofuran (Houben and Hahn), A., i, 540.

Tetraethylthionine and its derivatives (Gnehm and Schindler), A., i, 110.

Tetrahydroacridine and its derivatives and 5-carboxylic acid and its salts (Borsche, Tiedtke, and Rottsie-fer), A., i, 682.

Tetrahydroaoleosol, tetrachloro-, and its acetyl derivative (Löser), A., i, 980.

Δ10-Tetrahydrobenzo-α- and -β-naphth- indoles (Borsche, Witte, and Botte), A., i, 366.

Tetrahydrocarbazole, derivatives of (Borsche, Witte, and Botte), A., i, 365.

cis-Tetrahydrocarvestrenediol, synthesis of (Fisher and Perkin), T., 1889.

Tetrahydrocolumbamine methyl ether (Feist), A., i, 102.

Tetrahydrodi-coumaric and -coumarins, α- and β- (Fries and Ficke- wirth), A., i, 823.

Tetrahydrod-4-6-dimethylcoumarins, α- and β- (Fries and Ficke-wirth), A., i, 824.

Tetrahydroflavanthrens, α- and β-, and their derivatives (Scholl and Holder- mann), A., i, 697.

Tetrahydrofuran (Bourguignon), A., i, 280.

Tetrahydrojateorrhizine (Feist), A., i, 103.

Tetrahydrojinalool (α5-dimethyloctaño-), synthesis of (Enklaar), A., i, 984.

Tetrahydropalmitma and its aurichlo-ride (Feist), A., i, 103.

Δ3-Tetrahydropyridine, 3-carboxylic acid of, and its additive salts, and 3-cyano- (Wohl and Losanitsch), A., i, 47.

Δ3-Tetrahydropyridine-3-aldehyde and its oxime and their hydrochlorides and 1-benzoyl and 1-nitrobenzoyl derivatives (Wohl and Losanitsch), A., i, 46.

Tetrahydroprone compounds (Petr- enko-Kritschenko and Demen-tev), A., i, 560.
Tetrahydroquinidine hydrogen tartrates, \(r^-, d^-, \) and \(l^-\) (Ladenburg and Herrmann), A., i, 364.

Tetra-2:4-di-hydroxytritanol, derivatives of (V. Liebig), A., i, 447.

2:3:4:5-Tetramethoxy-1-allylbenzene (Thoms), A., i, 902.

Tetramethoxynaphthaquione (Bentley and Weizmann), T., 437; P., 52.

2:3:4:5-Tetramethoxybenzoic acid (Thoms), A., i, 902.

Tetramethoxy-2-benzoylbenzoic (Clayton), A., i, 1152.

Tetramethoxy-2:6:3':4'-Tetramethoxy-4-tetramethylamino-aminobenzhydrol, Tetramethyl-2:4-diminoamino benzaldehyde (Engels, Perkin, and Robinson), T., 1152.

7:8:4:5'-Tetramethoxy-4:3-indenobenzopyranol (1:4) anhydroferrichloride (Engels, Perkin, and Robinson), T., 1152.

2:3:4:5'-Tetramethoxy-6-methylbenzoyl-acetophenone (Tambor), A., i, 350.

2:6:3:5'-Tetramethoxy-4-methylbenzoyl-acetophenone (Tambor), A., i, 350.

2:3:4:5-Tetramethoxy-6-methylbenzoyl-acetophenone, 2:2'-di-hydroxy-, (Engels, Perkin, and Robinson), T., 1161.

Tetramethyl-2:4-di-aminobenzaldehyde and its salts (Sachs and Appenzeller), A., i, 186.

Tetramethyldiaminobenzhydrol, constitution of the compounds of, with some methylene derivatives (Fosse), A., i, 567, 568.

Tetramethyldiaminobenzylidene-acetophenone, -cycanoacetic acid, ethyl ester, -hydrazine, -malononitrile, -nitrobenzyl cyanide, and -rhodanalic acid (Sachs and Appenzeller), A., i, 187.

4-Tetramethyl-2:4'-diaminobenzylidene-1-phenyl-3-methyl-5-pyrazolone (Sachs and Appenzeller), A., i, 187.

Tetramethyldiaminobenzylphenylsulphone (Binz and Isaac), A., i, 940.

Tetramethyldiaminodiphenylglycine-amide (Hinsberg), A., i, 453.

Tetramethyldiaminodiphenylmethane, constitution of the methylene derivatives of (Fosse), A., i, 568.

4:4'-Tetramethyldiaminodiphenylmethane dioxide and its derivatives (Bamberger and Rudolf), A., i, 1011.

4:4'-Tetramethyldiaminodiphenyl-cotolylmethane, 8- and 4-amino-, and their oxidation (Bielecki and Kolewiew), A., i, 698.

Tetramethyldiaminophenyl-ethylcarbinol and -hydroxy-trichloroethane (Sachs and Appenzeller), A., i, 187.

Tetramethyldiaminotriphenylmethane dioxide and its derivatives (Bamberger and Rudolf), A., i, 1012.

Tetramethylaminom UINTONMBr2, 8-d-:cyano-(v. Braun), A., i, 603.

Tetramethylbenzidine, 8-a-dicyano-(v. Braun), A., i, 625.

Tetramethyl bromo- and chloro-glucose (Irvine and Moodie), T., 105.

1:3:4:7-Tetramethylcarbazole and its picrate (Borsche, Witte, and Bothe), A., i, 367.

Tetramethylhydrobrazileinol and its oxidation (Engels, Perkin, and Robinson), T., 1138.

Tetramethylhydroximateinol (Engels, Perkin, and Robinson), T., 1142.

Tetramethylidinaphthanthracene. See Picene, alky1 derivative.

Tetramethylellagic acid, preparation and reactions of (Herzic and Polak), A., i, 547.

cycloTetramerthylene. See cycloButane.

Tetramethylenediamine. See Putrescine.

Tetramethylethyltriaminodiphenyl-naphthylcarbinol. See Victoria Blue R.

Tetramethylethylene oxide, relation of, to pinacolin (Delacre), A., i, 243.

Tetramethyl glucose, derivatives of (Irvine and Moodie), T., 95.

Tetramethy glucoseanilide and its attempted alkylation (Irvine and Moodie), T., 103.

Tetramethyl glucoseoxime and its alkylation (Irvine and Moodie), T., 100.

Tetramethyldiaermanein (Engels, Perkin, and Robinson), T., 1141.

1:1:4:4-Tetramethylcyclohexan-3-one, 4-dichloro. (Auwers and Hessenland), A., i, 551.

1:1:4:5:8-Tetramethynaphthalene, absorption spectra of (Homer and Purvis), T., 1321; P., 147.

\(\alpha\)-Tetramethyl-\(\alpha\)-octenoic acid (\(\alpha\)-dimethyl-\(\alpha\)-dihydrogeranic acid), \(\beta\)-hydroxy- (Tiffeneau), A., i, 500.

Tetramethyldisparternium dihydroxide (Moureu and Valeur), A., i, 43.

Thallium molybdenum thiocyanate (ROSENHEIM and GARFUNKEL), A., i, 614.

Thallium, electrolytic estimation of, and probable existence of a new oxide of (GALLO and CENNI), A., ii, 986.

quantitative separation of, from silver (SPENCER and LE PLA), T., 953; P., 75.

Thallium ion, subvalent, existence in aqueous solutions of a (DENHAM), T., 833; P., 76.

Thallium salts. See under Thallium.

Thallylaminoacetonitrile (V. BRAUN), A., i, 628.

Thea japonica, oil of. See Camellia oil.

Thebaine, constitution of (BUCHERER), A., i, 43.

action of ozone on (RIEDEL), A., i, 1006.

Theobromine and its additive salts (SCHMIDT and SCHWABE), A., i, 45.

Theophyllin, alkyl derivatives of (SCHWABE), A., i, 45.

Thermochemistry:

Thermochemistry, calculation of hydrocarbon equilibria (V. WARTENBERG), A., ii, 26, 676.

Thermochemical constants, calculation of (REDGROVE), A., ii, 463, 564, 812.

equivalence, and the thermochemistry of nitrogen (THOMLINSON), A., ii, 1016.

evidence of v. Baeyer's strain theory (REDGROVE), A., ii, 758.

Thermodynamic calculation of electromotive forces (HALLA), A., ii, 755.

Thermodynamics, outline of a new system of (LEWIS), A., ii, 16.

cells with fused electrolytes (LORENZ and FOX), A., ii, 656.

cells of liquid (HENDERSON), A., ii, 655.

cells with solid substances (LORENZ and KATAYAMA), A., ii, 249.

of non-homogeneous mixtures (BOSE and CLARK), A., ii, 84.

of salts containing water of crystallisation (SCHOTTKY), A., ii, 1016.

of the sulphuryl chloride equilibrium, \( \text{SO}_4 + \text{Cl}_2 \rightarrow \text{SO}_2 + \text{Cl}_2 \) (TRAUTZ, BALSCH, and v. DECHEND), A., ii, 569.

Heat contents of binary systems (TAMMANN), A., ii, 660.

Heat power, curves of instantaneous, determined from chemical reactions (MIELI), A., ii, 153.

Thermal analysis. See Analysis.
Thermochemistry:

Thermal expansion, compressibility, atomic volume, and atomic heat of metals, relation between (Grüneisen), A., ii, 563.

and specific heat of metals (Grüneisen), A., ii, 563.

Atomic heat, atomic volume, thermal expansion, and compressibility of metals (Grüneisen), A., ii, 563.

Specific heat and molecular magnetic field of ferromagnetic substances (Weiss and Beck), A., ii, 659.

and osmotic pressure of solutions (v. Biron), A., ii, 459.

measurement of the variation of, with temperature (Lecher), A., ii, 83.

and thermal expansion of metals (Grüneisen), A., ii, 563.

of some elements and salts between the temperature of liquid air and room temperature (Nordmeyer), A., ii, 353.

of solid elements and Dulong and Petit's law (Wigand), A., ii, 13; (Rohland), A., ii, 459.

of liquids, new method for determining the (Richards and Rowe), A., ii, 806.

of isomorphous substances and their mixtures (Bogojawlensky and Winogradoff), A., ii, 806.

Heat of combustion of carbylamines and alkyl argenticyanides (Guillemand), A., i, 719.

of organic compounds, determination of the, by the platinum resistance thermometer (Fischer and Wrede), A., ii, 155.

Heat of formation of organic fluorocompounds (Swarts), A., ii, 354.

of quadrivalent oxygen compounds (McIntosh), A., ii, 355.

Heats of neutralisation, hydrolysis as illustrated by (Veley), A., ii, 813.

Heat of fusion, specific cohesion, and molecular weight at the melting point (Walden), A., ii, 1014.

Latent heats of fusion of isomorphous substances and their mixtures (Bogojawlensky and Winogradoff), A., ii, 806.

Critical temperatures. See under Critical.

Calorimetric study of slow reactions (Duclaux), A., ii, 154.

Temperature, and electrical conductivity, relation between (Rasch and Hinrichsen), A., ii, 149.

Thermochemistry:

Temperature and pressure in relation to orthobaric volumes (Haigh; Young), A., ii, 813.

Temperatures, constant, in drying ovens, appliance for (Habermann), A., ii, 17.

high, and high pressures, apparatus for experiments at (Threlfall), T., 1933; P., 191.

low, application of, to some chemical problems (Dewar and Jones), A., ii, 258.

very low, use of, for spectrum analysis, and for the study of magnetico-optical phenomena of solutions (Becquerel), A., ii, 3.

Temperature coefficient and ionic mobility, relation between (Rasch and Hinrichsen), A., ii, 149.

of ionic mobilities in water as a function of the mobilities (Rasch and Hinrichsen), A., ii, 148; (Kohlrausch), A., ii, 264.

Temperature velocities of various physiological actions (Snyder), A., ii, 768.

Ignition temperature and vapour pressure of inflammable liquids at low boiling point, relation between (Charitschko), A., ii, 255.

Transition points, determination of (Dunstan and Thole), T., 1819; P., 213.

Transition temperatures, influence of foreign substances on, and the determination of molecular weights (Dawson and Jackson), T., 844; P., 26.

Calorimeter, bomb, modified (Rengade), A., ii, 255.

Thermometer, gas, measurements with (Day and Clement), A., ii, 1013.

pentane, scale of the (Hoffmann and Rothe), A., ii, 152.

Thermo-regulator, a simple form of (Green), A., ii, 826.

Thermostat, water, for the normal temperature of 15° (Poda), A., ii, 83.

Thermostats, glass, for higher temperatures (Fischer and Bobertag), A., ii, 757.

Thermodynamics. See under Thermochemistry.

Thermometer, Thermo-regulator, and Thermostats. See under Thermochemistry.

Thetines, phenolic, and their reaction with benzoyl chloride (Barnett and Smiles), P., 123.
Thianthren. See Diphenylene disulphide.

Thiazines (Gnehm and Waldner), A., i, 63; (Gnehm and Schindler), A., i, 110; (Gnehm and Schönholzer), A., i, 112.

Thiethyl-dimethylcarbinol, -dipropylcarbinol, -heptylene, and -propylene (Thomas), A., i, 360.

Thio-aldehydes, formation of (Vanino), A., i, 318.

Thioamides, constitution of (Billmann), A., i, 142.

Thioantimonic acid. See under Antimony.

Thiocarbamide (Grossmann), A., i, 10. and ammonium thiocyanate, isomerism of (Patterson and McMillan), T., 1049; F., 193.

preparation of soluble and stable additive compounds of, with silver salts (Farbenfabriken vorm. F. Bayer & Co.), A., i, 613.

Thiocarbamides, reactions of, with acid chlorides (Dixon and Taylor), T., 18.

Thiocarbamidodiacetonitrile and its isomeride (V. Meyer and Lehmann), A., i, 910.

6-Thiocarbamido-2-p-toly1-4-methylpyrimidine (Johnson, Storey, and McCollum), A., i, 888.

Thiocarbigmides, action of, on the ethyl esters of malonic and cyanoacetic acids (Ruhemann), T., 621; P., 53.

Thiocyanates, containing an electronegative group, constitution of (Dixon and Taylor), T., 684; P., 73.

action of iodine on (Pfeiffer and Tilgner), A., i, 614.

Thiocyanic acid, constitution of (Palazzio and Scelsi), A., i, 718.

action of certain oxidising agents on (Bongiovanni), A., i, 770, 959.

detection of, by means of mercurous chloride (Pollacci), A., ii, 782.

Thiocyanoselenious acid. See under Selenium.

Thiocyano-. See also under the parent Substance.

Thiocyanuric acid. See under Cyanuric acid.

3-Thiomethyl-1:5-diphenylpyrazole and its 4-nitroso-derivativo and sulphone (Michaelis and Willert), A., i, 214.

5-Thioethyl-1:3-diphenylpyrazole and its 1-m-nitro-derivativo and their sulphones (Michaelis and Willert), A., i, 215.

Thionaphthen and its derivatives (Brezzik, Friedländer, and Koeniger), A., i, 200.

Thionaphthen derivatives, synthesis of, from styrenes and thionyl chloride (Barger and Ewings), T., 2086; P., 237.

Thionaphthen, hexachloro- and 1:2-dichloro-4:5(or 5:6)-dihydroxy-, and its benzoyl derivative (Barger and Ewings), T., 2086; P., 238.

3-hydroxy-, preparation of, and a red dye from it (Kalle & Co.), A., i, 673.

preparation of the leuco-derivativo of colouring matter obtained by oxidation from (Kalle & Co.), A., i, 785.

Thionaphthen-3-aldehyde, 2-hydroxy-(Friedländer), A., i, 373.

Thionaphthen-2-carboxylic acid, 3-hydroxy-, preparation of (Kalle & Co.), A., i, 797.

3-hydroxy-, preparation of, and a red dye from it (Kalle & Co.), A., i, 673.

dihydroxy-, preparation of (Farbwerke vorm. Meister, Lucius, & Bruning), A., i, 1004.

Thionaphthenindoleindigotins. See Indolylthionaphthenones.

Thionoxal-p-chloroanilide, -c-cumidide, -phenetidide, and -a- and -B-naphthylamides (Freichics and Wildy), A., i, 414.

Thionoxalotoluidides, o-, m-, and p-(Freichics and Wildy), A., i, 413.

Thionyl chloride. See under Sulphur.

Thionyltylglycollic acid and its salts, preparation of (Gazdar and Smiles), T., 1834; P., 216.

Thiophen, derivatives of (Thomas), A., i, 360.

Thiophen, bromo-derivatives (Capelle), A., i, 201.

3-Thiopyrine, 1-m-nitro- (Michaels and Stieglcr), A., i, 213.

Thiosulphonates, action of arsenites and cyanides on (Gutmann), A., i, 972.

volumetric estimation of (Gutmann), A., ii, 544.

Thiosulphuric acid. See under Sulphur.

Thiozone and its derivatives (Erdmann), A., ii, 831.

Thiozonides (Erdmann), A., ii, 830.

Thio-. See also under the parent Substance.

Thoria. See Thorium oxide.

Thorianite, new elements in (Evans), T., 666; P., 60; (Ojawa), A., ii, 952, 953.
Thorium and helium, association of, in minerals (Strutt), A., ii, 144.

presence of, in the soil at Rome (Blanc), A., ii, 248, 452.

quantitative spectra of (Leonard), A., ii, 645.

relative activity of emanation and active deposit from (Bronson), A., ii, 792.

emanation and actinium emanation, condensation of (Kinoshita), A., ii, 652.

specific radioactivity of, and the variation of the activity of, with chemical treatment and with time (McCoy and Ross), A., ii, 81.

distribution in electric fields of the active deposits of (Russo), A., ii, 552.

rate of production of helium from (Soddy), A., ii, 921.

Thorium alloy with nickel (Chauvenet), A., ii, 358.

Thorium compounds, nomenclature of (Hahn), A., ii, 464.

Thorium salts, abnormal behaviour of, on hydrolysis of (Denham), A., ii, 380.

Thorium fluoride (Duboin), A., ii, 298 ; (Chauvenet), A., ii, 597.

and oxyfluoride (Chauvenet), A., ii, 597.

hydroxide, heterogeneous colloidal (Szilárd), A., ii, 197.

hydroxides, colloidal (Szilárd), A., ii, 45.

mercuri-iodide (Duboin), A., ii, 598.

oxide (thorin), reduction of, by carbon (Greenwood), T., 1493 ; P., 188.

application to, of a general method of synthesis of fluorides and silicates (Duboin), A., ii, 297.

potassium silicate (Duboin), A., ii, 298.

sulphide and oxysulphide (Duboin), A., ii, 502.

Thorium, separation of, from titanium (Dittrich and Freund), A., ii, 134.

separation of titanium, zirconium, and, from iron (Dittrich and Freund), A., ii, 135.

See also Mesothorium and Radiothorium.

2-Threonic acid and its bruteine salt and phenylhydrazide (NeF), A., i, 7.

Thujene dihydrohaloids (Kondakoff), A., i, 195.

Thujone. See Tanacetone.

Thymamine, a protamine from the thymus gland (Nelson), A., i, 1030.

Thymine, formation of, by heating intestinal nucleic acid (Inouye), A., i, 931.

action of diazobenzensulphonic acid on (Johnson and Clapp), A., i, 931.

N-alkyl derivatives, synthesis of (Johnson and Clapp), A., i, 885.

benzyl derivatives, synthesis of (Johnson and Derby), A., i, 1018.

potassium derivative (Johnson and Clapp), A., i, 836.

separation of, from uracil (Johnson), A., i, 692.

Thyminglucophosphate, barium (Levène and Mandel), A., i, 587.

Thymol, synthesis of, and its methyl ether (Béhal and Tiffeneau), A., i, 630.

oxidation of, by the oxidising ferment of mushrooms (Cousin and Hérissey), A., i, 84.

Thymol, 2-bromo-, bromonitro-, and 2-nitro- (Robertson), T., 793 ; P., 73.

hydroxy-. See 4-Methylphenylidymethylcarbinol, 2-hydroxy-.

isoThymol, synthesis of, and its methyl ether (Béhal and Tiffeneau), A., i, 630.

Thymonucleic acid, constitution of (Levène and Mandel), A., i, 587.

Thymoquinol and its methyl ethers (Semmler), A., i, 279.

Thymoquinone, dihydroxy-, hydrolysis of (Fichter and Glaser), A., i, 660.

Thymoquinone-2-oxime-5-0-demethylcarbinol, 2-hydroxy-.

Thymus. See Glands.

Thymus glands. See Glands.

Thyroid glands. See Glands.

Tiglic aldehyde, action of magnesium organic compounds on (Abelmann), A., i, 2.

Time taken by substances in dissolving (Gaillard), A., ii, 567.

Tin, physico-chemical researches on (Cohen), A., ii, 558.

the electro-analytical deposition of (Sand), T., 1572 ; P., 189.

action of oxygen on copper, zinc, and, and on its alloys with copper (Jordis and Rosenhaupt), A., ii, 107.

Tin alloys with aluminium, hardness of (Saposnikoff), A., ii, 600.

with calcium (Donski), A., ii, 280.

with cobalt (Lewkonja), A., ii, 853 ; (Schemtschuschny and Belynsky), A., ii, 855.

with copper (Sackur and Pick), A., ii, 496 ; (Giolitti and Tavanti), A., ii, 946.
Tin alloys, with lead (Rosenhain and Tucker), A., ii, 1038.

hardness of (Saposhnikoff), A., ii, 294.
estimation of lead in (Holzmann), A., ii, 633.

with nickel (Voss), A., ii, 194.

with platinum (Podkopéeff), A., ii, 391.

Stannic chloride, partition of, between two metallic chlorides (v. Biron), A., ii, 297.
hydrolysis of (v. Biron), A. ii, 295.

of the type, \(M_2SnCl_4/M'SnCl_6\) (v. Biron), A., ii, 295, 296, 297.

Stannic oxide, reduction of (Dott), A., ii, 1075.

Stannic acids (Kühl), A., ii, 198.

Metastannic acid, absorptive power of, for nitric and hydrochloric acids (Jörgensen), A., ii, 261.

perStannates, electrolytic formation of (Coppadoro), A., ii, 596.

Tin, antimony, and arsenic, microchemical analysis of (Schoorl), A., ii, 777.
estimation of (Dott), A., ii, 989.
estimation of, volumetrically, by means of potassium dichromate (Reynolds), A., ii, 134.
estimation of, in alloys, slags, and ashes (Namias), A., ii, 326.

Tin-group, new element of the, in thorianite (Evans), T., 666; P., 60.

Tissues, fat and ester hydrolysis in (Saxl), A., ii, 873.

utilisation of sugars by the (McGuigan), A., ii, 406.

action of oxidising salts on the (Cusiny), A., ii, 1049.
distribution of phosphoproteins in (Plimmer and Scott), T., 1699; P., 200.

the superficial layer of cells and its relation to their permeability and to the staining of, by dyes (Robertson), A., ii, 120.

the nitro-molybdate method for the detection of phosphorus in (Nasmith and Fidlae), A., ii, 776.
estimation of fat and unsaponifiable matter in (Kumagawa and Suto), A., ii, 331; (Bérentrop), A., ii, 544.

Tissues, estimation of lactic acid in (Jerusalem), A., ii, 905.

animal, so-called antitoxic power of, towards strychnine (Pellacani and Follì), A., ii, 1062.

amount of arginine, histidine, and lysine in the hydrolytic products of (Wakeman), A., ii, 209.
inosite in (Rosenberger), A., ii, 573.

the peroxydases of (Batelli and Stern), A., ii, 964.

phytase in (McCollum and Hart), A., ii, 713.

embryonic, autolysis of, and catalase and lipase in (Mendel and Leavenworth), A., ii, 207.

transformation of glycogen by enzyme action in (Mendel and Saiki), A., ii, 207.

embryonic muscular and nervous (Mendel and Leavenworth), A., ii, 207.

Titanic sulphate. See under Titanium.

Titanium compound with aluminium (Manchot and Richter), A., ii, 40.

Titanofluoride, hydroxylamine derivative (Ebler and Schott), A., ii, 1031.

Titanium nitride (Ruff and Eisner), A., ii, 700.
nitrogen haloids, new (Ruff and Eisner), A., ii, 700.

phosphide (Gewecke), A., ii, 597.

Titanous iodide, TlI, (Defacqz and Copaux), A., ii, 699.

Titanic sulphate, electrolytic reduction of solutions of (Diethelm and Forster), A., ii, 320.

Titanill-dihydroxymaleic acid (Fenton), T., 1064; P., 133.

Titanium and zirconium, simultaneous precipitation of, in presence of iron (Dittrich and Freund), A., ii, 134.
detection of (Fenton), T., 1064; P., 133.
estimation of, volumetrically (Newton), A., ii, 325; (Gallo), A., ii, 780.

separation of, from thorium (Dittrich and Freund), A., ii, 134.

separation of thorium, zirconium, and, from iron (Dittrich and Freund) A., ii, 135.

separation of, from zirconium (Dittrich and Freund), A., ii, 134.

Titanous iodide. See under Titanium.

Tobacco, estimation of non-volatile organic acids in (Tóth), A., ii, 238.

Tobacco smoke (Habermann and Ehrenfeld), A., ii, 888.

Tolidine, formation of, from hydrotoluene (Van Loon), A., i, 831.

m-Tolil (Eckcrantz and Ahlqvist), A., i, 993.

p-Tolidoximes, isomeric, and their behaviour as to formation of complexes (Tschugaeff and Spiro), A., i, 686.

o-Tolualdehyde, 5-hydroxy-, ethylene ether (Gattermann), A., i, 34.

m-Tolualdehyde, 4-hydroxy-, and its azine, synthesis of (Gattermann), A., i, 8.

6-hydroxy-, ethylene ether, and its derivatives, synthesis of (Gattermann), A., i, 34.

p-Tolualdioxide peroxide (Tschugaeff and Spiro), A., i, 687.

Toluene, benzene, and acetone, dispersion in the electric spectra of (Colley), A., ii, 908.

chemical dynamics of the bromination of (Bruner and Dluska), A., i, 146.

simultaneous production of 1:6- and 2:7-dimethylanilines in the action of methylene dichloride, chloroform, or acetylene tetra-bromide on, in presence of aminium chloride (Lavaux), A., i, 151, 256.

aluminium bromide, electrolysis of (Neminsky and Plotnikoff), A., i, 407.

Toluene, di-o-bromo-o-nitro- (Ponzio), A., i, 869.

o-bromodinitro-, o-chlorodinitro-, and o-dinitro- and its phenylhydrazine salt (Ponzio and Charrrier), A., i, 522.

o-, m-, and p-chloro and -nitro-, oxidation of (Law and Perkin), T., 1634 ; P., 195.

2:4-dihydroxy-. See Crescorcinol.

2:5-dihydroxy-. See Ornolin.

2-iodo-4-nitro-, derivatives of, with polyvalent iodine (Willgerodt and Kök), A., i, 620.

p-nitro-, action of caustic alkalis on derivatives of (Green and Badiley), T., 1721 ; P., 201.

kinetics of the sulphonation of (Martinsen), A., ii, 572.

o-nitro-, transformation of, into the o-dinitro-compound (Ponzio), A., i, 869.
(Tolyl compounds, Me=1.)

(459)

Toluene-p-sulphonic acid, 2-amino-p-tolylester and sodium sulphobenzene-
5-azo-2-amino-p-tolyl ester (ANILIN-
FARBE. & EXTRAKT-FABRIK.
VORM. J. R. GEIGY), A., i, 1022.

2:4-diaminophenyl ester and its
diacetyl derivative, 2:4-dinitro-
phenyl ester, 2:4-dinitrophenyl-
pyridinium ester, and 3:5-dinitro-
tolyl ester (ULLMANN and NÁDAI),
A., i, 526.

3:5-dinitro-p-tolyl ester (ULLMANN),
A., i, 626.

Toluene-p-thiosulphonic acid, sodium
salt, action of arsenites and cyanides
on (GUTMANN), A., i, 972.

Toluic acid, chlorodinitro- (two) (KUNC-
KELL), A., i, 729.

o-, m-, and p-hydroxy-, hydrazine
compounds of (FRANZEN and EICH-
LER), A., i, 831.

o-Toluic acid, 4-hydroxy-, action of
bromine on (ZINCKE and BUFF),
A., i, 643.

m-Toluic acid, 5-bromo-6-hydroxy-
(Robertson), T., 789; P., 73.

p-Toluic acid, chloroimino-, chloro-
imino-2-nitro-, and imino-2-nitro-
isomeric esters of (HILPERT), A., i,
830.

2-hydroxy-, preparation and reduction
of (MELDUM and PERKIN), T.,
1420; P., 187.

p-Toluidines, anilides, and a-naphthal-
ides of normal fatty acids, melting
points of (Robertson), T., 1033;
P., 120.

o-Toluidine, action of dichloroacetic
acid on (V. OSTMESSENSKY), A., i,
82.

o-Toluidine, 4-nitro-, hydrochloride of
(WILLGERODT and KOK), A., i,
620.

p-Toluidine, preparation of, from mixed
toluidines by means of p-toluidine
hydrate (FRISWELL), A., i, 332.

action of glyoxylic acid on (V. OSTM-
MIESSENSKY), A., i, 889.

action of ethyl pyruvate on (SIMON),
A., i, 687, 738.

cobaltinitrite (HOFMANN and BUCH-
NER), A., i, 875.

picrates (SUIDA), A., i, 523.

p-Toluidine, 2-iodo-, and its salts
(WILLGERODT and GARTNER), A., i,
876.

Toluidines, o-, m-, and p-, action of
dichloroacetic acid on (HELLER), A.,
i, 217.

picrates of (VIGNON and ÉVIEUX), A.,
ii, 665.

Toluidines, o- and p-, acetyl derivatives.
See Aceto-o- and -p-toluidides.

(Tolyl compounds, Me=1.)

Toluidines, o- and p-, calcium deriv-
aves of (ERDMANN and VAN DER
SMISSEN), A., ii, 588.

1-o-Toluidino-4-hydroxyanthraquinone
and its acetate (GRANDMOUGIN), A.,
i, 808.

p-Toluidino-1-phenyltriazole, 3:5-(or
5:3)-amino-, and its acetyl derivative
(FROMM and WELLER), A., i, 702.

2-Toluidinopyrimidines, o- and p-, 6-
chloro-, and 6-amino- of the o-com-
ound (JOHNSON, STOREY, and
MCCOLLUM), A., i, 883.

Toluihns, o-, m-, and p- (EKECRANTZ and
AHLOVIST), A., i, 993.

Toluoyl-o-benzoic acid, o- and p-chloro-
(HELLER and SCHULKE), A., i, 994.

a-p-Toluoyl-ß-phenylhydrazine, ø-nitro-
ß-nitroso- and ß-nitroso- (PONZIO and
CHARRIER), A., i, 552.

Toluquinone-2-oxime-5-ø-mono-
and -5-op-di-nitrophenylhydrazones
(BORSCH), A., i, 67.

Tolusafarinines, alkylation, preparation
of (FARBWERKE VORN. MEISTER,
LUCIUS, & BRÜNING), A., i, 225.

o-Tolyl ß-bromoethyl ether (GATTER-
MANN), A., i, 32.

trimethylene ether, and its di-4-4'-
alddehyde (GATTERMANN), A., i,
34.

m-Tolyl ethylene ether (GATTERMANN),
A., i, 34.

p-Tolyl benzene, o-nitro-, and its reduc-
tion (AUWERS), A., i, 477.

Tolyl arsenites, o-, m-, and p- (LANG,
MACKEY, and GORTNER), T., 1870.
glycerol ethers, o-, m-, and p-
(SCHIVKOVITCH), A., i, 978.

p-Tolylacetalddehyde and its derivatives
(KLING), A., i, 188.

p-Tolylacetoxazine, ø-aroxino-
(PONZIO and GIOVETTI), A., i,
835.

Tolylamine.- See Toluoidino.

p-Tolylanthroxan (KIIEGL), A., i, 550.

Tolyl-5-arsinic acid (tolyl-5-arsenic acid),
2-amino-, and its sodium salt and its
N-acetyl derivative (PYMAN and
REYNOLDS), T., 1181; P., 143; (D.
and R. ADLER), A., i, 592.

2-hydroxy-, sodium salt (BARROW-
CLIFF, PYMAN, and REMFRY), T.,
1896.

Tolylarsonic acid (tolylarsonic acids),
amino-, and their acetyl derivatives
(GENDA and KAHN), A., i, 592.

Tolylazoacetoacetic acids, o- and p-,
ethyl esters, and their benzoylhydr-
azines (BULOW and SCHAUB), A., i,
705.

Tolylazo.- See also Tolueneazo.
INDEX OF SUBJECTS.

(Toly compounds, Me=1.)

β-p-Tolybenzylhydrazine and its hydrochloride and benzoil derivative (Schlenk), A., i, 738.

p-Tolybenzylidenecarbamidine (Schlenk), A., i, 738.

p-Tolybenzylmethylallylammonium iodide and hydrogen tartrate, resolution of (Everatt and Jones), T., 1790; P., 212.

p-Toly-ψ-benzylthiocarbamide, cyano- (Fromm and Weller), A., i, 703.

α-m-Toly-Δ4-butyrole and its dibromide (Grisskewitsch-Trochimowsky), A., i, 799.

Tolylicarboxic acids, o- and p-, calcium salts (Erdmann and Van der Smissen), A., ii, 588.

p-Tolylicarboxamide, 2-iodo-, and its N- nitroso-derivative (Willgerodt and Gartner), A., i, 876.

o-Toly chloromethyl ketone, 5-chloro- (3-chloro-6-chloroacetylthiourea) (Kunkell), A., i, 729.

N-Tolylidacetanilides, o-, m-, and p- (V. Meyer and Schumacher), A., i, 909.

p-Tolylidimethylcyanomethylenammonium iodide (V. Braun), A., i, 628.

5-p-Toly-5:5-dimethylhydantoin (Bailey and Randolph), A., i, 742.

Tolyethyl alcohols, o-, m-, and p- (Kling), A., i, 980.

m-Toly ethyl ketone and its oxime and semicarbazone (Wallach and Rentschler), A., i, 405.

β-m-Toly-1-ethylpropionic acid, β-hydroxy-, synthesis and properties of, and its ethyl ester and salts (Grisskewitsch-Trochimowsky), A., i, 799.

β-β-Tolyglutaric acid, nitration of, and its 3-nitro-5-amino-derivative (Avery and Upson), A., i, 796.

p-Tolylguanido-p-toly-ψ-benzylthiocarbamide (Fromm and Weller), A., i, 701.

p-Tolylguanido-p-tolylthiocarbamide and its acetyl derivative and its anhydro-compound (Fromm and Weller), A., i, 701.

3-p-Tolyhydantoic acid and its ethyl ester (Bailey and Randolph), A., i, 741.

p-Tolylideneacetone (Meerwein), A., i, 90.

p-Tolylidenebismuridoxime (Conduché), A., i, 155.

o-Tolylidenmalonic acid, methyl ester (Meerwein), A., i, 90.

p-Tolylmethylenacetanilide, m-bromo-, and its platinchloride and picrate (V. Braun), A., i, 626.

(Toly compounds, Me=1.)

1-o-Toly-2-methylbenzimiazole, 4:7-dinitro-6-hydroxy-, and its silver salt, acetyl derivative, and ethyl ether (Meldola and Hay), T., 1672.

1-p-Toly-2-methylbenzimiazole, 4:7-dinitro-6-hydroxy-, and its salts and ethyl ether (Meldola and Hay), T., 1673.

n-O-toly methylecyanamide (V. Braun), A., i, 655.

p-O-toly methylecyanamide (V. Braun), A., i, 626.

o-Toly-o'-methylimesatin (V. Ostromissensky), A., i, 82.

p-Toly-p'-methylimesatin (V. Ostromissensky), A., i, 889.

1-p-Toly-3-methylpyrazole-5-sulphonic acid and its derivatives (Michaelis and Dulk), A., i, 692.

1-p-Toly-3-methylpyrazolone, 5-thio-, and its derivatives (Michaelis and Dulk), A., i, 691.

2-p-Toly-4-methylpyrimidine, 6-amino-, 6-chloro-, 6-thio-, 6-thiocyanate-, and 6-thiocarbimido-derivative (Johnson, Storey, and McCollum), A., i, 838.

b-p-Toly-α-α-naphthylcarbamide, α-hydroxy- (Scheiber and Beckmann), A., i, 725.

o-Tolynitrosoamine, N-benzoyl derivative (Jacobsen and Huber), A., i, 299.

4-Tolyoxy-4:7-dimethylhydrocoumarin (Fries and Klostermann), A., i, 822.

β-p-Topylpropionic acid, β-hydroxy-, synthesis of, and its ethyl ester and salts (Andrieskwy), A., i, 799.

3-m-Tolylrhodanic acid and its condensation with aldehydes (Andrieskwy), A., i, 683.

m-Tolylthioguanacetic acid, ethyl ester (Andrieskwy), A., i, 683.

p-Tolylthioacetic acid, preparation of (Kalle & Co.), A., i, 605.

p-Tolylthiopyrine (Michaelis and Dulk), A., i, 691.

p-Tolylthiuret, action of aromatic amines and hydrazines on (Fromm and Weller), A., i, 701.

2-Toly-α-tolylidiononato salts, 4-nitro- (Willgerodt and Kok), A., i, 620.

Tomatoes, ripening of (Albahary), A., ii, 774.

Tourmaline from Asinara, Sardinia (Serra), A., ii, 116.

new mineral occurring with, in Madagascar (Lacroix), A., ii, 705.

Toxicological investigations, tannic acid in (Biginelli), A., i, 40.
Toxicology, isolation of traces of mineral substances from saline mixtures in (Meillère), A., ii, 62.

Toxins, action in the dark of fluorescent substances on, and its reversibility (Kudo and Jodlbauer), A., ii, 867. See also Tetanus toxin.

Toxoleithides (Minz), A., ii, 413.

Trametes suaveolens, chemistry of (Zeller), A., ii, 216.

Transference numbers. See under Electrochemistry.

Transformation, law of, in stages and radioactivity (Schmidt), A., ii, 550. reciprocal, of isomerides under the influence of chemical induction (Tanatar), A., i, 750.

Transition concentrations. See under Affinity, chemical.

Trees, proteaceous, aluminium in (Smith), A., ii, 855.

Triacetylmethylbaptigenetin (Gorter), A., i, 98.

Triacetyl-. See also under the parent Substance.

Trianiinosilicon (Ruff), A., i, 966.

Trianiisylseleninum and its chloride, dichromate, hydroxide, iodide, and platinichloride (Hilditch and Smiles), T., 1387.

Trianiisylsulphonium and its platinichloride (Smiles and Le Rossignol), T., 755.

Triazane, preparation of (Michaelis), A., i, 471; (Goldschmidt), A., i, 572.

Triazines, naphthalenoid,azo-derivatives of (Cassella & Co.), A., i, 482.

Triazocetaldehyde (Forster and Fierz), T., 1865; P., 227.

Triazocetic acid and its salts, ethyl ester, and amide (Forster and Fierz), T., 72. dissociation constants of (Philip), T., 925; P., 114.

Triazocetone (acetonylazoinid) and its oxime and semicarbazone, and the p-toluene-sulphonpheric derivative of the oxime (Forster and Fierz), T., 72.

1-Triazobutanone-2 and its semicarbazone, and its oxime and its p-toluene-sulphonyl derivative, and 3-Triazo-

Triazo-compounds, refraction and dispersion of (Philip), T., 918; P., 114.

Triazothyl alcohol (2-triazoethanol-1) and its acetate and p-nitrobenzoate (Forster and Fierz), T., 1865; P., 227.

Triazoformic acid, ethyl ester (Forster and Fierz), T., 51.

Triazogroup, the (Forster and Fierz), T., 72, 669, 1070, 1174, 1859, 1865; P., 54, 102, 143, 226, 227.

Triazole derivatives from dinitriles (v. Meyer and Schumacher), A., i, 912.

Triazo-ketones, a¾-dibromo- (Forster and Fierz), T., 1178.

α-Triazobropionic acid and its ethyl ester, silver salt, and amide (Forster and Fierz), T., 671; P., 54.

Tiunonol, resolution of, and its reduction to alanine, and the levor- and its brucine salt, ethyl ester, and amide (Forster and Fierz), T., 1859; P., 226.

dissociation constants of (Philip), T., 925; P., 114.

β-Triazobropionic acid, ethyl ester (Forster and Fierz), T., 674; P., 54.

Tribenzyol-. See under the parent Substance.

Tribenzyl-silicol and silicyle chloride (Robison and Kipping), T., 450; P., 25.

Tribenylsulphine salts (Hofmann and Ott), A., i, 84.

Triboluminescence of mineral substances (Karl), A., ii, 549.

of racemic compounds (Gernez), A., ii, 748.

Tricalcium phosphate. See under Calcium.

Tricarballylic acid, glcinum salt (Tanatar and Kurovskii), A., i, 758.

Tricarbon series (Wohl, Schwitzter, Köppen, Roth, and Lange), A., i, 941.

Triethylcarbinol, chloro-. See Diethyl-

β-chloroethylecarbinol.

Triketone, C₁₆H₁₉O₃, from the sodium derivative of acetylaceton and β-chloroethyl ethyl ketone (Blaise and MAIRE), A., i, 391.

Trimellitic acid, preparation of (Schultze), A., i, 356.

3:4:5-Trimethoxy-1-allylbenzene. See Elemicin.

Trimethoxyxanthraquinone, hydroxy-

(Bentley and Weizmann), T., 437; P., 52.

3:4:5-Trimethoxybenzaldehyde. See Trimethylgalgalaldehyde.

3:4:5-Trimethoxybenzolic acid and nitro-

and their ethyl esters (Pollak and Feldschreiber), A., i, 543.
3:4:5-Trimethoxybenzonitrile (Semm-LER), A., i, 558.

3:4:5-Trimethoxybenzoyl cyanide (MAUTHNER), A., i, 348.

Trimethoxy-2-benzoylbenzoic acid, 2'-3'-4'-(or 3'-4':5') (BENTLEY and WIEZMANN), T., 436; P., 52.

4:5:4'-Trimethoxy-2-benzoylbenzoic acid, 2'-hydroxy-, preparation of (PERKIN and ROBINSON), T., 513.

Trimethoxybenzylidenebisacetophenone (MAUTHNER), A., i, 729.

Trimethoxybenzylquinoxaline (MAUTHNER), A., i, 986.

2:5:10-Trimethoxybrazan (V. KOSTANECKI and LAMPE), A., i, 907.

2:7:8-Trimethoxybrazanquinone, trim- nitro- (V. KOSTANECKI and LAMPE), A., i, 907.

7:4':5'-Trimethoxy-2:3-indenobenzopyranol (PERKIN and ROBINSON), T., 1106.

7:4':5'-Trimethoxy-4:3-indenobenzopyranol (PERKIN and ROBINSON), T., 1151.

2:4':3'-Trimethoxy-6-methylbenzoylacetophenone (TAMBOR), A., i, 350.

3:4:5-Trimethoxy-a-methylcinnamic acid (MAUTHNER), A., i, 729.

a:4:5'-Trimethoxy-8'-phenoxy-8-phenyl-iso-butyric acid, 2:5:2'-trihydroxy-, lactone of, and its acetyl derivative (ENGELS, PERKIN, and ROBINSON), T., 1156.

3:4:5-Trimethoxyphenylacetic acid (methyltrifluoro acid, trimethylhomogallic acid), synthesis of (MAUTHNER), A., i, 896.

and its methyl ester (SEMMLER), A., i, 558.

 trimethoxyphenylglyoxylic acid and its phenylhydrzone and amide (MAUTHNER), A., i, 548.

trimethoxyphenvlaldehyde with its phenylhydrzone and amide (MAUTHNER), A., i, 729.

3:4:5-Trimethoxyphenolpyruvic acid and its oxime (MAUTHNER), A., i, 986.

trimethoxyphthalic acid from cumbamine methyl ether (FEIST), A., i, 102.

3:4:5-Trimethoxyphthalic acid. See Gallocarboxylic acid trimethyl ether.

3:4:5-Trimethoxy-1-propenylbenzene. See isoKleminic.

Trimethoxytriphenylcarbinol and its acetyl derivative (HERZIG), A., i, 880.

2:4:5-Trimehyaladipic acid, 2'-hydroxy- (AUWERS and HESSENDEN), A., i, 551.

3:1:5-Trimethylbenzene. See Mesitylene.

Trimethylandicetoacetatic acid, a-cyano-, ethyl ester, betaine (BENARY), A., i, 601.

Trimethyladambromphenylmethane and its nitroso-derivative (V. BRAUN), A., i, 685.

Trimethylbrazilein and its derivatives (ENGELS, PERKIN, and ROBINSON), T., 1133.

Trimethylbrazilone (ENGELS, PERKIN, and ROBINSON), T., 1144.

constitution of (PERKIN and ROBINSON), T., 498.

Trimethylbrazilein, oxidation of, to 2-carboxy-4:5-dimethoxyphenylacetic acid (PERKIN and ROBINSON), T., 516.

1:3:7-TrimethylcarbazoIe and its picrate (BORSCHE, WITTE, and BOTHE), A., i, 367.

Trimethylcarbinol and phenol, densities of solutions of (PATERNÓ and MIELI), A., i, 383.

trimethylurethane of (VALLÉE), A., i, 976.

Trimethylcarbinol, amino-, and its platinichloride (KRASSUSKY), A., i, 139.

3:4:5-Trimethylcarbonobenzonic acid and its bromo-derivative and pyridine salt, and its chloride and anilide (FISCHER), A., i, 893.

p-Trimethylcarbonobenzoylbenzoic acid (FISCHER), A., i, 895.

3:4:7-Trimethylcoumarin and its additive salts, oxime, and phenylhydrzone (CLAYTON), T., 529; P., 26.

Trimethylidihydrobrazileinol, formation of (ENGELS, PERKIN, and ROBINSON), T., 1136.

2:4:6-Trimethyldihydropyrindine, 3:5-di- (M. MEYER and KLEINSTÜCK), A., i, 910.

cycloTrimethylene. See cycloPropane.
Triphenylmethane, absorption spectrum of (Leonard), P., i, 93.

oxidation of (Law and Perkin), T., 1637; P., 195.
	nature of the impurity found in preparations of (Hartley), P., 94.

some o-benzylated dyes from (Guyot and Pignet), A., i, 569.

Triphenylmethane, α-bromo-, compound of, with hydrogen bromide (Meyer), A., i, 731.

α-chloro-, compound of, with hydrogen chloride (Meyer), A., i, 731.

trihalogen derivatives, crystallography of (Jaeger), A., i, 523.

α-nitro-, synthesis of (Kliegl), A., i, 82.

production of, from dinitrodiphenyl-aminesulphonlic acids (Badische Anilin- & Soda-Fabrik), A., i, 154.

colour bases of (Noelting and Philippe), A., i, 295.

influence of methyl groups on the tinctorial properties of (Bielecki and Koleniew), A., i, 697.

Triphenylmethane series, cause of colour in the (Green), P., 206.

amino-oxides of leuco-bases of the (Bamberger and Rudolf), A., i, 1011.

Triphenylmethyl, preparation and structural formula of (Schmidlin), A., i, 150.

coloured and colourless (Schmidlin), A., i, 629; (Flurksheim), A., i, 871.

fumarate and triphenylacetate (Anschütz), A., i, 331.

Triphenylmethylymalonic acid, methyl ester (Fosse), A., i, 86.

Triphenylmethysilicane (Marsden and Kipping), T., 210; P., 12.

Triphenyl-α-naphthylquinomethane (Tschitschibabin), A., i, 872.

Triphenylphosphoryl dichloride (Autenrieth and Geyer), A., i, 157.

αβ-Phenylpropionic acid, synthesis of, and its ethyl ester (Eykmann), A., i, 796.

Triphenyl-silicic and -silicyl chloride (Marsden and Kipping), T., 208.

Triphenylstibine sulphide (Kaufmann), A., i, 1081.

Triphenyl-p-tolyquinomethane (Tschitschibabin), A., i, 873.

Triphenyltraazine (Rolla), A., i, 474.

Triplodibenzyldieneacetone tetrasulphide (Fromm and McKee), A., i, 991.

Trispropaldehydehexaethylacetalamine and its derivatives (Wohland and Grosse), A., i, 49.

Tripropylersine (Dehn and Williams), A., i, 721.

Trisbenzenesulphonate (Vignon), A., i, 1025.

formation of (Heller), A., i, 300.

benzenesulphonyl ester (Grandmougin and Freimann), A., i, 1023.

Tris-α-dimethoxyphenylsulphonium and its chloride and platinichloride (Smiles and Le Rossignol), T., 757.

Trisilico-xyloylsilicic acid (Kotinshsky and Serogenkoff), A., 1032.

Tris-α-methoxytolysulphonium platinichloride (Smiles and Le Rossignol), T., 756.

Tris-α-methoxytolysulphonium and its platinichloride (Smiles and Le Rossignol), T., 759.

Tris-5-methoxyα-xylyl-2-sulphonium chloride and platinichloride (Smiles and Le Rossignol), T., 762.

Triphenylmalononitrile (Hessler), A., i, 182.

Tris-α- and -p-toluenesazophenols and their acyl derivatives (Grandmougin and Freimann), A., i, 1023.

Tritan series (v. Liebig, Herb, and Keim), A., i, 445; (v. Liebig), A., i, 540.

Tritancarboxylic acids (v. Liebig), A., i, 445, 540.

Tritanic acid, p-hydroxy- (v. Liebig), A., i, 541.

Tritanolate, isomeric dihydroxy-, and 2:3:4-trihydroxy- (v. Liebig), A., i, 541.

Tritanolactonesulphonium acid, 2:4-di hydroxy-, and its derivatives (v. Liebig and Herb), A., i, 449.

Tritanol-5-sulphonium acid, 2:4-dihydroxy- (v. Liebig and Herb), A., i, 450.

Trithioformaldehyde, formation of (Vannino), A., i, 318.
Trithionates. See under Sulphur.

p-Triflylactic acid (Schmidlin and Hodgson), A., i, 171.

Tritylphosphoryl dichlorides, o-, m-, and p- (Autenrieth and Geyer), A., i, 357.

Tri-o-tolylsulphonylhydroxylamine (Haga), A., i, 571.

Trixanthyl derivatives, new (Silber-Rad and Roy), P., 205.

Tropacocaine, reactions of (Reichard), A., ii, 643.

Tropelines, halogen-substituted (Wolffenstein and Rolle), A., i, 282.

Tropic acid, chloride of (Wolffenstein and Mamlock), A., i, 281.

Tropine and its derivatives, affinity values of (Veley), P., 280.

Tropine and its additive salts (Schmidt and Kircher), A., i, 675.

Tropinone methiodide and its benzoyl derivative (Rabe, Schneider, and Brasch), A., i, 361.

Trypanosome studies, chemo-therapeutic (Ehrlich and Franke), A., ii, 411.

Trypanosomes and arsenic acids (Pyman and Reynolds), T., 1160; P., 143; (Barrowcliff, Pyman, and Remy), T., 1893; P., 229.

mechanism of the action of arsenic preparations on, in the organism (Jacoby and Schütze), A., ii, 771, 973.

Trypsin, activity of, and a simple method for its estimation (Fuld), A., ii, 489.
causes of rise in electrical conductivity under the influence of (Bayliss), A., ii, 118.

alleged formation of bile acids and bile pigments by the action of, on hemoglobin (Hollis), A., ii, 408.
detection of (Jacoby), A., ii, 743.
simple method of estimating the activity of (Gross), A., i, 284.

Tryptase, adsorption of, by solids (Buchner and Klatt), A., i, 489.

Tryptphan and hydroxy- (Abderhalden and Baumann), A., i, 488.
synthetic, and some of its derivatives (Ellinger and Flamand), A., i, 378.

optical behaviour of (Fischer), A., i, 378.
derivatives (Abderhalden and Baumann), A., i, 932.
vannillin-hydrochloric acid as a test for (Rosenthaler), A., ii, 76.

Tryptophan-naphthylcarbimides (Ellinger and Flamand), A., i, 378.

Tsubaki-abura. See Camellia oil, Japanese.

Tubercle bacillus. See under Bacillus. XCIV. ii.

Tubes for saccharimeters (Rousset), A., ii, 73; (Pellet), A., ii, 235.
quartz, in thermal analysis (Schoen), A., ii, 1015.
See also Capillary tubes and Inlet-tube.

Tubing, rubber. See Rubber tubing.

Tumour of the breast, contents of a cystic (Zdarek), A., ii, 1059.

Tumours, crystals in (White), A., ii, 972.
See also Mouse tumours.

Tungsten, quantitative spectra of (Leonard), A., ii, 645.
and molybdenum, halogen compounds of (Rosenheim and Garfunkel), A., i, 614.

Tungsten oxide, reduction of, by carbon (Greenwood), T., 1493; P., 188.

Tungstic acid, estimation of, and its separation from other substances (Bourion), A., ii, 737.
separation of, from phosphoric acid (v. Knorbe), A., ii, 231.
separation of, from silica (Defacoz), A., ii, 737; (Nicolardot), A., ii, 1074.

Tungsten silicide, WSi2 (Defacoz), A., ii, 595.

Tungsten, complex ozo-salts of (Mazzucelli and Inghilleri), A., i, 755.

and chromium, estimation of, in steel (Hinrichsen and Wolter), A., ii, 900.

separation of, from chromium (v. Knorre), A., ii, 779.

Tungstic acid. See under Tungsten.

Tungette and meymaite (Walker), A., ii, 507.

Turbine funnel. See Funnel.

Turmeric oil (Rupe), A., i, 95.

Tartaric acid (Adan)."
INDEX OF SUBJECTS.

Turpentine oil, Russian (Schindelmeis-er), A., ii, 95.

Turpentine oils, optical rotation of (Héry), A., i, 434.

Tyrosinase and \( \tau \)-tyrosine (Bertrand and Rosenblatt), A., i, 379.

mode of action of (Bach), A., i, 237.

from _Russusula delica_, action of, on poly-

peptides which contain tyrosine and on suprarenine (Abder-

halden and Guggenheim), A., i, 1030.

action of, on tyrosine, tyrosine-con-

taining polypeptides, and other com-

pounds (Abderhalden and Guggenheim), A., i, 237.

action of, on some substances related to tyrosine (Bertrand), A., i, 236.

peroxydas active in (Bach), A., i, 237.

Tyrosine and its hydrobromide and hydriodide (Aloy and Rabaut), A.,

i, 541.

and its derivatives, action of tyrosinase on (Bertrand), A., i, 236; (Abder-

halden and Guggenheim), A., i, 237, 1030.

derivatives, synthesis of (Fischer), A.,

i, 544, 887.

\( \tau \)-Tyrosine derivatives, synthesis of (Abderhalden and Hirszowski),

A., i, 887.

\( \tau \)-Tyrosine, 2:5-diodo-, derivatives of (Abderhalden and Guggenheim),

A., i, 420, 886; (Abderhalden and Hirszowski), A., i, 888.

Tysonite, absorption spectra of, and the changes undergo in a magnetic field, at the temperatures of liquefaction and solidification of hydrogen (Be-

quibel and Onnes), A., ii, 338.

U.

Ultra-filters, permeability of (Bechhold),

A., ii, 24, 823.

Ultramarine, constitution of (Erdmann),

A., ii, 532.

Ultra-microscopic observations (Reissig,

A., ii, 933.

Umbellulone, constitution of (Tutin),

T., 252; P., 23; (Semmler), A., i, 92.

Undecaldehyde and its oxime, prepara-

tion of (Bouveault), A., i, 118.

Undecenoic acid, derivatives of (Born-

water), A., i, 74.

See also a3C-Tri methyl-\( \Delta \)-octenoic acid.

\( \gamma \)-Undecolactone (Shukoff and Sches-

takoff), A., i, 755.

Unit-stere theory, the (Le Bas), A., ii, 667.

Unsaturated acids. See under Acids.

Unsaturated compounds (Ponser and

Baumgarth), A., i, 21.

action of semicarbazide on (Rupe and

Hinterlach), A., i, 12.

the “hydrogen number” as a means for determining, in a manner similar to the iodine numbers of Hübl and Wys (Fokin), A., ii, 637.

Unsaturation and optical activity, relation

between (Hilditch), T., 1, 700, 1388, 1618; P., 61, 186, 195.

Uracil, action of diazobenzensulphonic acid on (Johnson and Clapp), A.,

i, 981.

\( \tau \)-alkyl derivatives, synthesis of (John-

son and Clapp), A., i, 535.

benzyl derivatives, synthesis of (John-

son and Derby), A., i, 1018.

potassium derivative (Johnson and Clapp), A., i, 836.

separation of, from thymine, and its 5-

nitro-derivative (Johnson), A., i, 692, 739.

Uracil, 5-chloro- (Johnson), A., i, 739.

Uracil-3-acetic acid, synthesis of, and its methyl ester, salts, and 5-bromo-

and 5-nitro-derivatives (Wheeler and Lidde), A., i, 692.

Uracil-4-acetic acid, synthesis of, and its esters, potassium salt and 5-nitro-

(Wheeler and Lidde), A., i, 693.

Ural, bromo- (bromoisovalerylcarbamid),

as a narcotic (Van der Eeckhout), A.,

ii, 55.

Uranium, preparation of (Giolitti and

Tavanti), A., ii, 951.

specific radioactivity of (McCoy and

Ross), A., ii, 80.

scattering of \( \beta \)-rays from, by matter (Crowther), A., ii, 247.

and radium, relation between (Soddy),

A., ii, 919.

rate of production of helium from (Soddy), A., ii, 921.

Uranium compounds, anomalous be-

haviour in the radioactivity of certain (Schuldt and Moore), A., ii, 144.

Uranium tetraiodide (Guichard), A., ii, 45.

hepta- and octa-molybdates (Lancien),

A., ii, 699.

dioxide, reduction of, by carbon (Greenwood), T., 1492; P., 188.

sulphate of tervalent (Rosenheim and

Loebel), A., ii, 294.

Uranous oxide, molecular weight of (Oechsner de Coninck), A., ii, 501.

Uranyl hydroxide, colloidal (Szilard),

A., ii, 45, 197.
Uranium:

Uranyl molybdate, radioactivity of (V. Bartal), A., ii, 10.

sulphate and thallium sulphate, double salt of (Kohn), A., ii, 696.

Uranium X, radiation of (Levin), A., ii, 919.

Uranium minerals, radioactivity of (Boltwood), A., ii, 454.

Uranous and Uranyl salts. See under Uranium.

Urazoles (Acree, Johnson, Brunel, Shadinger, and Niedlinger), A., i, 919.

constitution and affinity constants of (Acree and Shadinger), A., i, 224.

velocity constants and mechanism of the reactions of alkyl halides with, and urazole salts (Acree and Shadinger), A., ii, 163.

Urea and ammonia, Spiro's and Folin's methods of estimating (Howe and Hawk), A., ii, 426.

ammonia distillation in presence of magnesium or calcium salts in the estimation of (Kober), A., ii, 893.

See also Carbamide.

Urethane, bromination of (Diels and Ochs), A., i, 10.

Urethane, hydroxy-, constitution of (Conduché), A., i, 155.

Uric acid, origin of, and its relation to digestion (Brugsch and Schittenhelm), A., ii, 611.

endogenous, origin of (Cathcart, Kennaway, and Leathes), A., ii, 715.

of the urine (Determeyer and Wagner), A., ii, 122.

formation of, in the liver of birds (Friedmann and Mandel), A., ii, 1054.

relation of glycine to (Samuely), A., i, 226.

changes in, in animals and men (Croftan), A., ii, 307.

metabolism. See under Metabolism. compound of, with nucleic acid (Seo), A., i, 70.

derivatives, affinity constants of, as determined by the aid of methyl-orange (Veley), T., 664; F., 50.

Uric acid, salts, physico-chemical researches on the behaviour of, in solution (Gudzent), A., i, 704.

Uricolysis, glycine as a product of (Stookey), A., i, 373.

Urinary indoxyll. See Indoxyl.

pigments derived from Indole (Benedicti), A., ii, 1057.

Urine, degree of acidity of (Jolles), A., ii, 970.

Urine, constituents of, precipitable by phenylhydrazine (Milrath), A., ii, 716.

amino-acids in, during pregnancy (van Liersum), A., ii, 715.

the fundamental colouring matter of (Dabrowski), A., i, 232.

creatinine in, of infants’ (Funaro), A., ii, 716.

glycine of normal (Emden and Marx), A., ii, 518.

occurrence and detection of glyoxylic acid in human (Granström), A., ii, 122.

regular occurrence of indole in (Jaffé), A., ii, 1057.

levulose in diabetic (Borchardt), A., ii, 518.

distribution of nitrogen amongst the various products in human (Maillard), A., ii, 1056.

a thermosoluble protein, said to be that of Bence-Jones in (Grimbert), A., ii, 212; (Gascard and Devalmont), A., ii, 519.

occurrence of proteose in (Borchardt), A., ii, 957.

uric acid of the (Determeyer and Wagner), A., ii, 122.

efficiency of thymol and refrigeration for the preservation of (Hawk and Grindley), A., ii, 409.

elimination of alanine by (Brugsch and Hirsch), A., ii, 611.

the elimination of nondialysable substances by, under normal and pathological conditions (Ebbecke), A., ii, 874.

relationship between the hourly output of nitrogen in, and resorption from the intestine, and its dependence on rest, work, and diuresis (Haas), A., ii, 874.

excretion of pigments by (Höber and Kempner), A., ii, 716; (Höber and Chassin), A., ii, 875.

blood and red pigmented (Florence), A., ii, 442.

Urine, analytical processes relating to:

analysis, use of potassium ferrocyanide and zine acetate as defecating agents in (Carrez), A., ii, 329.

reactions of (de Jæger), A., ii, 630.

Arnold's reaction of, with sodium nitroprusside (Holobut), A., ii, 716.

a colour reaction of pathological (Gauff), A., ii, 875.

influence of meat on the dimethylaminobenzaldehyde reaction of (Herter), A., ii, 410.
Urine, analytical processes relating to:—

haemaphaetic reaction of (Dufau), A., ii, 410.
the relation of nitrifying bacteria to the urorosein reaction of Nencki and Sieber (Herter), A., ii, 212.
detection of arsenic in (Salkowski), A., ii, 734.
detection of benzoic acid and glycine in (Seo), A., ii, 518.
the reactions for bile pigments in (Schippers), A., ii, 443; (Macadie), A., ii, 743.
detection of dextrose in (Otto), A., ii, 739.
detection of glycuronic acid and its derivatives in (B. Tollens), A., ii, 639; (K. Tollens), A., ii, 740.
detection of glyoxylic acid in human (Granström), A., ii, 122.
test for hippuric acid in (Dein), A., ii, 907.
detection and estimation of β-hydroxybutyric acid in (Shaffer; Black), A., ii, 992.
detection of indican in (Salkowski), A., ii, 999.
detection of organic bases in (Engelhard), A., ii, 1056.
estimation of acetone in (Hart), A., ii, 783.
criticism of Joule's process for estimating the acidity of (Repiton), A., ii, 644.
estimation of albumin in, by Esbach's method (Van der Harst), A., ii, 643.
estimation of ammonia in (Hawe and Hawk), A., ii, 426; (Malfatti), A., ii, 531; (Steel and Gies), A., ii, 776; (Ronchese), A., ii, 983.
detection of arsenic in (Sanger and Black), A., ii, 65.
estimation of the fundamental colouring matter of (Browninski and Dabrowski), A., ii, 443.
estimation of cystine in (Gaskell), A., ii, 75.
use of nitrous acid, nitrites, and aqua regia in the estimation of the mineral constituents of (Kastle), A., ii, 982.
estimation of nitrogen in (Hawk), A., ii, 64.
estimation of pentoses in (Jolles), A., ii, 235.
estimation of phosphates in (Ferraro), A., ii, 733.
estimation of reducing substances in, of infants' (Funaro), A., ii, 715.

Urine, analytical processes relating to:—
estimation of small quantities of sugar in (Schöndorff), A., ii, 311.
value of the different methods for estimating sugars in (Funk), A., ii, 902.
estimation of total sulphur in (Schulz), A., ii, 129; (Östberg and Wolf), A., ii, 426; (Konschego), A., ii, 628.
Spiro and Folin's methods of estimating urea in (Hawe and Hawk), A., ii, 426.
Folin's method of separating acetone and acetoacetic acid in (Hart), A., ii, 742.
separation of hippuric acid from (Roaf), A., i, 534.
See Alcaptonuria, Cystinuria, Diabetes, Diuresis, Excretion, and Pentosuria.

Urobilin, excretion of, in disease (Surveyor), A., ii, 1057.
Urocanic acid, occurrence of, in a pancreatic digest (Hunter), A., ii, 710.
Urocarmine, non-existence of, as a new and definite colouring matter (Mailhard), A., i, 486.
Urochrome and bromo- (Hohlweg), A., i, 1027; (Salomonsen; Mancini), A., i, 1028.
preparation of (Bocchi), A., i, 69.
preparation and estimation of (Dabrowski), A., i, 232.
excretion of, in man (Dombrowski), A., ii, 212.
Uroleucic acid (Garrod and Hurtley), A., ii, 54.
Uropyrrol (Mancini), A., i, 1028.
Urorosein, indoleacetic acid as the chromogen of (Herter), A., ii, 410.
Urotropine. See Hexamethylenetetramine.

Urushiol (Miyama), A., i, 437.
Uterus, mammalian, action of drugs on the (Fardon), A., ii, 1055.

V.

Vacuum regulator, a new (Holtermann), A., ii, 99.
Valency and the electron theory (Stark), A., ii, 138; (Kauffman), A., ii, 478.
on an atomistic electrical basis (Stark), A., ii, 138, 574.
thorval and the constitution of salts (Wyrouboff), A., ii, 368.
new theory of (Friend), T., 260, 1006; F., 14, 122.
n-Valeric acid, a-amino-, oxidation of, with hydrogen peroxide (Dakin), A., i, 80.
γ-δ-disubstituted, preparation of (Sörensen), A., i, 931.
ε-amino-γ-δ-dihydroxy-, preparation of, and its copper salt (Fischer and Kramer), A., i, 858.
γ-iodo-δ-hydroxy-, lactone of (Bouguault), A., i, 538.
See also a-Methylbutyric acid.
isoValeric acid, a-amino-, oxidation of, with hydrogen peroxide (Dakin), A., i, 80.
a-bromo- (Fischer and Scheibler), A., i, 324.
a-hydroxy-, and its optical properties (Fischer and Scheibler), A., i, 857.
Valeric acid group, hypnotic action of the (van der Eekhout), A., ii, 55.
isoValeryl chloride, d-a-bromo-(Fischer and Scheibler), A., i, 858.
isoValerylcarbamide, bromo-. See Ural.
a-chloro-, preparation of (Knoll & Co.), A., i, 399.
a-iodo-, preparation of (Knoll & Co.), A., i, 769.
isoValerylethylamide (Einhorn), A., i, 610.
isoValerylglycine, d-a-bromo-, and d-a-hydroxy-, zinc salt, and its optical properties (Fischer and Scheibler), A., i, 858.
isoValerylideneacetone and its semicarbazido-semicarbazone (Rüpe and Hinterlach), A., i, 13.
isoValeryl-lactamide (Einhorn), A., i, 611.
isoValerylquinone, a-bromo-, preparation of (Knoll & Co.), A., i, 1004.
isoValeryflavvaleric acid, ethyl ester (Zeltner), A., i, 760.
isoValeryl-d-valine, l-a-bromo- (Fischer and Scheibler), A., i, 958.
Valine, active, derivatives of (Fischer and Scheibler), A., i, 957.
isoValine. See a-Methylbutyric acid, l-a-amino.
trans-Valine anhydride (Fischer and Scheibler), A., i, 958.
Valve, new safety (Stoltzenberg), A., ii, 828.
d-Valylglycine and l-Valyl-d-valine and its methyl ester and their hydrochlorides (Fischer and Scheibler), A., i, 958.
Vanadic acid and Vanadates. See under Vanadium.
Vanadium alloys with iron (Vogel and Tammann), A., ii, 502.

Vanadium diflouride (Manchot and Fischer), A., ii, 47.
Vanadic acid, reduction of, by magnesium and zinc (Gooch and Edgar), A., ii, 540.
vanadium, reduction of, by potassium iodide (Warwynski and Mdivani), A., ii, 958.
and chromic acid, iodometric estimation of, in presence of each other (Edgar), A., ii, 889.
and molybdc acid, estimation of, in presence of one another (Edgar), A., ii, 540.
Vanadates, stannometric estimation of (Warwynski and Mdivani), A., ii, 636.
acid, of univalent metals, spitting of (Prandtl and Murschhauser), A., ii, 46.
Hypovanadic acid and some of its compounds (Gain), A., ii, 598.
hydraded, an isomeric modification of (Gain), A., ii, 284.
Vanadium aluminium silicides (Manchot and Fischer), A., ii, 46.
sulphide, naturally-occurring. See Rizopatronita.
Vanadium, estimation of, in iron and steel (Campbell and Woodhams), A., ii, 901.
estimation of, in steel (Blair), A., ii, 900.
and iron, estimation of, in presence of each other (Edgar), A., ii, 736.
simultaneous volumetric estimation of, in ferro-vanadium (Warwynski and Mdivani), A., ii, 736.
Vanillic acid, 2-bromo- (Robertson), T., 792.
Vanillin, preparation of, from guaiacol (Rofslor), A., i, 348.
methylation of (Decker and Koch), A., i, 35.
new isomeride of, from the root of a species of Chlorocodon (Goulding and Pelly), P., 62.
trimethylene ether and its aniline derivative and oxime (Gattermann), A., i, 35.
Vanillinylidene carbamidoxime (Conduché), A., i, 155.
isoVanillinitrile. See Guaiacol, 5-cyano-.
Vanillinyldimethylcarbinol and its dimeride (Behal and Tiffeneau), A., i, 631.
Vanillinyldeneacetone hydrochloride (Francesconi and Cusmano), A., i, 803.
INDEX OF SUBJECTS.

Vanillylideneaminamylideneacetone
(Francesconi and Cusmano), A., i, 802.

Vanthoffite and langbeinite (Nacken),
A., ii, 692.

Vaporisation (v. Jüptner), A., ii, 663, 810.

Vapour density, new method suggested
for determining (Blackman), P., 8; A., ii, 157, 564.

determinations at very high tempera-
tures (v. Wartenberg), A., ii, 86.

use of charcoal in (Dewar and Jones), A., ii, 258.

apparatus, Victor Meyer's, simple form
of release for (Patterson), A., ii, 156.

See also Density.

Vapour pressure and ignition tem-
perature, relation between of inflammable
liquids of low boiling point (Charitschkooff), A., ii, 255.

and osmotic pressure of strong solu-
tions (Calendard), A., ii, 671.

of a volatile solute (Calendard),
A., ii, 1019.

ofsolutions, determination of, with the
Morley gauge (Tower), A., ii, 811.

reciprocal actions of dissolved sub-
stances as deduced from their
(Wroczynski), A., ii, 662.

Vapour pressure interpolation formula,
new (Bose), A., ii, 84.

Vapours, organic, supersaturation and
nuclear condensation of (Laby), A., ii,
797.

Vaso-dilatin
(Meyer), A., ii, 517.

Vegetables, influence of manures on. See
Manurial experiments, Plants, and Soils.

Vegetation, influence of manures on. See
Manurial experiments, Plants, and Soils.

Vegetable spirans, chemical composition
of the skeletal substance of (Henze), A.,
ii, 517.

Velocity of chemical change, of hydro-
lysis, of reactions, and of reduction.
See under Affinity, chemical.

Venom. See Poison.

Veratraldehyde (3:4-dimethoxybenzalde-
hyde) and its azine, synthesis of
(Gattermann), A., i, 33.

preparation of (Decker and Koch),
A., i, 35.

Veratrole, azidine from, and its azine,
oxime, and additive compound with
aniline hydrochloride (Gattermann),
A., i, 33.

4-Veratroyl-5-methoxy-2-methylcou-
maran (v. Kostanecki and Lampe),
A., i, 443.

Veratrylamine and Veratrylaminocetal
(Reichheimer and Schön), A., i,
154.

Veratryldimethylenecarbonil (Béhal and
Tiffeneau), A., i, 631.

Verbenalin from Verbena officinalis
(Bourdier), A., i, 197.

Nesuvius, boric acid in the fumaroles of
(Lacroix), A., ii, 765.

Vetch legumin. See Legumin.

Vicianin, constitution of (Bertrand
and Weisweiller), A., i, 817.

Viellin from the pea, hydrolysis of
(Osborne and Heyl), A., i, 929.

Victoria Blue R (New Victoria Blue),
imino-base of, and its carbinal base
and its ethers (Noeltling and
Phillip), A., i, 295.

Vignin, hydrolysis of (Osborne and
Heyl), A., ii, 744.

Villiaumite from Los Islands (Lacroix),
A., ii, 201.

Vines, danger of using arsenic salts for
(Breteaullau), A., ii, 887; (Mestrezat),
A., ii, 1069.

Vinylacetyltropeine and its platinichlor-
ide (Wolffenstein and Rolle), A.,
i, 282.

o-Vinylphenol (o-hydroxystryrene) and its
bromo- and alkyl-derivatives (Fries
and Fickewirth), A., i, 160.

o-Vinylphenoxacetic acid (Fries and
Fickewirth), A., i, 160.

Vinyltrimethylene. See sipherPentane.

Viola-rutin (viola-quercitrin). See Rutin.

Viridinine from pancreas and its additive
salts (Ackermann), A., i, 1007.

Viscosity and chemical constitution,
relation between (Dunstan and
Thole), T., 1815; P., 213; (Dun-
stan and Stubbs), T., 1919; P.,
224.

and conductivity (Arndt), A., ii, 87;
(Leinicke), A., ii, 251.

of aqueous solutions (Green), T.,
2023, 2049; P., 187.
Viscosity and conductivity of solutions of certain salts in water, methyl alcohol, ethyl alcohol, and acetone, and in binary mixtures of these solvents (Jones and Veazey), A., ii, 259, 260.

diffusion constants, and electrical conductivity, relation between (Pissarjewsky and Karp), A., ii, 566.

and fluidity (Bingham), A., ii, 1017.

and ionic volume (Getman), A., ii, 930.

anomalous, at the clearing point of so-called crystalline liquids (Bose and Conrat), A., ii, 258.

of binary mixtures of organic compounds; formation of molecular compounds in the liquid state (Tsakalotos), A., ii, 260.

of colloidal liquids, influence of electrolytes on the (Albanese), A., ii, 1018.

of colloidal solutions (Woudstra), A., ii, 464.

colloids, effect of electrolytes on the (Gokun), A., ii, 821.

of emulsions and of anisotropic liquids, anomalies in the (Bose), A., ii, 1017.

of lubricating oils (Maberry and Mathews), A., ii, 741.

certain metals and its variation with temperature(Guye and Mintz), A., ii, 930.

of colloidal silver solutions (Woudstra), A., ii, 465, 518.

of solutions (Fawsitt), T., 1004 ; P., 121 ; (Ranken and Taylor), A., ii, 87.

dilute alcoholic solutions (Hirata), A., ii, 930.

of solutions of fatty acids (Tsakalotos), A., i, 498, 598.

“negative,” of aqueous solutions (Taylor and Moore), A., ii, 818.

study of the solutions of some salts exhibiting (Getman), A., ii, 464.

determinations at high temperatures (Fawsitt), T., 1299 ; P., 146 ; A., ii, 358.

Viscosity curve for mixtures of glycerol and water, explanation of the (Carradío), A., ii, 758.

Viscum album (mistletoe), base from (Leprince), A., ii, 58.

inosites of the berries and leaves of (Tannet), A., ii, 58.

Vites aqua-castina, oil from the leaves of (Schimmel & Co.), A., i, 668.

Volatilisation produced by canal rays (Stark), A., ii, 1007.
cathodic. See under Electrochemistry.

Volatility, relative, of certain groups of mixed organic compounds (Henry), A., i, 305, 381.

Volcano of Siroua, in the Morocco Atlas (Gentil), A., ii, 203.

Voltameter. See under Electrochemistry.

Vorobyevite (Vernadsky), A., ii, 855.

W.

Walden’s inversion (McKenzie and Clough), T., 811 ; P., 91 ; (Fischer and Scheibler), A., i, 324, 857.

Wash-bottle and pipette, combined (Hogarth), A., ii, 981.

Water, apparatus for demonstrating the synthesis of (Kempf), A., ii, 480.

action of radium emanation on (Cameron and Ramsay), T., 966, 992 ; P., 132, 183 ; (Rutherford and Royds), A., ii, 1006.

condensation of the vapour of, in presence of radium emanation (Curie), A., ii, 7, 797.

currents in, due to the solution of carbon dioxide (Rebenstorff), A., ii, 490.

the ionisation factor of, in hydrochloric acid solutions (Doumen) A., ii, 252, 349.

decomposition of the vapour of, by electric sparks (Holt and Hopkinson), A., ii, 682.

action of finely-divided metals on (van Ryn), A., ii, 190.

the influence of traces of nitrous gases on the condensation of the vapour of (Pringal), A., ii, 798.

influence of ozone on the condensation of the vapour of (Leithäuser and Pohl), A., ii, 372.

evaporation of solutions of sulphuric acid and (Vailant), A., ii, 460.

Conductivity water, preparation of (Hartley, Campbell, and Poole), T., 428 ; P., 47.

Water of crystallisation as affected by light (McKee and Berkheiser), A., ii, 1003.

use of a vacuum for drying salts containing (Krafft), A., ii, 29.

Natural waters, origin of the green colours of (Spring), A., ii, 369.

Water, constant head of, for laboratories (Muraour), A., ii, 479.
INDEX OF SUBJECTS.

Water:

Drainage waters collected during 1906–7, at Cawnpore, amount and composition of (Hayman), A., ii, 890.

Fresh waters, Scandinavian, humus substances soluble in water from (Aschan), A., i, 250.

Spring and Mineral waters, thermal, gaseous outputs of (Moureu and Biquard), A., ii, 277.

of Agate, Canary Islands, thermal, radioactivity of the (Díaz de Rada), A., ii, 750.

from Castromonte and Puertollano, radioactivity of the (Muñoz del Castillo), A., ii, 550.

from Cucho, radioactivity of the (Muñoz del Castillo), A., ii, 750.

of Fitero Viejo, radioactivity of the mud from the (Díaz de Rada), A., ii, 750.

of Finggi, near Anticoli, physico-chemical investigation of the (Nasini and Levi), A., ii, 401.

of Kissingen, radioactivity of the (Jentsch), A., ii, 9, 143.

of Lavez-les-Bains, radioactivity of the (Sarasin, Guye, and Michelii), A., ii, 143.

of Lerez, radioactivity of the (Muñoz del Castillo), A., ii, 750.

from Martos and Onteniente, radioactivity of the (Díaz de Rada), A., ii, 550.

at Oña, Burgos, radioactivity of the (Muñoz del Castillo), A., ii, 1004.

of Plombières, radioactivity of the (Brochet), A., ii, 143.

of St. Jean de Maurienne, goitrogenic, radioactivity of the (Répin), A., ii, 796.

Swedish, radioactivity of the (Sjögren and Sahlbom), A., ii, 749.

in the Tyrol, radioactivity of the (Bamberger), A., ii, 649.

thermal, of Uriage-les-Bains, Isère, radioactivity of the gases of the (Massol), A., ii, 1004; (Besson), A., ii, 1005.

at Valdemorillo, radioactivity of the (Muñoz del Castillo), A., ii, 1004.

natural, analysis of (Rolloff), A., ii, 281.

physico-chemical analysis of (Hintz and Grünhut), A., ii, 1075.

rapid estimation of carbon dioxide in (Stránsky), A., ii, 225.

Water:

Sea-water, radioactivity of (Joly), A., ii, 246.

amount of dissolved organic carbon compounds in, and their significance in its internal economy (Henze), A., ii, 706.

chemical precipitation of calcium carbonate from (Philippi), A., ii, 302.

estimation of ammonia, nitrates, and nitrites in (Klinger and Klinggen), A., ii, 320.

Sea sediments, radium in deep (Joly), A., ii, 649.

Springs, goitrogenic, radioactivity of (Répin), A., ii, 796, 1058.

Well water, presence of nitrite and ammonia in, and its signification (van Eyk), A., ii, 983.

Water analysis:

plea for uniformity in the analysis of (Noll), A., ii, 435.

analysis of, by means of potassium stearate and phenolphthalein (Blacher and Jacoby), A., ii, 897.

influence of microbes on the composition of (Rouchy), A., ii, 541.

simple form of apparatus for observing the rate of absorption of oxygen by polluted (Adney), A., ii, 781.

estimation of ammonia in (Ronchese), A., ii, 320.

estimation of the hardness of (Tell), A., ii, 535.

estimation of manganese in (Ernyei), A., ii, 133.

limitations of the copper-zinc couple method in estimating nitrates and nitrites in (Purvis and Courtauld), A., ii, 776.

rapid estimation of, in articles of food, &c. (Thörrner), A., ii, 222.

See also, Ice, Snow, and Steam.

Water fennel oil, phellandrene from (Kondakoff), A., i, 665.

Waterglass (Ordway), A., ii, 37.

Water-jet blower, simple (Revington and Rankin), A., ii, 30.

Wax, bees' (Berg), A., ii, 878.

Japanese, acids of high melting point in (Schaal), A., i, 3.

C1H12O2 from Morinda citrifolia (Oesterle and Tisza), A., ii, 527.

Waxes, percentage of iron in (Glikin), A., ii, 407.

See also Psylla wax.

Wohneit cathode. See Cathode under Electrochemistry.
Weight, Landolt’s experiments on change of, in chemical transformation (Laby), A., ii, 170.

of a falling drop and the laws of Tate (Morgan and Stevenson), A., ii, 356; (Morgan and Higgins; Higgins), A., ii, 668.

total, of substances taking part in a chemical reaction, supposed alteration in the (Landolt), A., ii, 366.

Weights, molecular, and critical temperatures of liquids, determination of, by the aid of drop weights (Morgan and Stevenson), A., ii, 356; (Morgan and Higgins; Higgins), A., ii, 668.

heat of fusion, and specific cohesion at the melting point (Walden), A., ii, 1014.

determination of, and the influence of foreign substances on transition temperatures (Dawson and Jackson), T., 344; P., 26.

of molten salts (Lorenz, Kaufler, and Liebmann), A., ii, 1023.

Werner’s theory, criticism of (Friend), T., 269, 1006; P., 14, 122.

Whartonian jelly, silicic acid in (Frauenberger), A., ii, 969.

Wheat, influence of manures on the composition of (Snyder), A., ii, 528.

Göttingen square-head, influence of manures and soil moisture on the disposition and perfection of the ears and the club shape of (Oehmer), A., ii, 726.

Wheat flour. See under Flour.

Wheat seedlings, toxicity of various substances on (Schreiner and Reed), A., ii, 420; (Schreiner and Shorey), A., ii, 889.

White metal, analysis of (Schürmann and Scharffenberg), A., ii, 537.

White precipitate. See Mercure ammonium chloride under Mercury.

Wilksite, composition of (Crookes), A., ii, 695.

Wine, malic acid in the production of (Mestrezat), A., ii, 723.

fermentation of malic acid in the production of (Rosenstiehl), A., ii, 772.

formation of acetyl methylcarbinol in the acid fermentation of (Pastureau), A., ii, 138.

influence of the sterilisation temperature of grape juice and of the fermentation temperature on the “bouquet” of (Rosenstiehl), A., ii, 773.

Wine, quantity of arsenic in, from vines which have been treated with arsenical washes (Breteau), A., ii, 887; (Mestrezat), A., ii, 1069.

citric acid in (Hubert), A., ii, 544.

the natural citric acid of (Dupont), A., ii, 904.

fluorine in (Carles), A., ii, 318.

lactic acid in (Paris), A., ii, 542.

natural and added tartaric acid in natural (Astruc and Mahoux), A., ii, 992.

and alcohol, action of, on frogs (Nazari), A., ii, 973.

physico-chemical analysis of (Dutoit and Duboux), A., ii, 781, 892.

detection and estimation of free mineral acids in red (Astre), A., ii, 892.

detection of citric acid in (Favrel; Astruc; Deniges), A., ii, 640.

detection of fluorine compounds in (Vandam), A., ii, 63, 776.

detection of nitrates in (Maisiglia), A., ii, 894.

estimation of the acidity of (Guérin), A., ii, 330; (Favrel), A., ii, 903.

new method of estimating the fixed and volatile acids in (Pozzi-Escot), A., ii, 904.

estimation of the most important acids in, in presence of alcohol and glycero (Heiduschka and Quincke), A., ii, 73.

estimation of alcohol in (Duboux and Dutoit), A., ii, 136.

estimation of sulphur dioxide in (Menski), A., ii, 63.

estimation of tannins in white (Koenner), A., ii, 240.

estimation of tartaric acid in, by evaporation (Mestrezat), A., ii, 1078.

Wine lees, estimation of tartaric acid in (Pozzi-Escot), A., ii, 740.

Witherite, specific heat of (Latshenko), A., ii, 758.

Witte’s peptone. See Peptone.

Wollastonite—Rodenite, freezing point curve for the system (Ginsberg), A., ii, 842.

Women, question of admitting, to the Fellowship of the Society, P., 203, 277.

INDEX OF SUBJECTS.

Wood oil, Japanese (KAMETAKA), A., i, 850.

X.

X-rays. See Röntgen rays under Photochemistry.

Xanthen, action of benzoyl chloride on (Heller and V. Kostanecki), A., i, 445.

Xanthhydrrol, action of carbamide, thiocarbamide, urethane, and some amides on (Fosse), A., i, 41.

Xanthic acid (Ragg), A., i, 604.

Xanthine as a cause of fever (Mandel), A., ii, 54.

Xanthine bases (Schmidt), A., i, 45. preparation of hydroxyalkyl derivatives of (Farbenfabriken Vorm. F. Bayer & Co.), A., i, 475, 703.

Xanthines, hydrolysis of (Tafel and Mayer), A., i, 742.

Xanthomericol and its diacetyl derivative (Power and Salway), A., ii, 418.

Xanthophanic acid (Liebermann and Lindenbaum), A., i, 548.

Xanthyl derivatives, new (Silberrad and Roy), P., 204.

Xenon, krypton, helium, and neon, percentage of, in the atmosphere (Ramsay), A., ii, 683.

density of (Moore), T., 2181; P., 272.

Xenotine, absorption spectra of, and the changes they undergo at the temperatures of liquefaction and solidification of hydrogen (Becquerel and Onnes), A., ii, 338.

α-Xylene, nitro-derivatives of (Crossley and Renouf), P., 58.

τri-nitro-derivatives (Crossley and Renouf), T., 646.

m-Xylene, reaction of, with ethyl diazoacetate (Buchner and Brück), A., i, 87.

m-Xylene, α-tetrachloro- (Bielecki), A., i, 424.

p-Xylene disulphoxide (Knoevenagel and Polack), A., i, 971.

p-Xylene, α-dinitro-, diazobenzene derivative of (Ponzi and Charrier), A., i, 582.

m-Xylene-4-azo-3-cyano- and -3-carboxy-β-naphthol-6-sulphonic acids, sodium salts (Lange), A., i, 300.

m-Xyleneazo-ββ-dinaphthylamine (Fischer and Strauss), A., i, 222.

4-m-Xyleneazo-3-methyl-5-pyrazolone and its 1-benzoyl derivative (Blow and Schaub), A., i, 705.

m-Xyleneazo-orcinol, 5-bromo- (Orton and Everett), T., 1020.

m-Xylene-4-aæroleorcinol, 5-bromo- (Orton and Everett), T., 1019.

Xylenazo-. See also Xylylazo-.

p-Xylene-2-sulphonic acid, alkaloidal salts, and their rotatory power (Hilditch), T., 1621.

Xylenesulphonic acids, m-, p-, preparation of (Knoevenagel and Kenner), A., i, 971.

p-Xylenesulphonic anhydride, preparation of (Knoevenagel and Polack), A., i, 971.

m-Xylene-4-sulphonic acid, 2,6-dinitro-, derivatives of (Karslake and Morgan), A., i, 410.

p-Xylene-2-sulphonic acid, alkaloidal salts, and their rotatory power (Hilditch), T., 1621.

m-5-Xyleneol methyl ether, sulphination of (Smiles and L. Rossignol), T., 761.

methyl and ethyl ethers (Gattermann), A., i, 33.

p-Xyleneol ethylene ether and its dialdehyde (Gattermann), A., i, 35.

Xylenols, comarins from (Clayton) T., 2018.

m-Xyldine, acetyl derivative. See Aceto-m-xylidine.

m-Xyldine, trichloro- (Mannino and Donato), A., i, 826.

Xyldines, action of dichloroacetic acid on (Heller and Leyden), A., i, 218.

p-Xyloquinone, dihydroxy-, diacetate of (Fichter and Weiss), A., i, 659.

Xylose derivatives, synthesis of (Ryan and Ebrill), A., i, 716.

Xylose-m-nitrophenylhydrazone (Reclaire), A., i, 1014.

Xylylaldehyde and its derivatives (Sawariac), A., i, 189.

as-m-Xylylaniline, α-hydroxy-, and its N-acetyl derivative (Anselmino), A., i, 239.

m-Xylylazoacetoacetic acid, ethyl ester, and its benzoylhydrazone (Blow and Schaub), A., i, 705.
INDEX OF SUBJECTS.

0-Xylene, Me : Me = 1:2; m-xylene, Me : Me = 1:3; p-xylene, Me : Me = 1:4.)

Ytrrium, phenomenon attributable to positive electrons in the spark spectra of (Bequerel), A., ii, 334.

Yttrium hydroxide, heterogeneous colloidal (Szlard), A., ii, 197.

Yttrium earths (Lenher and Benner), A., ii, 385.

new method for the separation of (James), A., ii, 190.

See Cerium metals and Earths, rare.

Y.

Yangonin, Yangonic acid and its acetyl derivative, and Yangonol and its benzoyl derivative (Winzheimer), A., i, 805.

Yeast, sensitising action of fluorescent substances in (v. Tappeiner, Kurzmann, and Locher), A., i, 239.

behaviour of cultivated varieties of, in composite nutrient solutions (Henneberg), A., ii, 416.

can betaine be regarded as a source of nitrogen for? (Stanek and Misskovsky), A., ii, 416.

formation of glycogen by (Pavy and Bywaters), A., ii, 56.

sugar formation and other fermentative processes in (Salkowski), A., ii, 215.

beer, action of, on acid amides (Effront), A., i, 491.

expressed, co-enzyme of, in juice (Buchner and Klattet), A., i, 380.

Yeast cellulose, yeast dextrose, and yeast gum (Meigen and Spreng), A., ii, 315.

Yeast juice, properties of (Buchner and Klattet), A., i, 589.

action of the electric current on (Resenschek), A., i, 491.

the alcoholic ferment of (Harden and Young), A., i, 500.

Yeast press juice, sensitising action of fluorescent substances in (v. Tappeiner, Kurzmann, and Locher), A., i, 239.

Yeastas, part played by, in the formation of aldehydes (Trillat and Sauton), A., ii, 615, 722.

formation and disappearance of acet-aldehyde under the influence of (Trillat and Sauton), A., ii, 615.

Yerba Buena. See Micrococcus Chaimissonis.

Yang-ylang oil (Bacon), A., i, 815.

Yohimbine, physiological actions of (Gunis; Tait and Gunis), A., ii, 412.

Yterbium, resolution of, into its components (v. Weisbach), A., ii, 591; (Urbain), A., ii, 849.

Z.

Zeeman phenomenon. See under Photocchemistry.

Zeoit from Japan (Jimbo), A., ii, 704.

of Montresta, Sardinia (Pelacani), A., ii, 864.

Zinc, electrolytic valve action of (Sulze), A., ii, 560.

heating effects produced by Röntgen rays in (Bumstead), A., ii, 342.

action of oxygen on copper, tin, and, and on its alloys with copper (Jordis and Rosenhaupt), A., ii, 107.

favorable influence of small quantities of, in the growth of Sterigmatocystis nigra (Javillier), A., ii, 124.

Zinc alloys with aluminium, hardness of (Saposhnikoff), A., ii, 234.

with calcium (Donski), A., ii, 278.

with cobalt (Lewkonja), A., ii, 853.

with copper, action of oxygen on (Jordis and Rosenhaupt), A., ii, 107.

heat treatment of (Bengough and Hudson), A., ii, 186.

with copper and nickel, constitution of (Tafel), A., ii, 846.

with nickel (Tafel), A., ii, 105, 846; (Voss), A., ii, 196.

amalgamated (Van Deventer), A., ii, 591.

Zinc salts, abnormal behaviour of, on hydrolysis (Denham), A., ii, 380.

action of hydrogen sulphide on alkaline solutions of (McCay), A., ii, 431.

Zinc bromide and chloride, double, with the alkalis (Epcharm), A., ii, 693.

carbonate, action of, on formaldehyde solutions (Lon), A., i, 715.

carbonates, basic (Mikusch), A., ii, 185.
INDEX OF SUBJECTS.

Zinc ammonium chromates (Gröger), A., ii, 691.
hyposulphite, dry, direct production of (Chemische Fabrik Grünauf, Landshoff, & Meyer), A., ii, 185.
hydroxylamite (Ebler and Schott), A., ii, 1030.
phosphates from Rhodesia (Spencer), A., ii, 397.
phosphides (Jolibois), A., ii, 1037.
sulphate, electrical conductivity in systems containing ammonia, water, and (Shumakoff), A., ii, 457.
sulphide, mixtures of, with other sulphides (Friedrich and Schoen), A., ii, 281.

Zinc organic compounds, mixed, synthesis with (Blaise), A., i, 78; (Blaise and Herman), A., i, 248.
Zinc allyl iodide, action of, on the anhydrides of monobasic acids (Saytzeff), A., i, 73.
mercuric cyanide, formula of (Dunstan), P., 135.

Zinc, detection of small quantities of, electrochemically (Neumann), A., ii, 67.
estimation of (Thornewell), A., ii, 68.
estimation of very small quantities of (Bertrand and Javillier), A., ii, 67.
estimation of, by electrolysis (Frary), A., ii, 68.
estimation of, volumetrically (Hassreidter), A., ii, 226; (Keen), A., ii, 431; (Stone), A., ii, 632.

Zinc, electrolytic separation of nickel and (Foerster and Treadwell; Fischer), A., ii, 324.
Zirconia. See Zirconium oxide.
Zirconium, colloidal (Wedekind and Lewis), A., ii, 501.
quantitative spectra of (Leonard), A., ii, 645.
atomic heat and atomic volume of (Wedekind and Lewis), P., 170.
Zirconium tetrachloride, reaction of, with mercury phenyl (Peters), A., i, 1032.
tetrafluoride, preparation and properties of (Wolter), A., ii, 701.
hydroxide, colloidal (Szilard), A., ii, 45, 197.
oxide (zirconia), reduction of, by carbon (Greenwood), T., 1493; P., 188.
free from iron, natural (Wedekind), A., ii, 1046.
phosphide (Gewecke), A., ii, 597.
silicate. See Malacite.
Zirconium and titanium, simultaneous precipitation of, in presence of iron (Dittrich and Freund), A., ii, 134.
separation of, from titanium (Dittrich and Freund), A., ii, 134.
separation of thorium, titanium, and, from iron (Dittrich and Freund), A., ii, 135.
Zirconium minerals, radioactive, argon in (v. Antropoff), A., ii, 943.
Zymase, formation of, in yeast (Buchner and Klatte), A., i, 589.
ERRATA.

Collective Index, 1873—1882 (Authors).

Page  Line  for "773" read "173."
259  11 col. i  

Part I.

33  9  for "COOEt·C(OH)(CO·NHPh)·C(OH)(CO·NHPh)·COOEt"  read "COOEt·CH(O·CO·NHPh)·CH(O·CO·NHPh)·COOEt."

Vol. LXXIV (Abstr., 1898).

Part I.

477  1  for "Methoxytolualdehyde" read "Ethoxytolualdehyde."
477  2  delete "whilst the isomeride."
477  3  for ":OEt" read ":OMe."
477  3  delete "third."
477  4  for "OEt" read "OMe."

Collective Index, 1893—1902.

Part II (Subjects).

667  17 col. ii  insert "Ethoxytolualdehyde (Gattermann and Frenzel), 1898, i, 477."
1001  5  ii  for "phenyltoluidine" read "phenyltolylanine."
1257  24  i  delete "See also Methyldiphenylamine."

Part I.

336  12)  for "arylsulphonates" read "arylsulphinates."
337  20  for "arylsulphonates" read "arylsulphinates."

Part II

755  5*, 7*, 9*, 11*, 19*  for "rice" read "rye."

Part I.

640  9*  for "Georg" read "Wilhelm."
641  1  for "Georg" read "Wilhelm."

Part II.

547  12*  for "the sulphide" read "iron."
973  17 col. i  for "Georg" read "Wilhelm."
973  20  for "Georg" read "Wilhelm."

* From bottom.
**ERRATA (continued).**

**Vol. XCI (Abstr., 1907).**

**Part I.**

Page Line for “2-Nitroisophthalic acid” read “2-Nitroisophthalic acid.”

137 1

“phenylrhodanic” read “anilinorhodanic.”

509 9 “hexahydro-m-toluic acid” read “1-methylcyclohexane-2-carboxylic acid.”

**Part II (Index).**

1009 19* col. ii for “662” read “622.”

1059 10 ii “Köffler” read “Löffler.”

1074 2 ii for “Mayer” read “Meyer.”

1076 10 ii insert “an attempt to synthesise collidine, A., ii, 440.”

**Vol. XCIV (Abstr., 1908).**

**Part I.**

44 5* “C_{12}H_{26}N_{2}MeI_3HI,H_2O” read “C_{12}H_{26}N_{2}I_3HI,H_2O.”

249 5 “CMe_2CO·CMe:CH_2” read “CHMe_2CO·CMe:CH_2.”

266 19* “diethylaminooctyl” read “diethylaminopropyl.”

275 8* “2-Phenylpyrrolidine” read “2-Pheny1pyrroline.”

288 13, 14 “3-phenyl-1-methyl-2-quino1ine” read “3-phenyl-1-methyl-2-quino1ine.”

345 16* “Gialdino” read “Gialdini.”

406 11* “1-isopropylhexane-2-one” read “1-isopropylcyclohexane-2-one.”

408 21 “Robiker” read “Rolker.”

457 20* “4-nitro-4-hydroxypolenamine” read “4-nitro-4-hydroxypolenamine.”

474 4 “aminophenylthiocarbamide” read “aminophenylcarbamide.”

494 10* “HCl,C1” read “CHCl_3.”

590 6* “NMe_2·C_6H_4·As(OH)·ONa” read “NMe_2·C_6H_4·AsO(OH)·ONa.”

591 20, 21 “crystallising” read “the sodium salt crystallises.”

591 5* “Kuhn” read “Kahn.”

652 21 “NH·C_6H_5(CO_2Me)_2” read “N·C_6H_5(CO_2Me)_2”

687 4 “1899” read “1889.”

692 21* “VIII” read “XXIX.”

765 17 “Funia”

773 7* for “a-Bromoisohexyl-β-aminobutyric acid” read “a-Bromoisohexyl-β-aminobutyric acid.”

809 1*

810 13

810 17 “dl-fenchene” read “D-l-fenchene.”

810 23

811 1

810 4

810 5 “dl-hydroxyfenchene acid” read “D-l-hydroxyfenchene acid.”

811 6

810 12* “dd-fenchene” read “Dd-fenchene.”

927 1, 2, 3 should read “p-Nitrobenzenesalicylic acid, m. p. 256°; the constitution is proved by its yielding aminosalicylic acid and p-phenylendiamine when reduced by sodium hyposulphite in hot aqueous solution.”

927 13 “hydrogen” read “hypo.”

* From bottom.
